The ROD indicates an average of the purchased and variable assets for the EWA could be 380 TAF. This average includes 185 TAF in purchased assets, 70 TAF from relaxation of the E/I ratio and (b)(2) releases that reach the Delta, 500 cfs of dedicated capacity at Banks pumping plant (estimated at 50 TAF), and use of one-half of the excess capacity at Banks (estimated at 75 TAF).

The 380 TAF number contained in the ROD is potentially misleading because it includes both capacity and real water assets. These two categories cannot be added to provide a meaningful estimate of the average water budget. A more accurate reflection of the average quantity of water available would be to add only those assets that provide water. Table 4 shows the variable assets as defined in the ROD, highlights those that actually provide water, and quantifies the amount of water that has been obtained in 2001 and 2002.

The combination of purchased and variable assets was intended, on average, to provide sufficient assets to meet fish protection needs without reducing deliveries to the contractors. Under certain hydrological conditions, such as these past two dry years, some of the variable assets would not produce any water. In addition, variable tools

such as E/I relaxation produce water in relation to the management of this particular asset.

Table 4
Variable Assets in the CALFED ROD Compared to Actual EWA Benefits in 2001 and 2002

Variable Asset	CALFED ROD Average in TAF	2001 Actual in TAF	2002 Actual in TAF
Variation of E/I ratio	40	2	79
Half of (b)(2) releases that reach the Delta	30	46	3
500 CFS dedicated capacity at SWP Banks PP	55[1]	0 (Capacity only)	0 (Capacity only)
Joint Point Of Diversion (use of excess capacity at SWP Banks PP)	75[2]	0 (Capacity only	0 (Capacity only)
ROD Total	195		
Actual expected Water Total on Average	70	48	82 (20 was retained past San Luis High Point)

Based on this analysis of variable assets and the management of the variable tools during the last two dry years, the EWA can reliably expect to get limited utility from variable assets in years with hydrologic conditions similar to 2001 and 2002. More assets would be possible from the Joint Point of Diversion in wetter years or if the EWA (1) carried debt into the winter in San Luis Reservoir, or (2) had a reliable location south of the Delta where water could be temporarily stored and economically retrieved in the same or subsequent years. More assets could also be obtained as demonstrated with increased management of the E/I relaxation by the Management Agencies in 2002.

[1] Capacity - Represents a quantity expected to be moved using dedicated 500 cfs at Banks from the summer time capability above the 6,680 cfs that was provided in the COE permit until late 2003. A request to extend this capacity has been submitted to the COE by DWR.

[2] Capacity - Represents one half of the available excess capacity at the SWP Banks pumping plant. Under balanced conditions, this asset is only capacity and the EWA must supply water it has purchased or stored upstream to take advantage of this EWA asset. In normal and wet years this asset can result in water during excess conditions for EWA provided that EWA has an existing debt in San Luis or EWA has a location other than San Luis to store this water.

In the near future, acquisition of rights to additional short-term surface storage should be considered by the EWA to achieve this storage capability and protect assets from loss in wet periods. Groundwater storage costs are estimated at about $140 to place and retrieve water in addition to any costs of acquiring the water to be placed in storage and current offers do not allow the EWA to retrieve this stored water in years drier than 60 % SWP allocation years.

Another method to preserve a portion of variable assets is an unbalanced exchange as was done in 2002. In this case a 2 for 1 exchange was made where 2 units of EWA water were provided to SWP contractors prior to high point in San Luis and these users returned 1 unit of water to the EWA after high point. There was no out-of-pocket dollar cost to the EWA for this action, yet it provided "temporary storage" for 20,000 acre-feet, half the assets in San Luis at the time.

The Management Agencies are requesting "place holders" for about 150-300 TAF of fish actions before high point in San Luis Reservoir in most years. If these actions are taken and San Luis Reservoir fills and additional pumping capacity beyond SWP Article 21 demand is available, EWA debt would be extinguished in San Luis Reservoir to the extent of the additional pumping. In such an event, the EWA could gain additional assets at the rather modest cost of pumping the water from the Delta.

However, if San Luis Reservoir does not fill or there is no extra pumping capacity to extinguish the debt, as is most likely in the drier years, then the debt would not be extinguished and the EWA would not have gained any assets. However, experience over the past two years indicates that large placeholders in dry years may not be needed due to lower export rates in these years. For planning purposes, the estimation of variable assets needs to be keyed to the filling of San Luis Reservoir and the availability of pumping beyond the demand for Article 21 water by the SWP contractors in the wetter years. At present, it is unknown how much EWA can accrue.

Thus for the purposes of evaluating the EWA's ability to provide the assets that will be required to satisfy the assumed placeholders for fish actions, it is assumed that some benefits would accrue to the EWA from the extinguishment of debt in San Luis Reservoir in wetter years. In drier years, pumping is less, and therefore EWA placeholders are reduced, the need for large variable assets is less, and the ability to extinguish EWA water debt in San Luis Reservoir is also less (see section V).

J. The EWA Source Shift

Source shift arrangements are EWA assets that are required by the CALFED ROD. Source shifting is a way for the EWA to temporarily borrow water from a water user, while they draw on an alternative (often local) source of water and temporarily reduce their SWP or CVP deliveries. Source shifting is initiated in the spring and summer before San Luis low point, and completed by paying back the water after low point is no longer a concern.

The source shift is a valuable tool for EWA in some years. The largest use of the source shift is to allow the EWA to avoid aggravating water quality or water supply around the low point in San Luis that might otherwise occur if the EWA owed water to the projects at that time.

The source shift allows the EWA to shift demand around low point issues and to carry debt into the fall and winter. By avoiding the need to pay back previous operational curtailments prior to low point, source shifting allows the return of water to the SWP and CVP after August, allowing more efficient use of export capacity and providing extended instream fishery benefits. The source shift can be viewed as a "bridge loan" of water because it must be paid back within a specified period of time.

One issue with the source shift is that it has proven to be just as expensive as purchasing water upstream of the Delta. It cost as much to "rent" this water for four months in 2001 as it did to purchase an equivalent volume upstream of the Delta, but it had a separate purpose and in essence provided a different value to the EWA. Although the EWA will obtain the required contract each year and pay the option fee, the EWA will activate the source shift only when reasonable forecasts of the EWA's impact on San Luis Reservoir storage indicates storage levels of concern, or when the use of water for fishery actions has been unusually high and the EWA needs to carry debt into the following winter.

K. Borrowing and Long-Term Storage

The EWA may borrow water from the SWP or CVP to achieve fishery protections, provided that such borrowing will not result in any reduction in CVP or SWP deliveries. Borrowing is allowed if it will not cause a reduction in deliveries in the year of borrowing or in the subsequent water year. The EWA operating principles anticipate that an EWA asset will be in place as collateral to allow the borrowing of water both within and between years. The ROD specifies that a one-time asset of 200 TAF of stored water or its functional equivalent be provided from south-of Delta sources.

During the EWA "gaming" as much as 100 TAF of this collateral was used to pay back borrowing because there were not sufficient assets in the following year to pay back the EWA debt. Also, the water projects are allowed to borrow water from the EWA when it is agreeable to all parties. In both cases the same principles apply: A proposal is made that includes:(1) the quantity of water to be borrowed, (2) the term of the loan, and (3) specific criteria for repaying the water to the lender.

As stated above, the EWA Operating Principles provided that 200 TAF of stored water (or its functional equivalent) would be provided for the EWA. During the first year of EWA operation, insufficient funds were available to acquire both the 200 TAF of storage space and water. A decision was made in 2001 for the EWA to purchase more than 100 TAF of water above the 185 TAF target in the ROD. This additional water served as the functional equivalent of the 200 TAF of storage that year.

This use of functional equivalency in the first year of the EWA allowed the program to provide sufficient assets to obtain ESA commitments in the absence of long-term environmental documentation covering the acquisition and operation of stored assets, and to remain within the budget constraints of the EWA. In 2002, the EWA purchased approximately 242 TAF of water.

In 2002, the Project Agencies allowed borrowing that is functionally equivalent to this EWA asset and its prudent repayment under the following conditions. These conditions were established in the EWA protocols for 2002 and continue in subsequent years. These protocols provide that in any given year, up to 100 TAF may be borrowed against the subsequent year EWA assets provided the following:

1. The borrowed assets are paid back to the Projects. This occurs when:
   (1) variable assets are used to pay back the debt as they accrue during the next year, or
   (2) hydrology is sufficient to allow San Luis Reservoir to be filled to the level it would have been absent EWA actions that required borrowing.
2. The borrowed assets may be carried over into a subsequent year beyond 2003 if the Project Agencies determine such action:
   (1) will not impact CVP/SWP allocations in 2003 or
   (2) the EWA can provide sufficient source shifting to avoid impacting storage in San Luis Reservoir at its low point in 2003.
3. Sufficient funding must be provided to acquire the necessary purchased assets for 2003 (185 TAF) plus additional water to repay the amount borrowed. If funding is insufficient to acquire the necessary assets and repay debt, and it is not possible to carryover the debt to 2004, the Project Agencies and Management Agencies will meet to consider alternative repayment options. The objective for both the Project and Management Agencies is to ensure continued EWA operations.

This arrangement of functional equivalence for the 200 TAF of storage will be sought for 2003.

V. EWA Fish Actions: Placeholders for EWA Expenditures

Along with the targets for EWA purchased assets, a set of placeholders is necessary for expected expenditure of EWA assets on a monthly basis during the year. The schedule of expected expenditures allows the fishery agencies to assess their water spending during the year and to make decisions to conserve water for later periods based on expected needs.

The Management Agencies have developed placeholders for 2003 that recognize hydrologic variability, the uncertainty of the quantity of variable assets, and current

budget uncertainties. For a dry hydrology scenario, namely a 90 percent exceedance hydrology (that is a year that would be among the 10 percent of the driest years, where stream runoff would be equaled or exceeded 90 percent of the time), placeholders of 230 TAF have been assumed.

In wetter hydrologies, namely a 50 percent exceedance hydrology, placeholders of 450 TAF are identified. This level of assets can be provided by the EWA if San Luis Reservoir fills and spills EWA debt, as previously described.

This water acquisition strategy incorporates assumed placeholders for water expenditures based on the recommended increase in asset purchases, the recognition that variable assets do not in all cases provide water, and the use of the source shift agreements to carry debt from one year to the next. The placeholders are assumed to reflect the coordination with (b)(2) assets. The annual total placeholders for EWA in 2003 based on these assumptions are shown in Table 5. In addition to the placeholders shown, the projects may agree to allow the EWA to carry indebtedness to the projects into the following year with the expectation that the debt would be repaid without affecting project water supplies.

Table 5
EWA Place Holders for 2003 (in TAF)

Year Type	Purchased EWA Assets Delivered	Estimated Variable Assets	Source shift to carry Debt if needed	Total EWA Place Holders
Critical and Dry	210	50	100	230
Normal and Wet	240	50-150 (1)	100	450

(1) Based on extinguishing EWA debt in San Luis Reservoir in wetter years

VI. Recap of EWA in 2001 and 2002

In the first two years the concept of the EWA presented in the CALFED ROD has become a reality in providing additional protection to sensitive Bay/Delta fish species and obtaining the ESA commitments to stabilize the water supplies of the SWP and CVP. Even though 2002 was a dry year (almost a below normal year) both SWP and CVP allocations by late summer to their users south and west of the Delta were at least 70% of contractor requests. Although the EWA has faced many challenges over these past two years, it has been a success.

Table 6 summarizes the level of EWA purchases and variable assets that were obtained in 2001 and 2002 respectively. Table 7 is a summary of the EWA budget each year and the actual costs of implementing the EWA. In the first two years the EWA has achieved over 530 TAF of fishery actions to better protect fish and purchased over 550 TAF of water to replace the water lost from these actions at a cost of about $90 Million.

The average cost of water was about $179 per acre-foot in 2001, which was a dry year resulting in a 39% allocation by the SWP and a 49% allocation for CVP agricultural users south of Delta. In 2002, a wetter but still a dry-to-below-normal year when allocations of 70% were made by both the SWP and CVP, the average price paid for water was about $118 per acre-foot. The decrease in average price from 2001 to 2002 was likely a result of the wetter hydrologic conditions in 2002, more aggressive negotiations by water acquisition staff, and the fact that first year prices were higher simply because of the short timeline to implement the EWA and purchase large amounts of water. Future prices will reflect hydrologic conditions and competition for limited supplies of water as new buyers enter the market.

During 2002, the water purchase strategy reflected in this document was being developed which refocused the water-buying pattern from that established in the ROD in an effort to decrease costs. While costs for purchasing assets for the EWA has been within projections prepared in spring and summer of 2000, the approved EWA budget has not been what was requested. Nevertheless, the EWA has been able to stay within its budget each year and has achieved a window of peace in the constant conflict between increased protection of fish in the Bay/Delta Estuary and the reliability of supply of water for uses south and west of the Delta.

Table 6 - EWA in 2001 and 2002

ASSETS ACQUIRED	**2001 (TAF)**	**2002 (TAF)**
--Purchase UOD	105	145
• Conveyance and Carriage Costs	- 17	- 31
--Purchased SOD		
• State	+159	+ 37
• Federal (in kind in 2001)	+ 72	+ 60

Notice of Preparation/Notice of Intent

Appendix I

NOTICE OF PREPARATION

MAY 3 1 2002

To: _____

_____
(Address)

_____

From: California Department of Water Resources

Environmental Services Office
(Address)
3251 S Street, Sacramento, CA 95816

Subject: **Notice of Preparation of a Draft Environmental Impact Report**

California Department of Water Resources will be the Lead Agency and will prepare an environmental impact report for the project identified below. We need to know the views of your agency as to the scope and content of the environmental information which is germane to your agency's statutory responsibilities in connection with the proposed project. Your agency will need to use the EIR prepared by our agency when considering your permit or other approval for the project.

The project description, location, and the potential environmental effects are contained in the attached materials. A copy of the Initial Study (☐ is ☒ is not) attached.

Due to the time limits mandated by State law, your response must be sent at the earliest possible date but not later than 30 days after receipt of this notice.

Please send your response to Delores Brown, Environmental Program Manager at the address shown above. We will need the name for a contact person in your **agency**.

On July 10, 2001, a Notice of Preparation of a Draft Environmental Impact Report/Environmental Impact Statement for the Environmental Water Account was filed with the State Clearinghouse (SCH No. 1996032083). Since that date, conditions that defined the baseline have changed. This revised Notice of Preparation reflects those changes, and clarifies that the purchase of Tier 3 assets will also be addressed as part of the environmental analysis.

Project Description

Pursuant to the California Environmental Quality Act (CEQA) and the National Environmental Policy Act (NEPA), the California Department of Water Resources (DWR) and the Bureau of Reclamation (Reclamation) will prepare an EIR/EIS for implementing the Environmental Water Account (EWA) as described in the Programmatic Record of Decision for the CALFED Bay-Delta Program, dated August 28, 2000. A draft Environmental Impact Report/Environmental Impact Statement (EIR/EIS) is expected to be available in late summer 2002.

The CALFED Bay-Delta Program is a long-term comprehensive plan to restore ecological health and improve water management for beneficial uses in the San Francisco Bay/Sacramento-San Joaquin Delta (Bay-Delta) estuary system. The agencies that signed the Record of Decision/Notice of Determination (ROD) for the *Final Programmatic Environmental Impact Statement/Environmental Impact Report* on August 28, 2000 committed to implement the CALFED Bay Delta Program. The Environmental Water Account (EWA) is one component of the long-term comprehensive plan adopted in the CALFED Bay-Delta Program ROD.

The EWA was established to provide a supplemental water supply for the protection and recovery of fish beyond what currently exists through the pre-CALFED Program environmental baseline (Tier 1). As part of the Multi-Species Conservation Strategy Conservation Agreement and the U.S. Fish and Wildlife Service and National Marine Fisheries Service biological opinions, the CALFED agencies have committed to specified conditions and legal requirements based on the availability of three tiers of assets or alternative sources of project water supply. The components of each tier are described below.

Tier 1, as defined in the ROD, included the following regulatory baseline programs to provide a level of fishery protection:

- 1993 Winter-run Biological Opinion (NMFS);
- 1995 Delta Water Quality Control Plan, State Water Resources Control Board (SWRCB);
- 1995 Delta Smelt Biological Opinion (USFWS);
- management of the full 800,000 acre-feet of CVP yield pursuant to Section 3406(b)(2) (or "(b)(2) Water") of the Central Valley Project Improvement Act (CVPIA); and
- other environmental protections, including Level 2 refuge water supplies as required by the CVPIA.

On March 20, 2002, the U.S. District Court for the Eastern District of California issued a final partial judgment concluding that the Department of Interior must modify components of its methodology for accounting for the 800,000 acre-feet of CVP water supplies dedicated to environmental purposes. While the judgment has been appealed, the Department of Interior (Interior) is considering how its accounting methods and certain changes may be made consistent with the final partial judgment. These possible changes will reduce Interior's flexibility in utilizing the 800,000 acre-feet in upstream reaches of CVP-controlled streams under some hydrologic conditions. A portion of some upstream releases may be charged against EWA variable assets included as part of Tier 2, described below. Also, EWA assets described below may be used to supplement fishery protection measures previously taken as part of Tier 1 operations that are no longer taken as a result of the new accounting methods. Incorporation of these methods into the Existing Conditions is necessary to accurately describe the potential use and impacts of the EWA in the EIR/EIS.

Tier 2 consists of the assets in the EWA combined with the benefits of the Ecosystem Restoration Program. The EWA is a cooperative management program whose purpose is to provide protection to the fish of the Bay-Delta estuary through environmentally beneficial changes in project operations at no uncompensated water cost to the projects' water users. The EWA involves five CALFED agencies that have shared responsibility for implementing the EWA. The three management agencies, the U.S. Fish and Wildlife Service (USFWS), the National Marine Fisheries Service (NMFS), and the California Department of Fish and Game (DFG) have responsibility for determining how to manage

the EWA assets to benefit long-term survival of fish species, including those listed under the State and Federal Endangered Species Acts. The two Project Agencies are DWR and Reclamation. The Project Agencies will cooperate with the Management Agencies in administering the EWA, will have primary responsibility for banking, borrowing, transferring, making operational changes, and arranging for the conveyance of EWA assets.

This approach to fish protection requires the acquisition of alternative sources of project water supply, called "EWA assets," which will be used to augment streamflows, Delta outflows, to modify exports to provide fishery benefits, and to replace the regular project water supply interrupted by the changes to project operations. The replacement water will compensate for reductions in deliveries relative to existing facilities, project operations and the regulatory baseline that result from EWA actions.

The EWA will be implemented over four years unless the Managing Agencies and Project Agencies decide the program should be extended to include future years. The initial EWA assets will be acquired to meet the overall objective of the ROD as identified in Table 1. Assets acquired for the EWA may vary from year to year depending on hydrologic and regulatory conditions, and are therefore not certain.

Table 1. EWA Assets In Accordance with the ROD

Action Description	Water Available Annually (Average)
SWP Pumping of (b)(2)/ERP Upstream Releases[1]	40,000 acre-feet[2]
EWA Use of Joint Point[3]	75,000 acre-feet
Export/Inflow Ratio Flexibility	30,000 acre-feet
500 cfs SWP Pumping Increase	50,000 acre-feet
Purchases – South of Delta	150,000 acre-feet
Purchases – North of Delta[4]	35,000 acre-feet
TOTAL	380,000 acre-feet
Storage acquisition	200,000 acre-feet of storage, filled; acquired in Year 1[5]
Source Shifting agreement	100,000 acre-feet

The EWA will rely on the operation of the SWP, CVP, and the facilities of certain local and regional water agencies to transport or store acquired EWA assets. Several processes

[1] The EWA and the SWP will share equally the (b)(2) and ERP upstream releases pumped by the SWP after they have served their (b)(2) and ERP purposes.
[2] The amount of water derived from the first four actions will vary based on hydrologic conditions.
[3] The EWA will share access to joint point, with the CVP receiving 50% of the benefits.
[4] This is the amount of water targeted for the first year; higher amounts are anticipated in subsequent years. North of Delta assets assume a twenty- percent carriage loss. The actual quantity of water acquired will be approximately 45,000 acre-feet.
[5] Of the 200,000, 100,000 acre-feet would be retrievable within the year.

may be used to acquire EWA assets and/or functional equivalent sources of project water supply to offset the effects of operational curtailments under the EWA program so that deliveries will not be affected. The EWA will acquire only the amount of water that is needed, and may not purchase all of the water that is offered in a given year. If the program is extended to include future years, then the agencies will determine the appropriate size and composition of the EWA, and the appropriate environmental review.

Tier 3 consists of the ability of the CALFED agencies to make additional water available as needed to meet Endangered Species Act requirements beyond those quantities specified in Tier 1 and Tier 2. Tier 3 has been designed to be used when Tier 1 and Tier 2 assets are insufficient or exhausted and the Management Agencies determine that jeopardy to the survival and recovery of an endangered or threatened species will occur unless additional measures are taken. The appropriate Management Agencies will make the determination that the proposed project operations would jeopardize the continued existence of the effected species. Under these circumstances, the EWA would purchase additional quantities of water to support operational curtailments necessary to avoid jeopardizing the species at risk.

Location of Project

The project is located within the state of California and may include any and all parties who meet criteria defined by the Project Agencies and Managing Agencies for meeting the objectives of the EWA

Alternative Measures

The ROD for the CALFED Bay Delta Program described broad actions to be taken as part of a long-term plan to fix the problems in the Delta: ecosystem quality, water quality, supply reliability, and levee system integrity. As described above, the EWA is one element of the long-term plan to which the signatory agencies have committed. This EIR/EIS will focus on a project specific evaluation of alternative strategies for meeting the objectives of the EWA, including purchasing variable quantities of water, banking, borrowing, transferring water, and using functional equivalent water assets to achieve the objectives of the EWA.

Probable Environmental Effects

It is generally recognized that certain types of water transfers can result in adverse, as well as beneficial impacts on the environment and certain local economic conditions. For example, fallowing may reduce the quantity of agricultural production in the source area and thereby affect the local economy, while groundwater transfers or transfers of surface water with groundwater replacement may result in lower groundwater levels, lower groundwater quality, and higher energy costs. The extent of these impacts will depend on

the amount and type of such transfers in a given area. This environmental document will evaluate potential project-specific and cumulative impacts, and identify and incorporate mitigation measures when impacts are identified.

Scoping Meetings

A series of public scoping meetings were held in late summer 2001 to solicit public input on alternatives, concerns, and issues to be addressed in the EIS/EIR. No additional scoping meetings are planned.

Written Comments

Within 30 days after receiving the Notice of Preparation, each Responsible Agency shall provide the Lead Agency with specific detail about the scope, significant environmental issues, reasonable alternatives, and mitigation measures related to the Responsible Agency's area of statutory responsibility that will need to be explored in the draft EIR.

Comments from individual respondents, including names and home addresses of respondents, will be made available for public review. Individual respondents may request that their home address be withheld from public disclosure, which we will honor to the extent allowable by law. There also may be circumstances in which we would withhold a respondent's identity from public disclosure, as allowable by law. If you wish us to withhold your name and/or address, you must state this prominently at the beginning of your comment. We will make all submissions from organizations or businesses, and from individuals identifying themselves as representatives or officials of organizations or businesses, available for public disclosure in their entirety.

Written comments on the scope of the EIR/EIS should be sent to Ms. Delores Brown, Department of Water Resources, 3251 S Street, Sacramento, CA 95816 or Mr. Dave Robinson, Bureau of Reclamation, 2800 Cottage Way, MP-700, Sacramento, CA 95825.

Barbara McDonnell
Chief, Environmental Services Office

Date May 28, 2002

DEPARTMENT OF THE INTERIOR

Bureau of Reclamation

Environmental Water Account, San Francisco Bay/Sacramento-San Joaquin Delta, CA

AGENCY: Bureau of Reclamation/ California Department of Water Resources, Interior.

ACTION: Notice of intent to prepare an environmental impact statement/ environmental impact report (EIS/EIR).

SUMMARY: Pursuant to the National Environmental Policy Act (NEPA) and the California Environmental Quality Act (CEQA), the Bureau of Reclamation (Reclamation) and the California Department of Water Resources (DWR) intend to prepare an EIS/EIR for implementing the Environmental Water Account (EWA) as described in the Programmatic Record of Decision for the CALFED Bay-Delta Program.

The EWA has been established to provide water for the protection and recovery of fish beyond water available through existing regulatory actions related to State Water Project/Central Valley Project operations. The EWA is a cooperative management program whose purpose is to provide protection to the fish of the Bay-Delta estuary through environmentally beneficial changes in project operations at no uncompensated water cost to the projects' water users. This approach to fish protection requires the acquisition of alternative sources of project water supply, called the "EWA assets," which will be used to augment streamflows, Delta outflows, to modify exports to provide fishery benefits, and to replace the regular project water supply interrupted by the changes to project operations. The replacement water will compensate for reductions in deliveries relative to existing facilities, project operations and the regulatory baseline that result from EWA actions.

Reclamation will be the lead federal agency; the U.S. Fish and Wildlife Service and National Marine Fisheries Service will be cooperating agencies for the EIS/EIR in accordance with NEPA. DWR will be the lead state agency; the Department of Fish and Game will be a responsible agency for the EIS/EIR in accordance with CEQA. A draft EIS/EIR is expected to be available in December 2001.

DATES: A series of public scoping meetings will be held to solicit public input on alternatives, concerns, and issues to be addressed in the EIS/EIR as follows:

- Thursday, July 19, 10–12 noon, Sacramento, CA.
- Thursday, July 19, 7–9 p.m., Chico, CA.
- Monday, July 23, 7–9 p.m., Oakland, CA.
- Tuesday, July 24, 7–9 p.m., Tracy, CA.
- Wednesday, July 25, 7–9 p.m., Bakersfield, CA.
- Thursday, July 26, 7–9 p.m., Los Angeles, CA.

Written comments on the scope of the EIS/EIR may be mailed to Reclamation at the address below by August 20, 2001.

ADDRESSES: The meeting locations are:

- Sacramento at Best Western Expo Inn, 1413 Howe Avenue.
- Chico at Chico Area Recreation District Community Center, 545 Vallambrosa.
- Oakland at the Federal Building, Room H, 5th Floor, North Tower.
- Tracy at the VFW Hall, 430 West Grant Line Road.
- Bakersfield at the Double Tree Inn, 3100 Camino Del Rio Court, Sierra Room.
- Los Angeles at the Los Angeles Convention Center, 1201 South Figueroa Street, Room 513.

Written comments on the scope of the EIS/EIR should be sent to Ms. Michelle Light, Bureau of Reclamation, 2800 Cottage Way, MP–700, Sacramento, CA 95825.

FOR FURTHER INFORMATION CONTACT: Ms. Light at the above address or by telephone at 916–978–5060 or TDD 1–800–735–2922; or Ms. Delores Brown, Department of Water Resources, 3251 S Street, Sacramento, CA 95816 or by telephone at 916–227–2407.

SUPPLEMENTARY INFORMATION:

Background

The CALFED Bay Delta Program is a long-term comprehensive plan to restore ecological health and improve water management for beneficial uses in the San Francisco Bay/Sacramento-San Joaquin Delta (Bay-Delta) estuary system. The agencies that signed the Record of Decision/Notice of Determination (ROD) for the Final Programmatic Environmental Impact Statement/Environmental Impact Report on August 28, 2000, committed to implement the CALFED Bay Delta Program. The Environmental Water Account (EWA) is one component of the long-term comprehensive plan adopted in the CALFED Bay-Delta Program ROD.

To achieve the program purpose, the long-term plan addresses problems of the Bay-Delta system within each of four resource categories: ecosystem quality, water quality, water supply reliability, and levee system integrity. CALFED agencies identified a need in the ROD for additional fisheries protection measures above and beyond the existing baseline regulatory measures to speed recovery of listed fish species. The establishment of the EWA was a key component of this additional protection.

The EWA is a cooperative management program involving five CALFED agencies that have responsibility for implementing the EWA. The three management agencies, the U.S. Fish and Wildlife Service (USFWS), the National Marine Fisheries Service (NMFS), and the California Department of Fish and Game (DFG), have primary responsibility for determining how to manage the EWA assets to benefit long-term survival of fish species, including those listed under the State and Federal Endangered Species Acts. The two Project Agencies are Reclamation and the Department. The Project Agencies will cooperate with the Management Agencies in administering the EWA, including banking, borrowing, transferring, selling, making operational changes, and arranging for the conveyance of EWA assets.

Current Activities

Following the signing of the ROD in August of 2000, the California Department of Water Resources undertook the initial required acquisitions and one-year transfers. As of June 2001, 294,000 acre-feet had been acquired of which 281,000 acre-feet was used to protect threatened and endangered fish species. A critique and scientific review of the first year of EWA implementation will be conducted this summer, and the results will be used to help formulate strategies for managing the EWA in subsequent years.

Alternative Measures

The ROD for the CALFED Bay Delta Program described broad actions to be taken as part of a long-term plan to fix the problems in the Delta: ecosystem, water quality, water supply reliability and levee stability. As described above, the EWA is one element of the long-term plan to which the signatory agencies have committed. This EIS/EIR will focus on a project specific evaluation of the EWA including alternative strategies for banking, borrowing, transferring, and using water assets to achieve the EWA.

Our practice is to make comments, including names and home addresses of respondents, available for public review. Individual respondents may request that we withhold their home address from public disclosure, which

we will honor to the extent allowable by law. There also may be circumstances in which we would withhold a respondent's identity from public disclosure, as allowable by law. If you wish us to withhold your name and/or address, you must state this prominently at the beginning of your comment. We will make all submissions from organizations or businesses, and from individuals identifying themselves as representatives or officials of organizations or businesses, available for public disclosure in their entirety.

Dated: June 22, 2001.

Laura Allen,

Acting Regional Environmental Officer.

[FR Doc. 01–16928 Filed 7–5–01; 8:45 am]

BILLING CODE 4310–MN–P

INTERNATIONAL TRADE COMMISSION

[Investigations Nos. 731–TA–951 and 952 (Preliminary)]

Blast Furnace Coke From China and Japan

AGENCY: International Trade Commission.

ACTION: Institution of antidumping investigations and scheduling of preliminary phase investigations.

SUMMARY: The Commission hereby gives notice of the institution of investigations and commencement of preliminary phase antidumping investigations Nos. 731–TA–951 and 952 (Preliminary) under section 733(a) of tne Tariff Act of 1930 (19 U.S.C. 1673b(a)) (the Act) to determine whether there is a reasonable indication that an industry in the United States is materially injured or threatened with material injury, or the establishment of an industry in the United States is materially retarded, by reason of imports from China and Japan of blast furnace coke provided for in statistical reporting numbers 2704.00.0025 and 2704.00.0050 of the Harmonized Tariff Schedule of the United States, that are alleged to be sold in the United States at less than fair value. Unless the Department of Commerce extends the time for initiation pursuant to section 732(c)(1)(B) of the Act (19 U.S.C. 1673a(c)(1)(B)), the Commission must reach a preliminary determination in antidumping investigations in 45 days, or in this case by August 13, 2001. The Commission's views are due at Commerce within five business days thereafter, or by August 20, 2001.

For further information concerning the conduct of these investigations and rules of general application, consult the Commission's Rules of Practice and Procedure, part 201, subparts A through E (19 CFR part 201), and part 207, subparts A and B (19 CFR part 207).

EFFECTIVE DATE: June 29, 2001.

FOR FURTHER INFORMATION CONTACT: Fred Fischer (phone: 202–205–3179; e-mail: *ffischer@usitc.gov*), Office of Investigations, U.S. International Trade Commission, 500 E Street SW, Washington, DC 20436. Hearing-impaired persons can obtain information on this matter by contacting the Commission's TDD terminal on 202–205–1810. Persons with mobility impairments who will need special assistance in gaining access to the Commission should contact the Office of the Secretary at 202–205–2000. General information concerning the Commission may also be obtained by accessing its internet server (*http://www.usitc.gov*). The public record for these investigations may be viewed on the Commission's electronic docket (EDIS–ON–LINE) at *http://dockets.usitc.gov/eol/public.*

SUPPLEMENTARY INFORMATION:

Background.—These investigations are being instituted in response to a petition filed on June 29, 2001, by (1) the Committee for Fair Coke Trade and its member producers: Acme Steel Co., Chicago, IL; DTE Energy Services Inc., Ann Arbor, MI; Koppers Industries, Inc., Pittsburgh, PA; and Shenango Inc., Pittsburgh, PA; and (2) the United Steelworkers of America, AFL–CIO, Pittsburgh, PA.

Participation in the investigations and public service list.—Persons (other than petitioners) wishing to participate in the investigations as parties must file an entry of appearance with the Secretary to the Commission, as provided in sections 201.11 and 207.10 of the Commission's rules, not later than seven days after publication of this notice in the **Federal Register**. Industrial users and (if the merchandise under investigation is sold at the retail level) representative consumer organizations have the right to appear as parties in Commission antidumping investigations. The Secretary will prepare a public service list containing the names and addresses of all persons, or their representatives, who are parties to these investigations upon the expiration of the period for filing entries of appearance.

Limited disclosure of business proprietary information (BPI) under an administrative protective order (APO) and BPI service list.—Pursuant to section 207.7(a) of the Commission's rules, the Secretary will make BPI gathered in these investigations available to authorized applicants representing interested parties (as defined in 19 U.S.C. 1677(9)) who are parties to the investigations under the APO issued in the investigations, provided that the application is made not later than seven days after the publication of this notice in the **Federal Register**. A separate service list will be maintained by the Secretary for those parties authorized to receive BPI under the APO.

Conference.—The Commission's Director of Operations has scheduled a conference in connection with these investigations for 9:30 a.m. on July 20, 2001, at the U.S. International Trade Commission Building, 500 E Street SW., Washington, DC. Parties wishing to participate in the conference should contact Fred Fischer (phone: 202–205–3179; e-mail: *ffischer@usitc.gov*) not later than July 16, 2001, to arrange for their appearance. Parties in support of the imposition of antidumping duties in these investigations and parties in opposition to the imposition of such duties will each be collectively allocated one hour within which to make an oral presentation at the conference. A nonparty who has testimony that may aid the Commission's deliberations may request permission to present a short statement at the conference.

Written submissions.—As provided in sections 201.8 and 207.15 of the Commission's rules, any person may submit to the Commission on or before July 25, 2001, a written brief containing information and arguments pertinent to the subject matter of the investigations. Parties may file written testimony in connection with their presentation at the conference no later than three days before the conference. If briefs or written testimony contain BPI, they must conform with the requirements of sections 201.6, 207.3, and 207.7 of the Commission's rules. The Commission's rules do not authorize filing of submissions with the Secretary by facsimile or electronic means.

In accordance with sections 201.16(c) and 207.3 of the rules, each document filed by a party to the investigations must be served on all other parties to the investigations (as identified by either the public or BPI service list), and a certificate of service must be timely filed. The Secretary will not accept a document for filing without a certificate of service.

Authority: These investigations are being conducted under authority of title VII of the Tariff Act of 1930; this notice is published pursuant to section 207.12 of the Commission's rules.

ENVIRONMENTAL WATER ACCOUNT

DRAFT ENVIRONMENTAL IMPACT STATEMENT/
ENVIRONMENTAL IMPACT REPORT

APPENDIX G

Water Quality Technical Appendix

Appendix G
Water Quality Technical Appendix

The Water Quality Technical Appendix supplements Chapter 5 Water Quality in the Environmental Water Account (EWA) Draft EIS/EIR. The sections below provide detailed information about constituents of concern listed in the Clean Water Act and beneficial uses of California waters defined in the California Water Code. The following sections discuss water quality in the San Joaquin-Sacramento Delta, and general water quality characteristics of reservoirs. The appendix ends with a detailed description of water quality effects in the Upstream from the Delta Region under the Flexible Purchase Alternative.

1.1 Constituents of Concern of 303(d) Listed Waterbodies

1.1.1 Cadmium

Cadmium is an element that occurs naturally in the earth's crust. Pure cadmium is a soft, silver-white metal; however cadmium is not usually found in the environment as a metal. It is usually found as a mineral combined with other elements such as oxygen (cadmium oxide), chlorine (cadmium chloride), or sulfur (cadmium sulfate, cadmium sulfide). These compounds are solids that may dissolve in water but do not evaporate or disappear from the environment. All soils and rocks, including coal and mineral fertilizers, have some cadmium in them. Cadmium is often found as part of small particles present in air. Most cadmium used in this country is extracted during the production of other metals such as zinc, lead, or copper. Cadmium has many uses in industry and consumer products, mainly batteries, pigments, metal coatings, and plastics (ATSDR 1999a).

Cadmium enters air from mining, industry, and burning coal and household wastes. Particles can travel long distances in the air before falling to the ground or water. Cadmium can also enter water and soil from waste disposal and spills or leaks at hazardous waste sites. Fish, plants, and animals take up cadmium from the environment. Cadmium stays in the body a very long time and can build up from many years of exposure to low levels. Exposure to cadmium can occur through breathing contaminated workplace air (battery manufacturing, metal soldering or welding); eating foods containing it; low levels in all foods (highest in shellfish, liver, and kidney meats); breathing cadmium in cigarette smoke (doubles the average daily intake); drinking contaminated water; and breathing contaminated air near the burning of fossil fuels or municipal waste.

Breathing high levels of cadmium severely damages the lungs and can cause death. Eating food or drinking water with very high levels severely irritates the stomach, leading to vomiting and diarrhea. Long-term exposure to lower levels of cadmium in air, food, or water leads to a buildup of cadmium in the kidneys and possible kidney disease. Other long-term effects are lung damage and fragile bones. Animals given

cadmium in food or water had high blood pressure, iron-poor blood, liver disease, and nerve or brain damage. Federal agencies have made several recommendations to protect human health, including:

- The EPA has set a limit of 5 parts of cadmium per billion parts of drinking water (5 ppb). The EPA doesn't allow cadmium in pesticides (ATSDR 1999a).
- The FDA limits the amount of cadmium in food colors to 15 parts per million (15 ppm) (ATSDR 1999a).
- The OSHA limits workplace air to 100 micrograms cadmium per cubic meter (100 $\mu g/m^3$) as cadmium fumes and 200 µg cadmium/m^3 as cadmium dust (ATSDR 1999a).

1.1.2 Chlorpyrifos

Chlorpyrifos is an insecticide that is a white crystal-like solid with a strong odor. It does not mix well with water, so it is usually mixed with oily liquids before it is applied to crops or animals. It may also be applied to crops in a capsule form. Chlorpyrifos has been widely used in homes and on farms. In the home, it is used to control cockroaches, fleas, and termites; it is also used in some pet flea and tick collars. On the farm, it is used to control ticks on cattle and as a spray to control crop pests (ATSDR 1997).

Chlorpyrifos enters the environment through direct application to crops, lawns, houses and other buildings. It may also enter the environment through volatilization, spills, and the disposal of chlorpyrifos waste. Chlorpyrifos sticks tightly to soil particles. As it does not mix well with water, it rarely enters local water systems. Once in the environment, it is broken down by sunlight, bacteria, or other chemical processes. Exposure to chlorpyrifos occurs when using it to control household pests such as termites, fleas or cockroaches; breathing air outside of homes or other buildings where chlorpyrifos was applied to the ground around the foundation to control termites; breathing air in a field where chlorpyrifos was sprayed on to crops; and, touching soil or crops in a field where it was sprayed or touching freshly sprayed areas in a house.

Breathing the air in an area in which chlorpyrifos has recently been sprayed may produce a variety of effects on the nervous system including headaches, blurred vision, watering of the eyes (called lacrimation), excessive salivation, runny nose, dizziness, confusion, muscle weakness or tremors, nausea, diarrhea, and sudden changes in heart rate. The effect depends on the amount in the air and length of time exposed. Federal agencies have made several recommendations to protect human health, including:

- The EPA requires that spills or accidental releases into the environment of 1 pound or more of chlorpyrifos be reported to the EPA (ATSDR 1997).

- The EPA also recommends that children not drink water with chlorpyrifos levels greater than 0.03 milligrams per liter (mg/L) of water (0.03 mg/L) for periods of 1–10 days (ATSDR 1997).

- The FDA has set tolerances for chlorpyrifos for agricultural products ranging from 0.05 to 15 parts chlorpyrifos per million parts of food (0.05–15 ppm) (ATSDR 1997).

1.1.3 Copper

Copper is a reddish metal that occurs naturally in rocks, soil, water, and air; and, also occurs naturally in plants and animals. Metallic copper can be easily molded or shaped. Metallic copper can be found in the U.S. penny, electrical wiring, and some water pipes. Metallic copper is also found in mixtures (called alloys) with other metals such as brass and bronze. Copper is also found as part of other compounds forming salts. Copper salts occur naturally, but are also manufactured. The most common copper salt is copper sulfate. Most copper compounds are blue-green in color. Copper compounds are commonly used in agriculture to treat plant diseases like mildew, for water treatment and, as preservatives for wood, leather, and fabrics (ATSDR 2002h).

Copper can enter the environment from the mining of copper and other metals and from factories that make or use metallic copper or copper compounds. It can also enter the environment through domestic waste water, combustion of fossil fuels and wastes, wood production, phosphate fertilizer production, and natural sources (e.g., windblown dust from soils, volcanoes, decaying vegetation, forest fires, and sea spray). Copper in soil strongly attaches to organic material and minerals, but does not break down in the environment. Copper that dissolves in water becomes rapidly bound to particles suspended in the water. Copper does not typically enter groundwater. Copper carried by particles emitted from smelters and ore processing plants is carried back to the ground by gravity or in rain or snow. Exposure to copper occurs through breathing air, drinking water, eating food, and by skin contact with soil, water, or other copper-containing substances. Plants and animals can take up some copper in the environment.

Copper is essential for good health, but high amounts can be harmful. Long-term exposure to copper dust can irritate the nose, mouth, and eyes, and cause headaches, dizziness, nausea, and diarrhea. Drinking water with higher than normal levels of copper may cause vomiting, diarrhea, stomach cramps, and nausea. Ingestion of large amounts of copper can cause liver and kidney damage and even death. Federal agencies made several recommendations to protect human health, including:

- The EPA has determined that drinking water should not contain more than 1.3 milligrams of copper per liter of water (1.3 mg/L) (ATSDR 2002h).

- The OSHA has set a limit of 0.1 mg per cubic meter (0.1 mg/m^3) of copper fumes (vapor generated from heating copper) and 1 mg/m^3 of copper dusts (fine metallic copper particles) and mists (aerosol of soluble copper) in workroom air during an 8-hour work shift, 40-hour workweek (ATSDR 2002h).

- The Food and Nutrition Board of the Institute of Medicine recommends dietary allowances (RDAs) of 340 micrograms (340 µ g) of copper per day for children aged 1-3 years, 440 g/day for children aged 4-8 years, 700 µg/day for children aged 9-13 years, 890 µg/day for children aged 14-18 years, and 900 g/day for adults (ATSDR 2002h).

1.1.4 DDT

- DDT (dichlorodiphenyltrichloroethane) is a pesticide once widely used to control insects in agriculture and insects that carry diseases such as malaria. DDT is a white, crystalline solid with no odor or taste. Its use in the U.S. was banned in 1972 because of damage to wildlife, but is still used in some countries. DDE (dichlorodiphenyldichloroethylene) and DDD (dichlorodiphenyldichloroethane) are chemicals similar to DDT that contaminate commercial DDT preparations (ATSDR 2002i).

- DDT entered the environment when it was used as a pesticide; it still enters the environment due to current use in other countries. DDT sticks strongly to soil; most DDT in soil is broken down slowly to DDE and DDD by microorganisms. Half the DDT in soil will break down in 2-15 years, depending on the type of soil. Only a small amount will go through the soil into groundwater; DDT does not dissolve easily in water. DDT, and especially DDE, build up in plants and in fatty tissues of fish, birds, and other animals. Exposure to DDT occurs through eating contaminated foods, such as root and leafy vegetable, fatty meat, fish, and poultry, but levels are very low; eating contaminated imported foods from countries that still allow the use of DDT to control pests; breathing contaminated air or drinking contaminated water near waste sites and landfills that may contain higher levels of these chemicals; infants fed on breast milk from mothers who have been exposed; and breathing or swallowing soil particles near waste sites or landfills that contain these chemicals.

- DDT affects the nervous system. People who accidentally swallowed large amounts of DDT became excitable and had tremors and seizures. These effects went away after the exposure stopped. No effects were seen in people who took small daily doses of DDT by capsule for 18 months. A study in humans showed that women who had high amounts of a form of DDE in their breast milk were unable to breast feed their babies for as long as women who had little DDE in the breast milk. Another study in humans showed that women who had high amounts of DDE in breast milk had an increased chance of having premature babies. In animals, short-term exposure to large amounts of DDT in food affected the nervous system, while long-term exposure to smaller amounts affected the

liver. Short-term oral exposure to small amounts of DDT or its breakdown products may also have harmful effects on animal reproduction. Federal agencies have made several recommendations to protect human health, including:

- The OSHA sets a limit of 1 milligram of DDT per cubic meter of air (1 mg/m^3) in the workplace for an 8-hour shift, 40-hour workweek (ATSDR 2002i).

- The FDA has set limits for DDT, DDE, and DDD in foodstuff at or above which the agency will take legal action to remove the products from the market (ATSDR 2002i).

1.1.5 Diazinon

Diazinon is the common name of an organophosphorus insecticide used to control pest insects in soil, on ornamental plants, and on fruit and vegetable field crops. It is also used to control household pests such as flies, fleas, and cockroaches. This chemical is manufactured and does not occur naturally in the environment. The pure chemical is a colorless and practically odorless oil. Most of the diazinon used is in liquid form, but it is possible to be exposed to the chemical in a solid form. Diazinon does not burn easily and does not dissolve easily in water (ATSDR. 1996a).

Most environmental diazinon contamination comes from agricultural and household application to control insects. Diazinon may also enter the environment during the manufacturing process. It is often sprayed on crops and plants, so small particles of the chemical may be carried away from the field or yard before falling to the ground. After diazinon has been applied, it may be present in the soil, surface waters, and on the surface of the plants. Diazinon on soil and plant surfaces may be washed into surface waters by rain. In the environment, diazinon is rapidly broken down into a variety of other chemicals. It can move through the soil and contaminate ground water. Diazinon is not likely to build up to high or dangerous levels in animal or plant foods. Exposure to diazinon occurs through contact with contaminated soils or contaminated runoff water or groundwater. People who work in the manufacture and professional application of diazinon have the most significant exposure to this insecticide.

Most cases of unintentional diazinon poisoning in people have resulted from short exposures to very high concentrations of the material. Diazinon affects the nervous system. Some mild symptoms include headache, dizziness, weakness, feelings of anxiety, constriction of the pupils of the eye, and not being able to see clearly. More severe symptoms include nausea and vomiting, abdominal cramps, slow pulse, diarrhea, pinpoint pupils, difficulty breathing, and coma. The EPA has developed 1- and 10-day health advisories (maximum recommended drinking water concentrations) for adults and children of 20 micrograms per liter of water (20 µg/L) (ATSDR 1996a).

1.1.6 Dioxin Compounds

The chlorinated dibenzo-p-dioxins (CDDs) are a class of compounds that are loosely referred to as dioxins. There are 75 possible dioxins. One of these compounds is called 2,3,7,8-TCDD. It is one of the most toxic of the CDDs and is the one most studied. In the pure form, CDDs are crystals or colorless solids. CDDs enter the environment as mixtures containing a number of individual components. 2,3,7,8-TCDD is odorless and the odors of the other CDDs are not known. CDDs are not intentionally manufactured by industry except for research purposes or as by-products. They (mainly 2,3,7,8-TCDD) may be formed during the chlorine bleaching process at pulp and paper mills. CDDs are also formed during chlorination by waste and drinking water treatment plants. They can occur as contaminants in the manufacture of certain organic chemicals. CDDs are released into the air in emissions from municipal solid waste and industrial incinerators (ATSDR 1998).

When released into the air, some CDDs may be transported long distances, even around the globe. When released in waste waters, some CDDs are broken down by sunlight, some evaporate to air, but most attach to soil and settle to the bottom sediment in water. CDD concentrations may build up in the food chain, resulting in measurable levels in animals. Eating food, primarily meat, dairy products, and fish, makes up more than 90% of the intake of CDDs for the general population. Exposure could also occur by breathing low levels in air and drinking low levels in water; skin contact with certain pesticides and herbicides; living near an uncontrolled hazardous waste site containing CDDs or incinerators releasing CDDs; and working in industries involved in producing certain pesticides containing CDDs as impurities, working at paper and pulp mills, or operating incinerators.

The most noted health effect in people exposed to large amounts of 2,3,7,8-TCDD is chloracne. Chloracne is a severe skin disease with acne-like lesions that occur mainly on the face and upper body. Other skin effects noted in people exposed to high doses of 2,3,7,8-TCDD include skin rashes, discoloration, and excessive body hair. Changes in blood and urine that may indicate liver damage also are seen in people. Exposure to high concentrations of CDDs may induce long-term alterations in glucose metabolism and subtle changes in hormonal levels. In certain animal species, 2,3,7,8-TCDD is especially harmful and can cause death after a single exposure. Exposure to lower levels can cause a variety of effects in animals, such as weight loss, liver damage, and disruption of the endocrine system. In many species of animals, 2,3,7,8-TCDD weakens the immune system and causes a decrease in the system's ability to fight bacteria and viruses. In other animal studies, exposure to 2,3,7,8-TCDD has caused reproductive damage and birth defects. The EPA has set a limit of 0.00003 micrograms of 2,3,7,8-TCDD per liter of drinking water (0.00003 µg/L) (ATSDR 1998). Discharges, spills, or accidental releases of 1 pound or more of 2,3,7,8-TCDD must be reported to EPA. The FDA recommends against eating fish and shellfish with levels of 2,3,7,8-TCDD greater than 50 parts per trillion (50 ppt) (ATSDR 1998).

1.1.7 Electrical Conductivity

Conductivity is the ability of water to conduct an electrical current. Dissolved ions in the water are conductors. The major positively charged ions are sodium, (Na^{+}) calcium (Ca^{+2}), potassium (K^{+}) and magnesium (Mg^{+2}). The major negatively charged ions are chloride (Cl^{-}), sulfate (SO_4^{-2}), carbonate (CO_3^{-2}), and bicarbonate (HCO_3^{-}). Nitrates (NO_3^{-2}) and phosphates (PO_4^{-3}) are minor contributors to conductivity, although very important biologically.

Salinity is a measure of the amount of salts in the water. Because dissolved ions increase salinity as well as conductivity, the two measures are related. Conductivity can affect the quality of water used for irrigation or drinking. Most aquatic biota tolerate a range of conductivity. However, the ionic composition of the water can be critical. For example, cladocerans (water fleas) are far more sensitive to potassium chloride than sodium chloride at the same concentration. Conductivity will vary with water source: groundwater, water drained from agricultural fields, municipal waste water, rainfall. Therefore, conductivity can indicate groundwater seepage or a sewage leak.

Conductivity is measured by an electronic probe which applies voltage between two electrodes. The drop in voltage is used to measure the resistance of the water, which is then converted to conductivity. Conductivity is the inverse of resistance and is measured in the amount of conductance over a certain distance. The units are mhos/cm, where mhos are the reciprocal of ohms. Salinity can be measured using a hydrometer or a refractometer. The hydrometer measures specific gravity, which can then be converted to salinity. The refractometer measures the ability of the water to refract light. Scientists also measure salinity by determining the amount of chlorine in seawater. Salinity is measured in grams/liter (g/l) or parts per thousand (ppt) in sea water.

In fresher waters, total dissolved solids is often measured instead of salinity. It is measured by filtering a sample, drying the water that has been filtered, and then weighing the remaining solids. TDS is the solid material left in the water after it has been dried and evaporated. The units of TDS are milligrams/liter (mg/l) or parts per million (ppm).

Several factors affect electrical conductivity in the water. Soil and rocks release ions into the waters that flow through or over them. The geology of a certain area will determine the amount and type of ions. The salinity and conductivity of coastal rivers is influenced by tides. Sea spray can carry salts into the air, which then fall back into the rivers with rainfall. The flow of rivers into estuaries can greatly affect salinity as well as the location of the estuarine mixing zone.

The water quality objectives for conductivity vary from region to region. Water quality objectives are included in the RWQCB Basin Plans. In some cases, there are no objectives for conductivity, but there are for total dissolved solids (TDS). Conductivity can be estimated from TDS values and vice versa.

1.1.8 Exotic Species

A species is a group of organisms all of which have a high degree of physical and genetic similarity, generally interbreed only among themselves, and show persistent differences from members of allied groups of organisms. An exotic species is defined as any species that is not native to a particular ecosystem, including its seeds, eggs, spores, or other biological material capable of propagating that species. Synonyms for exotic species include non-native species, nonindigenous species, and alien species. When an exotic species is introduced into a new ecosystem, there is potential for significant disruption of the balance among existing native and naturalized species, especially if the exotic species competes with native species for resources and no predators are able to control the population of the exotic species. When an exotic species does or is likely to cause economic or environmental harm, or harm to human health, it is known as an "invasive species." Yet another synonym for such an organism occurring in or near waters is "aquatic nuisance species," or ANS, as defined in the National Invasive Species Act (NISA). Competition with and predation by invasive species affects 49 percent of endangered or threatened species in the United States (Wilcove et al. 1998). About 42 percent of the species listed as endangered or threatened under the Endangered Species Act of 1973 are at risk primarily because of exotic species (Pimentel et al. 1999).

Although the effects of many exotic species introductions remain unmeasured, it is clear that some "invasive" exotic species, or ANS, are having significant economic and ecological impacts as well as human-health consequences. Today, the main method by which exotic species are transported between biogeographic regions of the Earth is moving species via ships on their exteriors or in their ballast water (SERC 2000). Ballast-mediated introductions such as the zebra mussel in the U.S. Great Lakes and toxic dinoflagellates in Australia have had tremendous ecological and economic impacts. Water-borne diseases such as cholera and hepatitis can be transported with ballast water (Knight 1999; Harvell et al. 1985). While the ship vector is probably the greatest source, there are other sources of exotic species to aquatic ecosystems, which include the aquaculture and baitfish industries, dumping of aquariums into surface waters, and intentional introductions.

1.1.9 Furan Compounds

The polychlorinated dibenzofurans (PCDFs) are a group of 135 halogenated uicyclic aromatic hydrocarbons with many structural, distribution, and toxicity similarities to the dioxins (polychlorinated dibenzodioxins, PCDDs). Very little is known about the individual furans because they typically occur as mixtures of different forms. For this reason, the sources, environmental fates, and health effects of the PCDFs will be discussed as a group, with mention of individual furans when appropriate.

PCDFs are not intentionally produced for any commercial purposes. PCDF contamination of products or processes has not caused the banning or restriction of use in the U.S. Just like the PCDDs, PCDFs are unwanted trace impurities of PCBs, chlorinated phenols such as hexachlorobenzene or pentachlorophenol, and phenoxy

herbicides. The production of many of these compounds has been restricted or banned (e.g., PCBs), but products containing them may still be in use (e.g., electrical transformers). Example concentrations are listed below:

- Phenoxy herbicides had 0.008-0.15 mg/kg PCDFs (Rappe et al. 1978 1979; Ah-ling et al. 1977).
- Pentachlorophenol has contained 59.8-790 mg/kg PCDFs (Rappe et al. 1979).
- Hexachiorobenzene was found to contain 0.35 to 58.3 mg/kg PCDFs (Villanueva et al. 1974).
- PCDF contaminants in polychiorinated biphenyls (PCBs) have been measured at levels of 0.8 to 13.6 mg/kg (CNRC 1978).
- Incineration of municipal and industrial wastes at too low a temperature (~800^{o} C) can produce PCDFs, which can be released to the environment either in flue gas or adsorbed to fly ash (U.S. EPA 1986).

The compound 2,3,7,8 TCDF is the only PCDF for which a number of physical and chemical properties have been determined. Based on these properties, and its structural similarity to the dioxin 2,3,7,8, TCDD, 2,3,7,8 TCDF is likely to be only slightly soluble in water and strongly absorb to soil. It also has a high potential for bioaccumulation (Hansch and Leo 1981). Because 2,3,7,8 TCDF strongly sorbs to sediments, it persists in soils and aquatic systems. Some photodegradation can occur with tetra- and penta-CDFs losing chlorine atoms and forming tri-CDFs. Very little is known about the biodegradation of PCDFs, but they are probably like the dioxins and relatively resistant to biodegradation (U.S. EPA 1986b).

Human exposure to PCDFs occurred in two major incidents when PCBs (containing a mixture of PCDFs) accidentally contaminated rice oil in Japan and China. The resulting symptoms (attributed to 2,3,4,7,8 PeCDF exposure) consisted of liver disturbances, skin lesions, excessive skin pigmentation, temporary blindness, numbness of feet and hands, and weakness (Kuratsune et al. 1972; Kuratsune 1975, 1980; Urabe and Asahi 1985; Lu and Wu 1985). Studies of potential carcinogenesis in humans are still ongoing. No tests have been conducted with animals (U.S. EPA 1986b). Reproductive effects include:

- 1,2,3,4,7,8 PeCDF, 1,2,3,7,8 PeCDF and 1,2,3,4,7,8 HxCDF can cause kidney damage and cleft palate in mouse fetuses (U.S. EPA 1986b).

The four PCDFs (2,8 DCDF; 3,6 DCDF; 2,3,7,8 TCDF; and OCDF) tested for mutagenicity in bacteria had negative results (U.S. EPA 1986b). The Toxicological Effects Indices are:

- Reference Dose (RfD), 2,3,7,8 TCDF: 2x10-5 CLg/kg/day (U.S. EPA 1986b).

- Reference Dose (RfD), 2,3,4,7,8 PeCDF: 3x10-6 t.tg/kg/day (U.S. EPA 1986b).

- Oral LD50 values for 2,3,7,8 TCDF: guinea pigs, 5-10 pg/kg; mice and rats, > 6000 PgAcg; rhesus monkey, 1000 pg/kg (U.S. EPA 1986b).

1.1.10 Group A Pesticides

1.1.10.1 Aldrin and Dieldrin

Aldrin and dieldrin are insecticides with similar chemical structures. They are discussed together in this fact sheet because aldrin quickly breaks down to dieldrin in the body and in the environment.

Pure aldrin and dieldrin are white powders with a mild chemical odor. The less pure commercial powders have a tan color. Neither substance occurs naturally in the environment. From the 1950s until 1970, aldrin and dieldrin were widely used pesticides for crops like corn and cotton. Because of concerns about damage to the environment and potentially to human health, EPA banned all uses of aldrin and dieldrin in 1974, except to control termites. In 1987, EPA banned all uses (ATSDR. 2002a).

Sunlight and bacteria change aldrin to dieldrin so that dieldrin is the compound more likely to be found in the environment. They bind tightly to soil and slowly evaporate to the air. Dieldrin in soil and water breaks down very slowly. Plants take in and store aldrin and dieldrin from the soil. Aldrin also rapidly changes to dieldrin in plants and animals. Dieldrin is stored in the fat and leaves the body very slowly. Dieldrin is everywhere in the environment, but at very low levels. Exposure could occur through eating food like fish or shellfish from lakes or streams contaminated with either chemical, or contaminated root crops, dairy products, or meats. Air, surface water, or soil near waste sites may contain higher levels.

People who have ingested large amounts of aldrin or dieldrin suffered convulsions and some died. Health effects may also occur after a longer period of exposure to smaller amounts because these chemicals build up in the body. Some workers exposed to moderate levels in the air for a long time had headaches, dizziness, irritability, vomiting, and uncontrolled muscle movements. Workers removed from the source of exposure rapidly recovered from most of these effects. Animals exposed to high amounts of aldrin or dieldrin also had nervous system effects. In animals, oral exposure to lower levels for a long period also affected the liver and decreased their ability to fight infections. Federal agencies have made several recommendations to protect human health, including:

- The EPA limits the amount of aldrin and dieldrin that may be present in drinking water to 0.001 and 0.002 mg/L of water, respectively, for protection against health effects other than cancer. The EPA has determined that a maximum concentration of aldrin and dieldrin of 0.0002 mg/L in drinking water limits the lifetime risk of developing cancer from exposure to each compound to 1 in 10,000 (ATSDR 2002a).

- The OSHA sets a maximum average of 0.25 milligrams of aldrin and dieldrin per cubic meter of air (0.25 mg/m^3) in the workplace during an 8-hour shift, 40-hour workweek. NIOSH also recommends a limit of 0.25 mg/m^3 for both compounds for up to a 10-hour work day, 40-hour week (ATSDR 2002a).

- The FDA regulates the residues of aldrin and dieldrin in raw foods. The allowable range is from 0 to 0.1 ppm, depending on the type of food product (ATSDR 2002a).

1.1.10.2 Endrin

Endrin is a solid, white, almost odorless substance that was used as a pesticide to control insects, rodents, and birds. Endrin has not been produced or sold for general use in the United States since 1986. Little is known about the properties of endrin aldehyde (an impurity and breakdown product of endrin) or endrin ketone (a product of endrin when it is exposed to light) (ATSDR 2002j).

Endrin does not dissolve very well in water. It has been found in groundwater and surface water, but only at very low levels. It is more likely to cling to the bottom sediments of rivers, lakes, and other bodies of water. Endrin is generally not found in the air except when it has been applied to fields during agricultural applications. The persistence of endrin in the environment depends highly on local conditions. Some estimates indicate that endrin can stay in soil for over 10 years. Endrin may also be broken down by exposure to high temperatures or light to form primarily endrin ketone and endrin aldehyde. It is not known what happens to endrin aldehyde or endrin ketone once they are released to the environment. However, the amount of endrin broken down to endrin aldehyde or endrin ketone is very small.

Humans may be exposed to endrin in air, water, or soil if living near a hazardous waste site. Humans may be exposed by eating foods that contain endrin. Children living near hazardous waste sites could be exposed to endrin in contaminated soils if they eat dirt. Endrin levels can build up in the tissues of organisms that live in water. Human breast milk may be a route of exposure for nursing infants.

Exposure to endrin can cause various harmful effects including death and severe central nervous system (brain and spinal cord) injury. Swallowing large amounts of endrin may cause convulsions and kill in a few minutes or hours. Symptoms that may result from endrin poisoning are headaches, dizziness, nervousness, confusion, nausea, vomiting, and convulsions. No long-term health effects have been noted in workers who have been exposed to endrin by breathing or touching it. The federal government has made several recommendations to protect human health, including:

- The EPA's maximum contaminant level (MCL) for endrin in drinking water is 0.0002 milligrams per liter (0.0002 mg/L) (ATSDR 2002j).

- The OSHA has established a limit of 0.1 mg endrin per cubic meter of air (0.1 mg/m^3) for an 8-hour day in a 40-hour workweek (ATSDR 2002j).

1.1.10.3 Chlordane

Chlordane is a manufactured chemical that was used as a pesticide in the United States from 1948 to 1988. Technically, chlordane is not a single chemical, but is actually a mixture of pure chlordane mixed with many related chemicals. It does not occur naturally in the environment. It is a thick liquid whose color ranges from colorless to amber. Chlordane has a mild, irritating smell. Some of its trade names are Octachlor and Velsicol 1068. Until 1983, chlordane was used as a pesticide on crops like corn and citrus and on home lawns and gardens. Because of concern about damage to the environment and harm to human health, the EPA banned all uses of chlordane in 1983 except to control termites. In 1988, EPA banned all uses (ATSDR 2002b).

Chlordane entered the environment through its use as a pesticide on and as termite control. Chlordane sticks strongly to soil particles at the surface and is not likely to enter groundwater. It can stay in the soil for over 20 years. Most chlordane leaves soil by evaporation to the air, where it breaks down very slowly. Chlordane doesn't dissolve easily in water. It builds up in the tissues of fish, birds, and mammals. Exposure to chlordane could occur by eating crops grown in soil that contains chlordane; eating fish or shellfish caught in water that is contaminated by chlordane; breathing air or touching soil near homes treated for termites with chlordane; and by breathing air or by touching soil near waste sites or landfills.

Chlordane affects the nervous system, the digestive system, and the liver in people and animals. Headaches, irritability, confusion, weakness, vision problems, vomiting, stomach cramps, diarrhea, and jaundice have occurred in people who breathed air containing high concentrations of chlordane or accidentally swallowed small amounts of chlordane. Large amounts of chlordane taken by mouth can cause convulsions and death in people. Federal agencies have made several recommendations to protect human health, including:

- The EPA recommends that a child should not drink water with more than 60 parts of chlordane per billion parts of drinking water (60 ppb) for longer than 1 day. EPA has set a limit in drinking water of 2 ppb.

- EPA requires spills or releases of chlordane into the environment of 1 pound or more to be reported to EPA (ATSDR 2002b).

- The FDA limits the amount of chlordane and its breakdown products in most fruits and vegetables to less than 300 ppb and in animal fat and fish to less than 100 ppb (ATSDR 2002b).

- The OSHA, the NIOSH, and the American Conference of Governmental Industrial Hygienists (ACGIH) set a maximum level of 0.5 milligrams of chlordane per cubic meter (mg/m^3) in workplace air for an 8-hour workday, 40-hour workweek. These agencies have advised that eye and skin contact should be avoided because this may be a significant route of exposure (ATSDR 2002b).

1.1.10.4 Heptachlor and Heptachlor Epoxide

Heptachlor is a manufactured chemical and does not occur naturally. Pure heptachlor is a white powder that smells like camphor (mothballs). The less pure grade is tan. Trade names include Heptagran®, Basaklor®, Drinox®, Soleptax®, Termide®, and Velsicol 104®. Heptachlor was used extensively in the past for killing insects in homes, buildings, and on food crops, especially corn. Use slowed in the 1970s and stopped in 1988. Heptachlor epoxide is also a white powder and is a breakdown product of heptachlor. The epoxide is more likely to be found in the environment than heptachlor (ATSDR 2002d).

Heptachlor doesn't dissolve easily in water; heptachlor epoxide dissolves more easily. Each form sticks strongly to soil particles and evaporates slowly to air. Heptachlor epoxide can stay in the soil and water for many years. Animals change heptachlor to the epoxide. Plants can take up heptachlor from the soil. Levels build up in the tissues of fish and cattle.

Heptachlor and Heptachlor Epoxide exposure may occur by eating crops grown in soil that contains heptachlor and by eating fish, dairy products, and fatty meats from animals exposed to heptachlor in their food. Humans can also be exposed by breathing air, drinking water, or experiencing skin contact with soil near waste sites or landfills. Breast milk (from mothers who had high exposures) can also transmit Heptachlor and Heptachlor Epoxide.

Heptachlor and heptachlor epoxide are clearly toxic to humans and animals and can damage the nervous system. There are some human data on brief exposures to high levels. A few reports showed that people who accidentally swallowed pesticides containing heptachlor, or who spilled pesticides on their clothes became dizzy, confused, or had convulsions. The Federal government has made several recommendations to protect human health, including:

- The EPA banned the sale of all heptachlor products and restricted the use of heptachlor to the control of fire ants in power transformers. EPA recommends a maximum of 2.78 parts of heptachlor and heptachlor epoxide per trillion parts of drinking water or seafood (2.78 ppt) to eat each day. For longer exposures, a child should not drink water with greater than 5,000 ppt heptachlor or 150 ppt heptachlor epoxide. Quantities greater than 1 pound of heptachlor or heptachlor epoxide that enter the environment must immediately be reported to the National Response Center (ATSDR 2002d).

- The FDA limits the amount of heptachlor and heptachlor epoxide on raw food crops and on edible seafood to 0-10 parts per billion (ppb), depending on the type of food product. The limit on edible seafood is 300 ppb, and for the fat of food-producing animals is 200 ppb (ATSDR 2002d).

- The American Conference of Governmental Industrial Hygienists (ACGIH) and the OSHA recommend a maximum in workplace air over an 8-hour workday for a

40-hour workweek of 0.5 milligrams of heptachlor per cubic meter (0.5 mg/m^3) (ATSDR 2002d).

1.1.10.5 Hexachlorocyclohexane (including lindane)

Hexachlorocyclohexanes (HCH) are a group of manufactured chemicals that do not occur naturally in the environment. HCH has eight chemical forms (called isomers). The four most common are alpha-, beta-, gamma, and delta-HCH. The most common of these is gamma-HCH (also known as lindane). Lindane is a white solid substance that may evaporate into the air as a colorless vapor with a slightly musty odor. It is the common form of hexachlorocyclohexane. Lindane was used as an insecticide on fruit and vegetable crops (including greenhouse vegetables and tobacco) and forest crops (including Christmas trees). It is still used in ointments to treat head and body lice, and scabies. Lindane has not been produced in the United States since 1977. It is still imported to and formulated in the United States (ATSDR 2002de).

In air, HCH can be present as a vapor or attached to small particles such as soil or dust. Lindane can remain in the air for up to 17 weeks and travel long distances. Particles with attached HCH may be removed from the air by rain. In soil, sediments, and water, it is broken down by algae, fungi, and bacteria to less harmful substances. HCH isomers are broken down quickly in water; lindane does not remain in water longer than 30 days. The length of time that HCH isomers remain in soil is not known. It can accumulate in the fatty tissue of fish.

Humans may be exposed to HCH by eating contaminated foods, such as plants, meat, and milk, or by breathing contaminated air in or near factories where products using HCH are made. Humans can also be exposed through skin when applied as a lotion or shampoo to control lice and scabie or by drinking contaminated water or breathing contaminated air near waste sites or landfills. Some people who breathed contaminated workplace air during the manufacturing of pesticides, including lindane, had blood disorders, dizziness, headaches, and changes in the levels of sex hormones. Some people who swallowed large amounts had seizures and sometimes died. The Federal government has made several recommendations to protect human health, including:

- The EPA has set a limit in drinking water of 0.2 parts of lindane per billion parts of water (0.2 ppb). The EPA requires that spills or accidental discharges of lindane into the environment of 1 pound or more must be reported to the EPA (ATSDR 2002de).

- The OSHA, the NIOSH, and the American Conference of Governmental Industrial Hygienists (ACGIH) recommend a maximum level of 0.5 milligrams lindane per cubic meter (0.5 mg/m^3) of workplace air for an 8-hour workday, 40-hour workweek. These agencies advise avoiding eye and skin contact because this may be a route of significant exposure (ATSDR 2002de).

1.1.10.6 Endosulfan

Endosulfan is a pesticide. It is a cream- to brown-colored solid that may appear in the form of crystals or flakes. It has a smell like turpentine, but does not burn. It does not occur naturally in the environment. Endosulfan is used to control insects on food and non-food crops and as a wood preservative (ATSDR 2002c).

Endosulfan enters the air, water, and soil during its manufacture and use. It is often sprayed onto crops and the spray may travel long distances before it lands on crops, soil, or water. Endosulfan on crops usually breaks down in a few weeks, but endosulfan sticks to soil particles and may take years to completely break down. Endosulfan does not dissolve easily in water. Endosulfan in surface water is attached to soil particles floating in water or attached to soil at the bottom. Endosulfan can build up in the bodies of animals that live in endosulfan-contaminated water.

Humans may be exposed to endosulfan by eating food contaminated with endosulfan, but levels in foods are very low. People working in industries involved in making endosulfan or working as pesticide applicators can also be exposed. Skin contact with soil containing endosulfan can also cause exposure.

Endosulfan affects the central nervous system and prevents it from working properly. Hyperactivity, nausea, dizziness, headache, or convulsions have been observed in adults exposed to high doses. Severe poisoning may result in death. The federal government has made several recommendations to protect human health, including:

- The EPA recommends that the amount of endosulfan in rivers, lakes, and streams should not be more than 74 parts per billion (74 ppb) (ATSDR 2002c).
- The FDA allows no more than 24 parts per million (24 ppm) endosulfan on dried tea (ATSDR 2002c).
- EPA allows no more than 0.1 to 2 ppm endosulfan on other raw agricultural products (ATSDR 2002c).

1.1.10.7 Toxaphene

Toxaphene is an insecticide containing over 670 chemicals. It is usually found as a solid or gas, and in its original form it is a yellow to amber waxy solid that smells like turpentine. It does not burn and evaporates when in solid form or when mixed with liquids. Toxaphene is also known as camphechlor, chlorocamphene, polychlorocamphene, and chlorinated camphene. Toxaphene was one of the most heavily used insecticides in the United States until 1982, when it was canceled for most uses; all uses were banned in 1990. It was used primarily in the southern United States to control insect pests on cotton and other crops. It was also used to control insect pests on livestock and to kill unwanted fish in lakes (ATSDR 2002f).

Toxaphene may enter the environment from hazardous waste sites. It may enter the air by evaporation. It does not dissolve well in water, so it is more likely to be found

in air, soil, or sediment at the bottom of lakes or streams, than in surface water. Toxaphene breaks down very slowly in the environment. Toxaphene accumulates in fish and mammals.

People who breathe air near a hazardous waste site where toxaphene was disposed could be exposed to it. Eating contaminated soil could expose infants or toddlers. People who eat large quantities of fish and shellfish, which were contaminated with toxaphene, could be exposed. People who drink water from wells containing toxaphene could also be exposed.

Breathing, eating, or drinking high levels of toxaphene could damage the lungs, nervous system, and kidneys, and can even cause death. However, since toxaphene is no longer used in the United States, most people would not be exposed to high levels of it. People could be exposed to low levels of it; however, there is no information on how low levels affect people. Federal agencies have made several recommendations to protect human health, including:

- The EPA has set a drinking water standard of 0.003 milligrams of toxaphene per liter of drinking water (0.003 mg/L) (ATSDR 2002f).
- The EPA also requires spills or accidental releases into the environment of 1 pound or more of toxaphene be reported.
- The OSHA has set a permissible exposure limit of 0.5 milligrams toxaphene per cubic meter of air (0.5 mg/m3) for an 8-hour workday, 40 hour workweek(ATSDR 2002f).
- NIOSH recommends that toxaphene levels should be as low as possible in the workplace due to its potential carcinogenicity (ATSDR 2002f).
- The American Conference of Governmental Industrial Hydienists (ACGIH) recommend 0.5 mg/m3 for an 8-hour workday, 40-hour workweek. They also recommend that 1 mg/m3 be considered a level that should not be exceeded in a 15-minute period.

1.1.11 Mercury

Mercury is a naturally occurring metal that has several forms. The metallic mercury is a shiny, silver-white, odorless liquid. If heated, it is a colorless, odorless gas. Mercury combines with other elements, such as chlorine, sulfur, or oxygen, to form inorganic mercury compounds or "salts," which are usually white powders or crystals. Mercury also combines with carbon to make organic mercury compounds. The most common one, methylmercury, is produced mainly by microscopic organisms in the water and soil. More mercury in the environment can increase the amounts of methylmercury that these small organisms make. Metallic mercury is used to produce chlorine gas and caustic soda, and is also used in thermometers,

dental fillings, and batteries. Mercury salts are sometimes used in skin lightening creams and as antiseptic creams and ointments (ATSDR 1999b).

Inorganic mercury (metallic mercury and inorganic mercury compounds) enters the air from mining ore deposits, burning coal and waste, and from manufacturing plants. It enters the water or soil from natural deposits, disposal of wastes, and volcanic activity. Methylmercury may be formed in water and soil by bacteria. Methylmercury builds up in the tissues of fish. Larger and older fish tend to have the highest levels of mercury. Exposure to mercury can occur through eating fish or shellfish contaminated with methylmercury; breathing vapors in air from spills, incinerators, and industries that burn mercury-containing fuels, release of mercury from dental work and medical treatments; and breathing contaminated workplace air or skin contact during use in the workplace (from businesses and industries that use mercury).

The nervous system is very sensitive to all forms of mercury. Methylmercury and metallic mercury vapors are more harmful than other forms, because more mercury in these forms reaches the brain. Exposure to high levels of metallic, inorganic, or organic mercury can permanently damage the brain, kidneys, and developing fetus. Effects on brain functioning may result in irritability, shyness, tremors, changes in vision or hearing, and memory problems. Short-term exposure to high levels of metallic mercury vapors may cause effects including lung damage, nausea, vomiting, diarrhea, increases in blood pressure or heart rate, skin rashes, and eye irritation. Federal agencies have made several recommendations to protect human health, including:

- The EPA has set a limit of 2 parts of mercury per billion parts of drinking water (2 ppb) (ATSDR 1999b).
- The FDA has set a maximum permissible level of 1 part of methylmercury in a million parts of seafood (1 ppm) (ATSDR 1999b).
- The OSHA has set limits of 0.1 milligram of organic mercury per cubic meter of workplace air (0.1 mg/m3) and 0.05 mg/m3 of metallic mercury vapor for 8-hour shifts and 40-hour workweeks (ATSDR 1999b).

1.1.12 PCBs

Polychlorinated biphenyls (PCBs) are mixtures of up to 209 individual chlorinated compounds (known as congeners). There are no known natural sources of PCBs. PCBs are either oily liquids or solids that are colorless to light yellow. Some PCBs can exist as a vapor in air. PCBs have no known smell or taste. Many commercial PCB mixtures are known in the U.S. by the trade name Aroclor (ATSDR 2000).

PCBs have been used as coolants and lubricants in transformers, capacitors, and other electrical equipment because they don't burn easily and are good insulators. The manufacture of PCBs was stopped in the U.S. in 1977 because of evidence they build

up in the environment and can cause harmful health effects. Products made before 1977 that may contain PCBs include old fluorescent lighting fixtures and electrical devices containing PCB capacitors, and old microscope and hydraulic oils.

PCBs entered the air, water, and soil during their manufacture, use, and disposal; from accidental spills and leaks during their transport; and from leaks or fires in products containing PCBs. PCBs can still be released to the environment from hazardous waste sites; illegal or improper disposal of industrial wastes and consumer products; leaks from old electrical transformers containing PCBs; and burning of some wastes in incinerators. PCBs do not readily break down in the environment and thus may remain there for very long periods of time. PCBs can travel long distances in the air and be deposited in areas far away from where they were released. In water, a small amount of PCBs may remain dissolved, but most stick to organic particles and bottom sediments. PCBs also bind strongly to soil. PCBs are taken up by small organisms and fish in water. They are also taken up by other animals that eat these aquatic animals as food. PCBs accumulate in fish and marine mammals, reaching levels that may be many thousands of times higher than in water.

The most commonly observed health effects in people exposed to large amounts of PCBs are skin conditions such as acne and rashes. Studies in exposed workers have shown changes in blood and urine that may indicate liver damage. PCB exposures in the general population are not likely to result in skin and liver effects. Animals that ate food containing large amounts of PCBs for short periods of time had mild liver damage and some died. Animals that ate smaller amounts of PCBs in food over several weeks or months developed various kinds of health effects, including anemia; acne-like skin conditions; and liver, stomach, and thyroid gland injuries. Other effects of PCBs in animals include changes in the immune system, behavioral alterations, and impaired reproduction. Federal agencies have made several recommendations to protect human health, including

- The EPA has set a limit of 0.0005 milligrams of PCBs per liter of drinking water (0.0005 mg/L) (ATSDR 2002).
- Discharges, spills or accidental releases of 1 pound or more of PCBs into the environment must be reported to the EPA (ATSDR 2002).
- The FDA requires that infant foods, eggs, milk and other dairy products, fish and shellfish, poultry and red meat contain no more than 0.2-3 parts of PCBs per million parts (0.2-3 ppm) of food (ATSDR 2002).
- Many states also have established fish and wildlife consumption advisories for PCBs (ATSDR 2002).

1.1.13 Selenium

Selenium is a metal commonly found in rocks and soil. In the environment, selenium is not often found in the pure form. Much of the selenium in rocks is combined with

sulfide minerals or with silver, copper, lead, and nickel minerals. Selenium and oxygen combine to form several compounds. Selenium sulfide is a bright red-yellow powder used in anti-dandruff shampoo. Industrially produced hydrogen selenide is a colorless gas with a disagreeable odor. It is probably the only selenium compound that might pose a health concern in the workplace. Selenium dioxide is an industrially produced compound that dissolves in water to form selenious acid (ATSDR 1996a).

Small selenium particles in the air settle to the ground or are taken out of the air in rain. Soluble selenium compounds in agricultural fields can leave the field in irrigation drainage water. Selenium can collect in animals that live in water containing high levels of it. Exposure to selenium occurs by breathing air that contains it and by eating food, drinking water, or taking dietary supplements that contain it.

People exposed to very high levels of selenium have reported dizziness, fatigue, irritation, collection of fluid in the lungs, and severe bronchitis. The exact levels at which these effects occur are not known. Upon contact with skin, selenium compounds have caused rashes, swelling, and pain. Selenium compounds can be harmful at daily dietary levels 5–10 times higher than the daily requirement. Accidentally swallowing a large amount of selenium (for example, a very large quantity of selenium supplement pills) could be life-threatening without immediate medical treatment. If too much selenium is eaten over long periods of time, brittle hair and deformed nails can develop. People may also lose feeling and control in the arms and legs. Federal agencies have made several recommendations to protect human health, including:

- The EPA maximum contaminant level (MCL) for selenium in drinking water is 50 parts of selenium per billion parts of water (50 ppb) (ATSDR 1996a).

- The OSHA exposure limit for selenium compounds in workplace air is 0.2 milligrams of selenium per cubic meter of air (0.2 mg/m^3) for an 8-hour day over a 40-hour workweek (ATSDR 1996a).

1.1.14 Unknown Toxicity

An unknown toxicity is defined as a toxicity that has been found within a waterbody, but further testing has not been done to discover what the toxicity specifically is (N. Richard, pers. Comm., 2002). Unknown toxicities are found within waterbodies that have been monitored, tested, and sampled for toxicity in general and during testing, organism within the tested water have died.

1.1.15 Zinc

Zinc is one of the most common elements in the earth's crust. It is found in air, soil, and water, and is present in all foods. Pure zinc is a bluish-white shiny metal. Zinc has many commercial uses: as coatings to prevent rust, in dry cell batteries, and

mixed with other metals to make alloys like brass and bronze. Zinc combines with other elements to form zinc compounds. Common zinc compounds found at hazardous waste sites include zinc chloride, zinc oxide, zinc sulfate, and zinc sulfide. Zinc compounds are widely used in industry to make paint, rubber, dye, wood preservatives, and ointments (ATSDR 1994).

Zinc is released into the environment by natural processes, but most comes from activities of people like mining, steel production, coal burning, and burning of waste. It attaches to soil, sediments, and dust particles in the air. Zinc compounds can move into the groundwater and into lakes, streams, and rivers. Most of the zinc in soil stays bound to soil particles. It builds up in fish and other organisms, but not in plants. Exposure to zinc can occur through ingesting small amounts present in food and water; drinking contaminated water near manufacturing or waste sites; and breathing zinc particles in the air at manufacturing sites.

Zinc is an essential element in the diet. Too little zinc can cause health problems, but too much zinc is also harmful. Eating large amounts of zinc, even for a short time, can cause stomach cramps, nausea, and vomiting. Taken longer, it can cause anemia, pancreas damage, and lower levels of high-density lipoprotein cholesterol (the good form of cholesterol). Breathing large amounts of zinc (as dust or fumes) can cause a specific short-term disease called metal fume fever. Long-term effects are unknown. Federal agencies have made several recommendations to protect human health, including:

- EPA recommends that there be no more than 5 parts of zinc in 1 million parts of drinking water (5 ppm) because of taste. EPA also requires that releases of more than 1,000 (or in some cases 5,000) pounds of zinc or its compounds into the environment be reported (ATSDR 1994).

- OSHA has set a maximum concentration limit for zinc chloride fumes in workplace air of 1 milligram of zinc per cubic meter of air (1 mg/m^3) for an 8-hour workday over a 40-hour workweek and 5 mg/m^3 for zinc oxide fumes (ATSDR 1994).

- NIOSH has set the same standards for up to a 10-hour workday over a 40-hour workweek.

1.2.1 Beneficial Uses

State law defines beneficial uses of California's waters that may be protected against quality degradation to include (but not limited to) "...domestic; municipal; agricultural and industrial supply; power generation; recreation; aesthetic enjoyment; navigation; and preservation and enhancement of fish, wildlife, and other aquatic resources or preserves" (Water Code Section 13050(f)).

Beneficial use designation (and water quality objectives) must be reviewed at least once during each three-year period for the purpose of modification as appropriate (40

CFR 131.20). The beneficial uses, and abbreviations, listed below are standard basin plan designations (RWQCBCV 1998).

Municipal and Domestic Supply (MUN) - Uses of water for community, military, or individual water supply systems including, but not limited to, drinking water supply.

Agricultural Supply (AGR) - Uses of water for farming, horticulture, or ranching including, but not limited to, irrigation (including leaching of salts), stock watering, or support of vegetation for range grazing.

Areas of Special Biological Significance (ASBS) - Areas designated by the SWRCB. These include marine life refuges, and designated areas where the preservation and enhancement of natural resources requires special attention.

Industrial Service Supply (IND) - Uses of water for industrial activities that do not depend primarily on water quality including, but not limited to, mining, cooling water supply, hydraulic conveyance, gravel washing, fire protection, or oil well repressurization.

Industrial Process Supply (PRO) - Uses of water for industrial activities that depend primarily on water quality.

Ground Water Recharge (GWR) - Uses of water for natural or artificial recharge of ground water for purposes of future extraction, maintenance of water quality, or halting of saltwater intrusion into freshwater aquifers.

Freshwater Replenishment (FRSH) - Uses of water for natural or artificial maintenance of surface water quantity or quality.

Navigation (NAV) - Uses of water for shipping, travel, or other transportation by private, military, or commercial vessels.

Hydropower Generation (POW) - Uses of water for hydropower generation.

Water Contact Recreation (REC-1) - Uses of water for recreational activities involving body contact with water, where ingestion of water is reasonably possible. These uses include, but are not limited to, swimming, wading, water-skiing, skin and scuba diving, surfing, canoeing, white water activities, fishing, or use of natural hot springs.

Non-contact Water Recreation (REC-2) - Uses of water for recreational activities involving proximity to water, but where there is generally no body contact with water, nor any likelihood of ingestion of water. These uses include, but are not limited to, picnicking, sunbathing, hiking, beachcombing, camping, boating, tidepool and marine life study, hunting, sightseeing, or aesthetic enjoyment in conjunction with the above activities.

Commercial and Sport Fishing (COMM) - Uses of water for commercial or recreational collection of fish, shellfish, or other organisms including, but not limited to, uses involving organisms intended for human consumption or bait purposes.

Aquaculture (AQUA) - Uses of water for aquaculture or mariculture operations including, but not limited to, propagation, cultivation, maintenance, or harvesting of aquatic plants and animals for human consumption or bait purposes.

Warm Freshwater Habitat (WARM) - Uses of water that support warm water ecosystems including, but not limited to, preservation or enhancement of aquatic habitats, vegetation, fish, or wildlife, including invertebrates.

Cold Freshwater Habitat (COLD) - Uses of water that support cold water ecosystems including, but not limited to, preservation or enhancement of aquatic habitats, vegetation, fish, or wildlife, including invertebrates.

Estuarine Habitat (EST) - Uses of water that support estuarine ecosystems including, but not limited to, preservation or enhancement of estuarine habitats, vegetation, fish, shellfish, or wildlife (e.g., estuarine mammals, waterfowl, shorebirds).

Wetland Habitat (WET) - Uses of water that support wetland ecosystems, including, but not limited to, preservation or enhancement of wetland habitats, vegetation, fish shellfish, or wildlife, and other unique wetland functions which enhance water quality, such as providing flood and erosion control, stream bank stabilization, and filtration and purification of naturally occurring contaminants.

Wildlife Habitat (WILD) - Uses of water that support terrestrial or wetland ecosystems including, but not limited to, preservation and enhancement of terrestrial habitats or wetlands, vegetation, wildlife (e.g., mammals, birds, reptiles, amphibians, invertebrates), or wildlife water and food sources.

Preservation of Biological Habitats of Special Significance (BIOL) - Uses of water that support designated areas or habitats, such as established refuges, parks, sanctuaries, ecological reserves, or Areas of Special Biological Significance, where the preservation or enhancement of natural resources requires special protection.

Rare, Threatened, or Endangered Species (RARE) - Uses of water that support aquatic habitats necessary, at least in part, for the survival and successful maintenance of plant or animal species established under State or Federal law as rare, threatened or endangered.

Migration of Aquatic Organisms (MIGR) - Uses of water that support habitats necessary for migration or other temporary activities by aquatic organisms, such as anadromous fish.

Spawning, Reproduction, and/or Early Development (SPWN) - Uses of water that support high quality aquatic habitats suitable for reproduction and early development of fish.

Shellfish Harvesting (SHELL) - Uses of water that support habitats suitable for the collection of filter feeding shellfish (e.g., clams, oysters, and mussels) for human consumption, commercial, or sports purposes.

Marine Habitat (MAR) - Uses of water that support marine ecosystems, including, but not limited to, preservation or enhancement of marine habitats, vegetation such as kelp, fish, shellfish, or wildlife (e.g., marine mammals, shore birds).

1.3 San Joaquin-Sacramento Delta Region Water Quality

1.3.1 Constituents of Concern

The Delta is currently listed as impaired under Section 303(d) of the CWA for the following constituents: unknown toxicity, mercury, pesticides, and organic enrichment/low dissolved oxygen. The following paragraphs describe Delta water quality conditions with regards to these constituents.

The major sources of metals include abandoned mines, agricultural drainage, and urban runoff. In May and September from 1975 through 1993, DWR measured concentrations of nine trace metals at 11 sampling stations in the Bay-Delta and in Suisun Bay from 1975-1993. Trace metals (most frequently copper) exceeded the guidelines for fresh-water acute and chronic toxicity on 34 occasions (CALFED 2000a). Marine acute and chronic toxicity guidelines were exceeded 181 times, with copper accounting for 160 of these exceedances (CALFED 2000a). The Delta is currently listed as impaired for unknown toxicity under Section 303(d) of the CWA and the unknown toxicity TMDL to protect beneficial uses is scheduled for development by 2011 (see Table 5-5). In addition to trace metals, mining-related activities are known to be a source of mercury in the Delta. The Coast Ranges, on the west side of the Sacramento Valley, contain a large deposit of cinnabar (mercury ore). The majorities of the mercury mines in the Coast Ranges are abandoned and remain unclaimed. During the late 1800s and early 1900s, mercury was intensively mined and refined in the Coast Ranges, and then transported across the Central Valley to the Sierra Nevada for use in placer gold mining operations. Studies conducted by UC Davis and USGS illustrate that the sediments mobilized by hydraulic mining were ultimately transported to the Bay-Delta, where they formed marshes and islands or were deposited in shallow water (CALFED 2000a). The Delta is currently listed as impaired for mercury under Section 303(d) of the CWA. The mercury TMDL to protect beneficial uses is scheduled for development by 2004 (see Table 5-5).

Organophosphate pesticides, such as diazinon and chlorpyrifos, are used in the Central Valley on orchard crops including almonds, peaches, and prunes. These pesticides are applied during the dormant spray season from December through

February. Diazinon and chlorpyrifos also are used by commercial applicators and home owners to control common pests. Diazinon and chlorpyrifos have been detected in surface water during winter and early spring from applications to orchards, in irrigation return water during summer, and in urban runoff samples during both winter and summer. Organochlorine pesticides such as DDT, toxaphene, dieldrin, and chlordane were widely used in the Central Valley until the 1970s and remain very persistent. Residues of these agents are still widespread in the Central Valley and are mobilized during winter storms, by irrigation and dredging, and by construction activities (CALFED 2000a). These more persistent chlorinated hydrocarbon pesticides are consistently found throughout the system at higher levels than the less persistent organophosphate compounds (SWRCB 1997). The Delta is currently listed as impaired for a variety of pesticides including chlorpyrifos, DDT, diazinon, and Group A pesticides under Section 303(d) of the CWA and TMDLs to protect beneficial uses are scheduled for development from 2004 to 2011, depending upon the constituent (see Table 5-5).

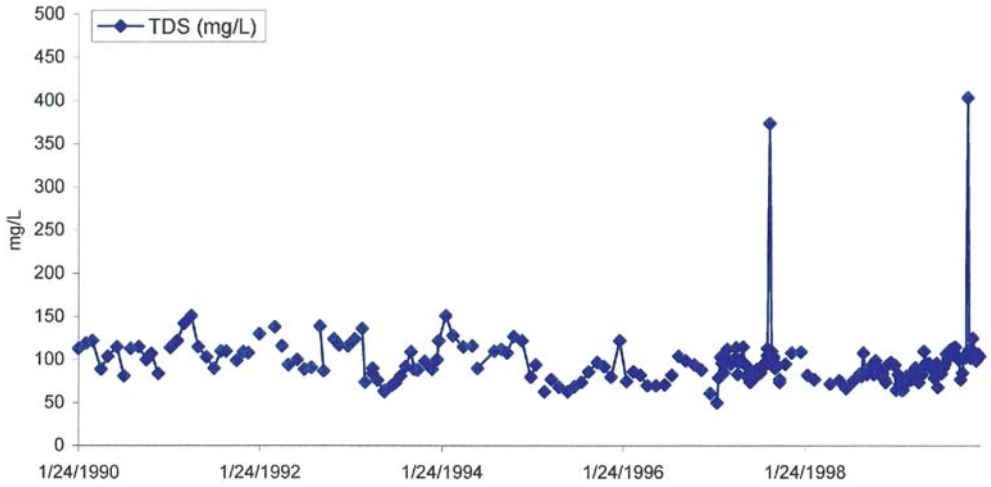
The most serious nutrient enrichment problems in the Delta are found along the lower San Joaquin River and in certain localized areas receiving waste discharges, but having little or no net freshwater flow. These conditions result in low dissolved oxygen levels, which occur mainly in the late-summer and coincide with low river flows and high water temperatures. Channel deepening for navigational purposes further aggravates dissolved oxygen problems. Warm, shallow, dead-end sloughs of the eastern Delta support objectionable populations of planktonic blue-green algae during summer months. Floating and semi-attached aquatic plants, such as water primrose and water hyacinths, frequently clog waterways in the lower San Joaquin River system during the summer. Extensive growths of these plants also have been observed in the waterways of the Delta. These plants interfere with the passage of small boat traffic and contribute to the total organic load in the Bay-Delta system as they break loose and move downstream in the fall and winter. Much of the water in the Delta system is turbid as a result of an abundance of suspended silts, clays, and organic matter. Most of these sediments enter the tidal system with the flow of the major tributary rivers. Some enriched areas are turbid as a result of planktonic algal populations, but inorganic turbidity tends to suppress nuisance algal populations in much of the Delta (SWRCB 1997). The Delta is currently listed as impaired for organic enrichment/low dissolved oxygen under Section 303(d) of the Clean Water Act and TMDLs to protect beneficial uses are scheduled for development by 2004 (see Table 5-5).

1.3.2 Delta Drinking Water Quality Concerns

1.3.2.1 Salinity

Excess salinity in Delta waters may affect agricultural, industrial, and municipal water supply beneficial uses, as well as habitat quality for aquatic biota in the Delta. Sources of salinity include sea-water intrusion, agricultural drainage, municipal wastewater, urban runoff, connate groundwater, and evapotranspiration of plants. Sea-water intrusion is the major source of salinity in the Delta (CALFED 2000a). With

the exception of monitoring stations that are under the direct influence of tidal action, data analyses quantifying the contribution of seawater intrusion to TDS concentrations are scarce (DWR 2001b). However, because the EC of seawater is approximately 50,000 µS/cm, which is approximately 70 to 80 times greater than the daily average EC ranges at Banks Pumping Plant that signals DWR to consider allowing more freshwater into the system, it takes relatively little seawater to increase TDS or EC levels (DWR 2001b). Agricultural drainage, particularly from the San Joaquin Valley, is another important source of salinity, especially in the south Delta (CALFED 2000a).



Salinity control is necessary because the Delta is influenced by the ocean, and Delta water channels are at or below sea level (SWRCB 1997). The Sacramento and San Joaquin rivers unite at the western end of the Sacramento-San Joaquin Delta at Suisun Bay. From Suisun Bay, water flows through the Carquinez Strait into San Pablo Bay, then south into San Francisco Bay and out to sea through the Golden Gate Bridge (SWRCB 1997). Unless repelled by continuous seaward flow of freshwater, sea water will advance up the Estuary and into the Delta and degrade water quality (SWRCB 1997). Salinity varies geographically within the Delta varies seasonally within the Delta, and varies depending upon water year type.

CVP/SWP exports and pumping patterns have the potential to influence the direction of flow at various locations throughout the Delta, and thereby potentially affect the salinity at export locations. Operation of the Banks Pumping Plant and Tracy Pumping Plant draws high quality Sacramento River water across the Delta and restricts the low quality area to the southeast corner (SWRCB 1997). Each portion of the Delta is dominated by different hydraulic variables and therefore salinity varies within different sections of the Delta.

The Sacramento and San Joaquin rivers contribute approximately 61 percent and 33 percent, respectively, to tributary inflow TDS concentrations within the Delta. The relative concentrations of TDS are low in the Sacramento River, but because of its large volumetric contribution, the river contributes the majority of the TDS load supplied by tributary inflow to the Delta (DWR 2001b). TDS monitoring in the Sacramento River at Greenes Landing/Hood, downstream of the City of Sacramento and downstream of the last urban discharge point, illustrates that TDS concentrations at this location are consistently below the secondary MCL of 500 mg/L (see Figure G-1). Although actual flow from the San Joaquin River is lower than the Sacramento River, the TDS concentrations in San Joaquin River water averages approximately seven times that of the Sacramento River, resulting in a net contribution of 33 percent of the TDS from tributary inflow to the Delta.

In addition to varying geographically within the Delta, salinity varies seasonally, depending on the quantity and quality of freshwater inflows. During winter and early-spring, flows through the Delta are usually above the minimum required to control salinity. At least for a few months in the summer and fall of most years, however, salinity must be carefully monitored and controlled (SWRCB 1997). During

the summer, salinity in the Delta may increase due to decreased inflows or increased salt loading resulting from agricultural runoff. Additionally, decreased inflow during the late summer increases the possibility that reverse flow would cause increased intrusion of saline water within the Delta. Salinity control and monitoring is provided by the CVP and SWP, and regulated by the SWRCB under its water rights authority. Salinity must be carefully monitored because water exported from the Delta for delivery to CVP and SWP contractors is used for a variety of municipal, industrial, and agricultural uses (SWRCB 1997, CALFED 2002a).

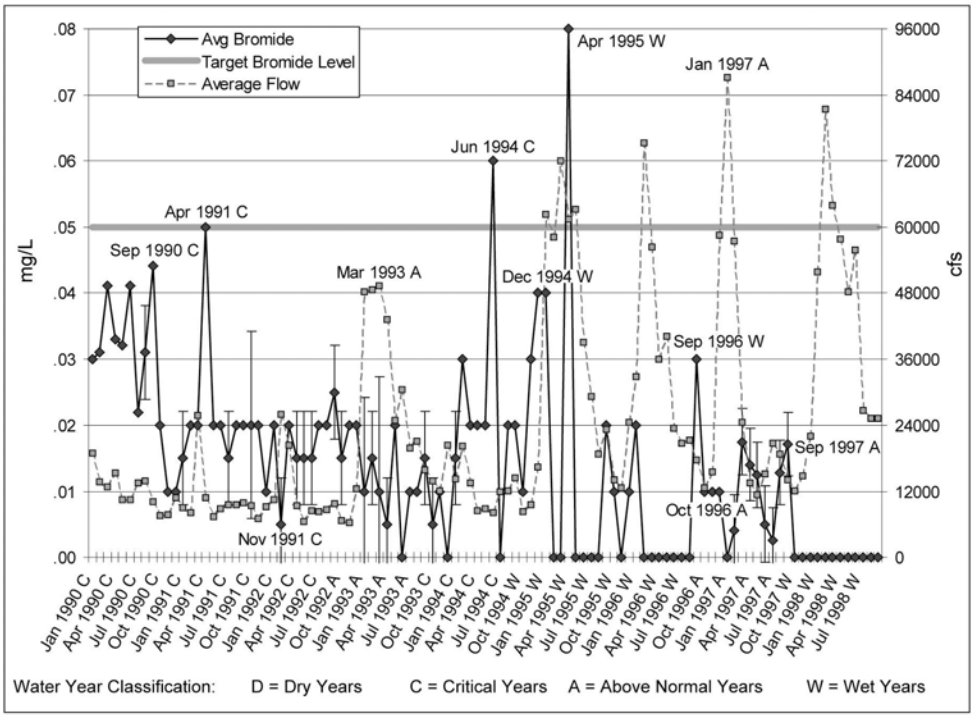
Figure G-1
TDS (mg/L) Sacramento River at Greenes Landing/Hood, 1990 to 1999



1.3.2.2 Bromide

Bromides are formed by the reaction of bromine or a bromide with another substance and are widely distributed in nature. The presence of bromide in source waters may shift the proportion of bromine containing DBPs (such as THMs) to higher levels (CALFED 2000b). The existing MRDL limits the sum of the four species, termed TTHMs, at 0.080 mg/L (see Table 5-1). Health effects potentially resulting from long-term ingestion of drinking water containing THMs in excess of EPA's standard may include problems with the liver, kidneys, or central nervous system, and long-term exposure may result in an increased risk of getting cancer (EPA 2003). Because disinfection with chlorine can result in formation of THMs, some wastewater treatment facilities are switching to ozone as a disinfectant. Use of ozone as a disinfectant has the advantage that it does not produce THMs (Sawyer et al. 1994). However, bromate is formed when ozone contacts water with bromide in it. Bromate also is regulated in drinking water because long-term exposure to bromate may result in an increased cancer risk (EPA 2003).

The primary source of bromide in Delta waters is sea-water intrusion (CALFED 2000a). DWR's Municipal Water Quality Investigations (MWQI) program investigated seawater intrusion at different geographic areas in the Delta: in the northern Delta on the Sacramento River at Greenes Landing/Hood, in the southern Delta in the San Joaquin River near Vernalis/Mossdale, and in the western Delta at Station 9 just upstream of Clifton Court Forebay (DWR 2001b). In addition, bromide levels were monitored at Banks Pumping Plant. Bromide data were collected from 1990 to 1998 at these four locations. In the northern Delta on the Sacramento River at Greenes Landing/Hood, 98 percent of the samples collected were below the CALFED target level of 0.05 mg/L. Although the Sacramento River contributes approximately 20 percent of the total bromide loading to the Delta, in terms of concentration, bromide levels in the Sacramento River are not a concern for drinking water purposes (DWR 2001b). The seasonal changes in bromide concentrations at three locations are illustrated in Figure G-2. As shown in Figure G-2, during eight years of quarterly monitoring, the proposed CALFED target level of 0.05 mg/L bromide was exceeded only three times at Greens Landing/Hood on the Sacramento River (DWR 2001b).

In contrast to the Sacramento River, 88 percent of the samples collected in the southern Delta (San Joaquin River near Vernalis/Mossdale) and 87 percent of the samples collected in the western Delta (Station 9) exceeded CALFED's recommended target level (DWR 2001b). Because seawater contains approximately 66.8 mg/L bromide, more than 1,300 times the 0.05 mg/L export target, it takes relatively little seawater to increase bromide levels (DWR 2001b). Approximately 90 percent of the samples at the Banks Pumping Plant exceeded the proposed target (DWR 2001b).

Overall, bromide patterns in the Delta are similar to salinity patterns in the Delta (DWR 2001b). Like salinity, bromide concentrations are highest in the west and south Delta channels affected by the San Joaquin River (DWR 2001b). Like salinity, bromide concentrations are higher in dry years than in wet years and bromide concentrations are higher during low Delta outflows as compared to medium or high flows (DWR 2001b). This pattern is not unexpected as chloride and bromide are generally co-located and would be expected to exhibit similar behavior (R. Breuer, DWR, pers. comm.).

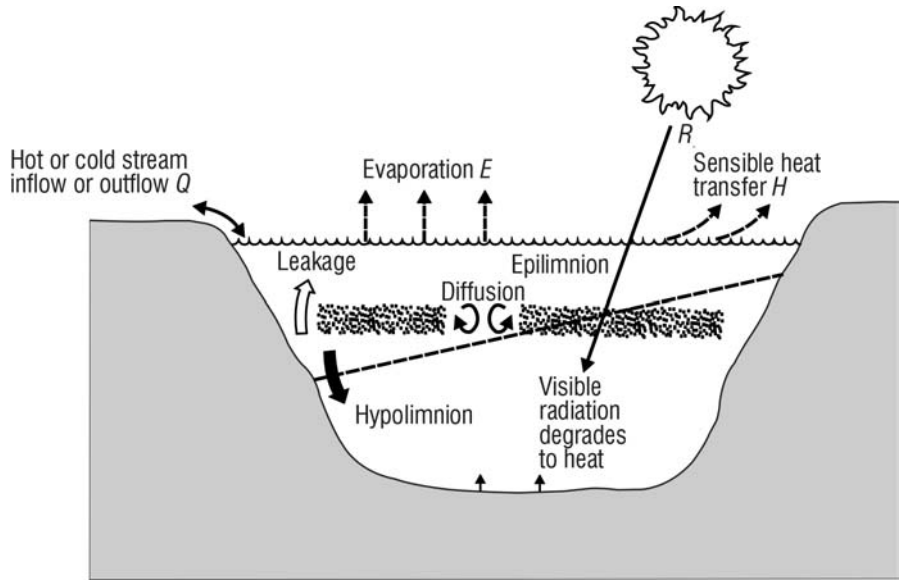
Sacramento River at Greenes Landing/Hood – Monthly Average Bromide Concentrations (±1 Standard Deviation) with Sacramento River Flow

1.4 Reservoir Water Quality

This section describes how lakes and reservoirs function, and the limnological processes that occur within them to provide a better understanding of water quality.

Physiochemical Reservoir Processes



Certain physiochemical parameters (water temperature and dissolved oxygen) associated with lakes and reservoirs typically exhibit direct relationships to depth. Because water density changes with water temperature, most waterbodies have a temperature gradient that decreases with depth. In reservoirs, warmer water generally is found near the surface and the volume of warm water tends to gradually decrease down through the water column. Conversely, a greater volume of cold water is found near the bottom of the reservoir, and this is often known as the coldwater pool (Horne, A.J. and Goldman C.R. 1994; Wetzel, R.G. 1983; Moss, B. 1998).

Because the solubility of dissolved oxygen in water is related to changes in pressure and temperature, cold water generally contains a greater percentage of dissolved oxygen as compared to warm water. However, in most systems there are additional demands that may affect this relationship. Plant and animal respiration can consume large amounts of dissolved oxygen but the major consumption of oxygen in lakes and reservoirs is attributed to bacterial respiration associated with the decomposition of organic matter settling out of the water column. Additionally, wind action across the

surface of lakes promotes mixing, which generally results in greater dissolved oxygen concentrations near the surface (Horne and Goldman 1994, Wetzel 1983; Moss 1998).

Summer/Winter - Stratification/Mixing

In the spring and early summer, water near the lake surface begins to warm as it absorbs energy from increased solar radiation associated with longer daylight hours (Figure G-3). Because of the thermal properties associated with water, the warmer layers of water remain near the surface while denser, colder water sinks deeper into the water column. Over time, this creates distinct thermal layers (known as the epilimnion, metalimnion/thermocline and hypolimnion) within the water column. Once the spring thermocline is established, it is thermodynamically stable and usually can be destroyed only by cooling of the epilimnion. At this point, the hypolimnion is effectively isolated from the surface and dissolved oxygen cannot be replenished except by diffusion from the metalimnion, which is very slow (Horne and Goldman 1994; Wetzel 1983; Moss 1998).

Source: Horne, A.J. and Goldman C.R. 1994

Figure G-3
Horizontal Cross-Sectional View Of The Physiochemical Processes And Stratification Layers Occurring In Lakes And Reservoirs

In the fall, less solar radiation reaches the lake surface during the day, while heat losses at the surface of the water are greater at night than they are deeper in the water column. Cooling water at the surface is denser than warmer water below and so it sinks, causing the warmer water to rise up to the surface. These convective currents and wind-induced mixing begin to weaken the thermocline. The epilimnion increases in depth as water temperature decreases. Eventually the water temperature and density differences between adjacent water layers are so slight that a strong wind can

overcome the remaining resistance to mixing in the water column and the lake undergoes fall overturn, mixing from top to bottom. Fall overturn causes oxygen-saturated water at the surface to be distributed throughout the various depths of the epilimnetic and hypolimnetic layers. When circulation is complete, dissolved oxygen continues at saturation in accordance with solubility at existing temperatures. These mixing events are important because they enable low or depleted oxygen stores in the hypolimnion and near the lakebed to be replenished. This also ensures that aerobic activities associated with bacterial decomposition in and above the lake sediments continue to occur. Additionally, mixing distributes organic nutrients (e.g., nitrogen and phosphorous) which are accumulated at the bottom of the lake throughout the summer, through the water column (Horne and Goldman 1994; Wetzel 1983; Moss 1998).

Potential Lake Pollutants: Nutrients/Metals/Sedimentation

Healthy lake ecosystems contain small quantities of nutrients from natural sources. An increased or accelerated input of nutrients (primarily nitrogen and phosphorous) may disrupt the balance of lake ecosystems by altering physical, chemical and biological processes within the system. Excessive nutrients can stimulate increased productivity, which can lead to short-term population explosions of algae and aquatic macrophytes. Eventually the algae and other vegetation die off and sink to the bottom of the lake where it undergoes bacterial decomposition. As the bacteria continue to break down the organic matter, the decomposition process elicits a high biochemical oxygen demand, which can deplete dissolved oxygen in the water. At a substantial level, this may deprive fish and other aquatic organisms of oxygen, which in turn can lead to fish kills or produce foul odors in the water (Horne and Goldman 1994; Wetzel 1983; Moss 1998).

After nutrient loading, metals are typically the second most common lake pollutant of concern and are often found to accumulate in lake sediments. These substances are a concern because many of them are harmful to humans and aquatic organisms. While many metals become concentrated in the sediment, they generally remain there unless disturbed and re-suspended in the water column. Reservoir drawdown has the potential to alter the concentration and mobility of metals found in the sediment within and around the reservoir by reducing the volume of the storage pool. Additionally, exposing a greater amount of the shoreline acreage surrounding the waterbody could potentially lead to increased shoreline erosion, which may increase the amount of sediment loading and suspended solids within the reservoir. In addition to concerns associated with metals, increased sedimentation may reduce water clarity or impair physiological mechanisms associated with aquatic organisms (Horne and Goldman 1994; Wetzel 1983; Moss 1998).

Reservoir and river management objectives may have conflicting resource goals, which require management coordination to ensure that the needs of both resources are being adequately met. In some situations, trade-offs may need to occur between the upstream reservoir and river reaches downstream. Management actions may call for increased reservoir releases to provide for downstream requirements. Providing

downstream benefits (e.g., flow and habitat improvements for fish and wildlife, power generation, agricultural and municipal water diversions) from increases in reservoir flow releases may lead to reductions to reservoir storage and could negatively affect reservoir-related water quality parameters by resulting in: 1) lower surface water elevations within the reservoir; 2) reductions in the volume of the cold water pool; and 3) alteration of pollutant concentrations. Such changes to reservoir water quality could also result in direct and indirect affects to reservoir-dependent aquatic and human uses such as fisheries and primary and secondary contact recreational use.

1.5 Environmental Consequences/Environmental Impacts of the Flexible Purchase Alternative in the Upstream from the Delta Region – Detailed Discussion

The following is a detailed analysis of the effects of the Flexible Purchase Alternative in the Upstream from the Delta Region. These effects are summarized in Chapter 5 of the EWA Draft EIS/EIR. Chapter 5 also includes a complete discussion of effects to the Delta Region and Export Service Area of EWA actions.

The analysis provides a program-specific evaluation of the Flexible Purchase Alternative as compared to the Baseline Condition. The anticipated change that would occur under each scenario is compared to the significance criteria to ascertain whether the EWA Program alternative would result in "*beneficial*," "*less-than-significant*," or "*significant*" impacts on water quality.

1.5.1 Stored Reservoir Water (Including Stored Water Acquired from Crop Idling and Groundwater Substitution)

1.5.1.1 CVP/SWP Reservoirs Within the Upstream from the Delta Region

Lake Shasta

EWA acquisition of Sacramento River contractor water via stored reservoir water, groundwater substitution and crop idling under the Flexible Purchase Alternative would alter surface water elevation and reservoir storage in Lake Shasta, relative to the Baseline Condition.

Under the Flexible Purchase Alternative, long-term average end-of-month water surface elevation in Lake Shasta would remain essentially equivalent to the Baseline Condition during every month of the year. The long-term average end-of-month water surface elevation in Lake Shasta would not decrease by more than 1 foot in any of the months included in the analysis. Long-term average end-of-month water surface elevation would decrease by 1 foot in August (Table G-1). Under the Flexible Purchase Alternative, the end-of-month water surface elevation in Lake Shasta would be essentially equivalent to or greater than the Baseline Condition for 831 months of the 864 months included in the analysis. In Lake Shasta, hydrologic conditions under the Flexible Purchase Alternative would result in reductions in the end-of-month water surface elevation from the months of July and August. Reductions in the end-

of-month water surface elevation would range from 5 feet in July to 4 feet in August [Appendix H, p. 181 to 192].

Table G-1
Long-term Average Lake Shasta End-of-Month Elevation Under the Baseline Condition and Flexible Purchase Alternative

Month	Average Elevation[1] (feet msl)		
	Baseline Condition	Flexible Purchase Alternative	Difference
Jan	998	998	0
Feb	1011	1011	0
Mar	1027	1027	0
Apr	1037	1037	0
May	1036	1036	0
Jun	1024	1024	0
Jul	1001	1001	0
Aug	984	983	-1
Sep	977	977	0
Oct	973	972	0
Nov	977	977	0
Dec	985	985	0

[1] Based on 72 years modeled.
Note: For a further description of the methodology used for the data assessment, please refer to Section 5.2.1 Assessment Methods.

Under the Flexible Purchase Alternative, the end-of-month water surface elevation in Lake Shasta during critical years would be essentially equivalent to or greater than the Baseline Condition for 106 months of the 132 months included in the analysis. Within critical years, the long-term average end-of-month water surface elevation in Lake Shasta would not decrease or increase in any month of the year except during July through September. Within critical years, the long-term average end-of-month water surface elevation in Lake Shasta would increase in 2 of the 11 years included in the analysis in July and in 1 of the 11 years included in the analysis in September. The long-term average end-of-month water surface elevation increase during critical years would range from 0.4 feet in July to less than 0.1 feet in September, representing a 0.05 percent and 0.01 percent increase, respectively, as compared to the Baseline Condition. Decreases within critical years would occur in 9 of the 11 years included in the analysis in July, in 11 of the 11 years included in the analysis in August, and in 6 of the 11 years in the analysis in September. The long-term average end-of-month water surface elevation decrease during critical years would range from 2.3 feet in July to 0.1 feet in September, representing a 0.26 percent to 0.01 percent decrease during that period, as compared to the Baseline Condition [Appendix H, p. 1001].

Under the Flexible Purchase Alternative, the end-of-month water surface elevation in Lake Shasta during dry years would be essentially equivalent to or greater than the Baseline Condition for 170 months of the 192 months included in the analysis. Within dry years, the long-term average end-of-month water surface elevation in Lake Shasta would not decrease or increase in any month of the year except during July through September. The increases would occur in 1 of the 16 years included in the analysis in July. The long-term average end-of-month water surface elevation increase during dry years would average 0.3 feet in July, representing up to a 0.03 percent increase, as

compared to the Baseline Condition. The decreases during dry years in the long-term average end-of-month water surface elevation would occur in 9 of the 16 years included in the analysis in July, in 10 of the 16 years included in the analysis in August, and in 3 of the 16 years in the analysis in September. The long-term average end-of-month water surface elevation decrease during dry years would be up to 1 foot in July and August, and 0.1 foot in September, representing a 0.02 to 0.11 percent decrease, as compared to the Baseline Condition [Appendix H, p. 1001].

Under the Flexible Purchase Alternative, the end-of-month water surface elevation in Lake Shasta during below normal years would be essentially equivalent to or greater than the Baseline Condition for 153 months of the 168 months included in the analysis. During below normal years, the long-term average end-of-month water surface elevation in Lake Shasta would not decrease or increase in any month of the year except during July through September. The increases would occur in 2 of the 14 years included in the analysis in July, August, and September. The long-term average end-of-month water surface elevation increase during below normal years would range from 0.3 feet in July to 0.7 foot in August, representing a 0.03 percent and 0.07 percent increase, respectively, as compared to the Baseline Condition. The decreases during below normal years in the long-term average end-of-month water surface elevation would occur in 6 of the 14 years included in the analysis in July and August, and in 3 of the 14 years included in the analysis in September. The long-term average end-of-month water surface elevation decrease during below normal years would be up to 1.3 feet in both July and August, and 0.1 feet for September, representing a 0.13 percent decrease in July, a 0.07 percent decrease in August and a 0.01 percent decrease in September as compared to the Baseline Condition [Appendix H, p. 1001].

Additionally, long-term average end-of-month storage in Lake Shasta would remain essentially equivalent under the Flexible Purchase Alternative relative to the Baseline Condition. The long-term average end-of-month storage in Lake Shasta would not decrease by more than 0.6 percent in July, August, and September. Long-term average end-of-month storage would decrease by 0.6 percent in July and 0.4 percent in August (Table G-2). Under the Flexible Purchase Alternative, the end-of-month storage in Lake Shasta would be essentially equivalent to or greater than the Baseline Condition for 827 months of the 864 months included in the analysis. In Lake Shasta, hydrologic conditions under the Flexible Purchase Alternative would result in reductions in the end-of-month storage in the months of July and August. Reductions in the end-of-month storage would range from 5.9 percent in July to 4.3 percent in August [Appendix H, p. 97 to 108].

Under the Flexible Purchase Alternative, the end-of-month storage in Lake Shasta during critical years would be essentially equivalent to or greater than the Baseline Condition for 106 months of the 132 months included in the analysis. Within critical years, the long-term average end-of-month storage in Lake Shasta would not increase or decrease during any months of the year except during July through September. Within critical years, the long-term average end-of-month storage in Lake Shasta would increase in 2 of the 11 years included in the analysis in July and in 1 of the 11

years included in the analysis in September. The long-term average end-of-month storage increase during critical years would range from 4.4 thousand acre-feet (TAF) in July to 0.5 TAF in September, representing a 0.44 percent and 0.03 percent increase, respectively, as compared to the Baseline Condition. Decreases within critical years would occur in 9 of the 11 years included in the analysis in July, in 11 of the 11 years included in the analysis in August, and in 6 of the 11 years included in the analysis in September. The long-term average end-of-month storage decrease during critical years would range from 28 TAF in July to 0.5 TAF in September, representing a 2.6 percent to 0.06 percent decrease during that period, as compared to the Baseline Condition [Appendix H, p. 1000].

[1] Based on 72 years modeled.
[2] Relative difference of the monthly long-term average
Note: For a further description of the methodology used for the data assessment, please refer to Section 5.2.1 Assessment Methods.

Under the Flexible Purchase Alternative, the end-of-month storage in Lake Shasta during dry years would be essentially equivalent to or greater than the Baseline Condition for 170 months of the 192 months included in the analysis. Within dry years, the long-term average end-of-month storage in Lake Shasta would not decrease or increase in any month of the year except during July through September. The increases would occur in 1 of the 16 years included in the analysis in July. The long-term average end-of-month storage increase during dry years would average 5 TAF in July, representing a 0.2 percent increase, as compared to the Baseline Condition. The decreases during dry years in the long-term average end-of-month storage would occur in 9 of the 16 years included in the analysis in July, in 10 of the 16 years included in the analysis in August, and in 3 of the 16 years included in the analysis in September. The long-term average end-of-month storage decrease during dry years would range from 15 TAF in July to 2 TAF in September, representing a 0.9 percent to 0.2 percent decrease during that period, as compared to the Baseline Condition [Appendix H, p. 1000].

Under the Flexible Purchase Alternative, the end-of-month storage in Lake Shasta during below normal years would be essentially equivalent to or greater than the Baseline Condition for 153 months of the 168 months included in the analysis. During below normal years, the long-term average end-of-month storage in Lake Shasta would not decrease or increase in any month of the year except during July through September. Increases would occur in 2 of the 14 years included in the analysis in each of July, August and September. The long-term average end-of-month storage increase during below normal years would range from 14 TAF in August to 0.4 TAF in September, representing up to a 0.6 increase during July through September, as compared to the Baseline Condition. The decreases during below normal years in the long-term average end-of-month storage would occur in 6 of the 14 years included in the analysis in July and August, and in 3 of the 14 years included in the analysis in September. The long-term average end-of-month storage decrease during below normal years would range from 30 TAF in July to 1 TAF in September, representing a 1 percent to 0.05 percent decrease, during that period, as compared to the Baseline Condition [Appendix H, p. 1000].

Overall, Lake Shasta end-of-month water surface elevation and reservoir storage under the Flexible Purchase Alternative would be essentially equivalent to or greater than end-of-month water surface elevation and reservoir storage under the Baseline Condition. Additionally, end-of-month water surface elevation under the Flexible Purchase Alternative would be essentially equivalent to or greater than the end-of-month water surface elevation under the Baseline Condition in 831 months of the 864 months analyzed, and end-of-month storage under the Flexible Purchase Alternative would be essentially equivalent to or greater than the end-of-month storage under the Baseline Condition in 827 months of the 864 months analyzed. Therefore, implementation of the Flexible Purchase Alternative would not be expected to adversely affect concentrations of water quality constituents or water temperatures in Lake Shasta. As a result, any differences in water surface elevation and reservoir storage would not be expected to be of sufficient magnitude and frequency to affect water quality in such a way that would result in long-term adverse effects to designated beneficial uses, exceedance of existing regulatory standards or substantial degradation of water quality. Consequently, potential effects to water quality in Lake Shasta would be considered less than significant.

Lake Oroville

EWA acquisition of Feather River contractor water via stored reservoir water, groundwater substitution and crop idling under the Flexible Purchase Alternative would alter surface water elevations or reservoir storage in Lake Oroville, relative to the Baseline Condition.

Under the Flexible Purchase Alternative, the long-term average end-of-month water surface elevation in Lake Oroville would remain essentially equivalent to or greater than the Baseline Condition during most months of the year (Table G-3). In fact, the long-term average end-of-month water surface elevation in Lake Oroville would increase in May and June. Long-term average end-of-month water surface elevation would increase by 0.2 percent in May and 0.4 percent in June (Table G-3). Under the

Flexible Purchase Alternative, the end-of-month water surface elevation in Lake Oroville would be essentially equivalent to or greater than the Baseline Condition for 762 months of the 864 months included in the analysis. In Lake Oroville, hydrologic conditions under the Flexible Purchase Alternative would result in reductions in the end-of-month water surface elevation in the months of July and August. Reductions in the end-of-month water surface elevation would range from 17 feet in July to 10 feet in August [Appendix H, p. 580-591].

Table G-3
Lake Oroville End-of-Month Elevation Under the Baseline Condition and Flexible Purchase Alternative

Month	Average Elevation[1] (feet msl)

Nov	780	780	0
Dec	791	791	0

[1] During 72 years modeled.
Note: For a further description of the methodology used for the data assessment, please refer to Section 5.2.1, Assessment Methods.

Under the Flexible Purchase Alternative, the end-of-month water surface elevation in Lake Oroville during critical years would be essentially equivalent to or greater than the Baseline Condition for 110 months of the 132 months included in the analysis. During critical years, the long-term average end-of-month water surface elevation in Lake Oroville would not decrease or increase in any month of the year except during May through September. Within critical years, the long-term average end-of-month water surface elevation in Lake Oroville would increase in 11 of the 11 years included in the analysis in May and June, in 5 of the 11 years included in the analysis in July, and in 3 of the 11 years in the analysis in September. The long-term average end-of-month water surface elevation increase during critical years would be up to 5 feet in May, 10 feet in June, 5 feet in July, and 0.1 feet in September, representing 0.6 percent, 1.3 percent, 0.7 percent, and 0.02 percent increase, respectively, as compared to the Baseline Condition. The decreases during critical years in the long-term average end-of-month water surface elevation would occur in 6 of the 11 years included in the analysis in July, in 11 of the 11 years included in the analysis in August, and in 5 of the 11 years included in the analysis in September. The long-term average end-of-month water surface elevation decrease during critical years would range from 7 feet in July to 1 foot in September, representing a 1 percent to 0.2 percent decrease during that period, as compared to the Baseline Condition [Appendix H, p. 1005].

Under the Flexible Purchase Alternative, the end-of-month water surface elevation in Lake Oroville during dry years would be essentially equivalent to or greater than the Baseline Condition for 162 months of the 192 months included in the analysis. Within dry years, the long-term average end-of-month water surface elevation in Lake Oroville would not decrease or increase in any month of the year except May through September. The increases would occur in 10 of the 16 years included in the analysis in May and June, in 6 of the 16 years included in the analysis in July, and in 3 of the 16 years included in the analysis in September. The long-term average end-of-month water surface elevation increase during dry years would be up to 3 feet in May, 6 feet in June, 5 feet in July, and 0.1 feet in September, representing a 0.3 percent, 0.7 percent, 0.6 percent, and 0.01 percent increase, respectively, as compared to the Baseline Condition. The decreases during dry years in the long-term average end-of-month water surface elevation would occur in 10 of the 16 years included in the analysis in July, in 16 of the 16 years included in the analysis in August and in 4 of the 16 years included in the analysis in September. The long-term average end-of-month water surface elevation decrease during dry years would range from 5 feet in July, to 0.4 feet in September, representing a 0.6 percent to 0.06 percent decrease during that period, as compared to the Baseline Condition [Appendix H, p. 1005].

Under the Flexible Purchase Alternative, the end-of-month water surface elevation in Lake Oroville during below normal years would be essentially equivalent to or greater than the Baseline Condition for 134 months of the 168 months included in the analysis. During below normal years, the long-term average end-of-month water surface elevation in Lake Oroville would not decrease or increase in any month of the year except during May through September. The increases would occur in 6 of the 14 years included in the analysis in May and in 7 of the 14 years included in the analysis in June. The long-term average end-of-month water surface elevation increase during below normal years would range from 1 foot in May to 3 feet in June, representing a 0.2 percent and 0.3 percent increase, respectively, as compared to the Baseline Condition. The decreases during below normal years in the long-term average end-of-month water surface elevation would occur in 14 of the 14 years included in the analysis in July, in 11 of the 14 years included in the analysis in August, and in 7 of the 14 years included in the analysis in September. The long-term average end-of-month water surface elevation decrease during below normal years would range from 4 feet in July to 0.3 feet in September, representing a 0.5 percent to 0.04 percent decrease, during that period, as compared to the Baseline Condition [Appendix H, p. 1005].

Long-term average end-of-month storage in Lake Oroville under the Flexible Purchase Alternative would remain essentially equivalent to or greater than the Baseline Condition during most months of the year. The long-term average end-of-month storage in Lake Oroville would increase in May and June and decrease in July, August, and September. Long-term average end-of-month storage would increase by 0.6 percent in May and 1.4 percent in June and decrease by 2.0 percent in July, 1.2 percent in August, and 0.1 percent in September (Table G-4). Under the Flexible Purchase Alternative, the end-of-month storage in Lake Oroville would be essentially

equivalent to or greater than the Baseline Condition for 771 months of the 864 months included in the analysis. In Lake Oroville, hydrologic conditions under the Flexible Purchase Alternative would result in reductions in the end-of-month storage in the months of July, August, and September. Reductions in the end-of-month storage would be 9.3 percent in July, 6.1 percent in August, and 4.1 percent in September [Appendix H, p. 121-132].

Under the Flexible Purchase Alternative, the end-of-month storage in Lake Oroville during critical years would be essentially equivalent to or greater than the Baseline Condition for 110 months of the 132 months included in the analysis. Within critical years, the long-term average end-of-month storage in Lake Oroville would not decrease or increase in any month of the year except during May through September. Within critical years, the long-term average end-of-month storage in Lake Oroville would increase in 11 of the 11 years included in the analysis in May and June, in 5 of the 11 years included in the analysis in July, and in 3 of the 11 years included in the analysis in September. The long-term average end-of-month storage increase during critical years would range from 43 TAF in May, 92 TAF in June, 41 TAF in July, to 1 TAF in September, representing a 2.4 percent, 6.0 percent, 2.6 percent, and 0.1 percent increase, respectively, as compared to the Baseline Condition. The decreases during critical years in the long-term average end-of-month storage would occur in 6 of the 11 years included in the analysis in July, in 11 of the 11 years included in the analysis in August, and in 5 of the 11 years included in the analysis in September. The long-term average end-of-month storage decrease during critical years would range from 52 TAF in July to 3 TAF in September, representing a 4 percent to 1 percent decrease, during that period, as compared to the Baseline Condition [Appendix H, p. 1004].

Table G-4
Long-term Average Lake Oroville End of Month Storage Under the Baseline Condition and Flexible Purchase Alternative

[1] Based on 72 years modeled.
[2] Relative difference of the monthly long-term average.
Note: For a further description of the methodology used for the data assessment, please refer to Section 5.2.1 Assessment Methods.

Under the Flexible Purchase Alternative, the end-of-month storage in Lake Oroville during dry years would be essentially equivalent to or greater than the Baseline Condition for 158 months of the 192 months included in the analysis. Within dry years, the long-term average end-of-month storage in Lake Oroville would not decrease or increase in any month of the year except during May through September. The increases would occur in 10 of the 16 years included in the analysis in May and June, in 6 of the 16 years included in the analysis in July, and in 3 of the 16 years included in the analysis in September. The long-term average end-of-month storage increase during dry years would range from 37 TAF in May, 77 TAF in June, 52 TAF in July, to 1 TAF in September, representing a 1.4 percent, 3.1 percent, 2.5 percent, and 0.1 percent increase, respectively, as compared to the Baseline Condition. The decreases during dry years in the long-term average end-of-month storage would occur in 10 of the 16 years included in the analysis in July, in 16 of the 16 years included in the analysis in August, and in 4 of the 16 years included in the analysis in September. The long-term average end-of-month storage decrease during dry years would range from 50 TAF in July to 4 TAF in September, representing a 2.3 percent to 0.3 percent decrease, during that period, as compared to the Baseline Condition [Appendix H, p. 1004].

Under the Flexible Purchase Alternative, the end-of-month storage in Lake Oroville during below normal years would be essentially equivalent to or greater than the Baseline Condition for 136 months of the 168 months included in the analysis. During below normal years, the long-term average end-of-month storage in Lake Oroville would not decrease or increase in any month of the year except during May through September. The increases would occur in 6 of the 14 years included in the analysis in May and in 7 of the 14 years included in the analysis in June. The long-term average end-of-storage increase during below normal years would range from 20 TAF in May to 40 TAF in June, representing a 0.6 percent and 1.3 percent increase, respectively, as compared to the Baseline Condition. The decreases during below normal years in the long-term average end-of-month storage would occur in 14 of the 14 years included in the analysis in July and 11 of the 14 years included in the analysis in August and in 7 of the 14 years included in the analysis in September. The long-term average end-of-month storage decrease during below normal years would range from 53 TAF in July to 3 TAF in September, representing a 2.1 percent to 0.2 percent decrease, during that period, as compared to the Baseline Condition [Appendix H, p. 1004].

Overall, Lake Oroville end-of-month water surface elevation and reservoir storage under the Flexible Purchase Alternative would not be substantially less than end-of-month water surface elevation and reservoir storage under the Baseline Condition. Additionally, end-of-month water surface elevation under the Flexible Purchase Alternative would be essentially equivalent to or greater than the end-of-month water surface elevation under the Baseline Condition in 762 months of the 864 months analyzed, and end-of-month storage under the Flexible Purchase Alternative would be essentially equivalent to or greater than the end-of-month storage under the Baseline Condition in 771 months of the 864 months analyzed. Therefore, implementation of the Flexible Purchase Alternative would not be expected to

adversely affect concentrations of water quality constituents or water temperatures in Lake Oroville. As a result, any differences in water surface elevation and reservoir storage would not be expected to be of sufficient magnitude and frequency to affect water quality in such as way that would result in long-term adverse effects to designated beneficial uses, exceedance of existing regulatory standards or substantial degradation of water quality. Consequently, potential effects to water quality would be considered less than significant.

Folsom Reservoir

EWA acquisition of American River contractor water via stored reservoir water, groundwater substitution and crop idling under the Flexible Purchase Alternative would alter surface water elevation and reservoir storage in Folsom Reservoir, relative to the Baseline Condition.

Under the Flexible Purchase Alternative, the long-term average end-of-month water surface elevation in Folsom Reservoir would remain essentially equivalent to the Baseline Condition during every month of the year. Long-term average end-of-month water surface elevation would decrease by 1 foot in July and 1 foot in August (Table G-5). Under the Flexible Purchase Alternative, the end-of-month water surface elevation in Folsom Reservoir would be essentially equivalent to or greater than the Baseline Condition for 863 months of the 864 months included in the analysis. In Folsom Reservoir, hydrologic conditions under the Flexible Purchase Alternative would result in reductions in the end-of-month water surface elevation in the month of July. The greatest reductions in the end-of-month water surface elevation would be 2 feet in July [Appendix H, p. 193-204].

Table G-5
Long-term Average Folsom Reservoir End-of-Month Elevation Under the Baseline Condition and Flexible Purchase Alternative

	Average Elevation[1] (feet msl)		
Month	***Baseline Condition***	***Flexible Purchase Alternative***	***Difference***

Dec	408	408	0

[1] Based on 72 years modeled.
Note: For a further description of the methodology used for the data assessment, please refer to Section 5.2.1 Assessment Methods.

Under the Flexible Purchase Alternative, the end-of-month water surface elevation in Folsom Reservoir during critical years would be essentially equivalent to or greater than the Baseline Condition for 110 months of the 132 months included in the analysis. During critical years, the long-term average end-of-month water surface elevation in Folsom Reservoir would not increase during any month of the year and would decrease during July and August. Within critical years, the long-term average end-of-month water surface elevation in Folsom Reservoir would decrease in 11 of the 11 years included in the analysis in July and in August. The long-term average end-of-month water surface elevation decrease during critical years would be 1 foot in July and in August, representing a 0.2 percent decrease, each, as compared to the Baseline Condition [Appendix H, p. 1003].

Under the Flexible Purchase Alternative, the end-of-month water surface elevation in Folsom Reservoir during dry years would be essentially equivalent to or greater than the Baseline Condition for 160 months of the 192 months included in the analysis. Within dry years, the long-term average end-of-month water surface elevation in Folsom Reservoir would not increase in any month of the year and would decrease during July and August. The decreases would occur in 16 of the 16 years included in the analysis in July and in August. The long-term average end-of-month water surface elevation decrease during dry years would be 0.3 feet in July and 0.4 feet in August, representing a 0.1 percent decrease each, as compared to the Baseline Condition [Appendix H, p. 1003].

Under the Flexible Purchase Alternative, the end-of-month water surface elevation in Folsom Reservoir during below normal years would be essentially equivalent to or greater than the Baseline Condition for 140 months of the 168 months included in the analysis. During below normal years, the long-term average end-of-month water surface elevation in Folsom Reservoir would not increase in any month of the year and would decrease during July and August. The decreases would occur in 14 of the 14 years included in the analysis in July and in August. The long-term average end-of-month water surface elevation decrease during below normal years would be 0.4 feet in July and in August, representing a 0.1 percent decrease each, as compared to the Baseline Condition [Appendix H, p. 1003].

Additionally, long-term average end-of-month storage in Folsom Reservoir would remain essentially equivalent under the Flexible Purchase Alternative relative to the Baseline Condition. Long-term average end-of-month storage would decrease by 0.6 percent in July and 0.5 percent in August (Table G-6). Under the Flexible Purchase Alternative, the end-of-month storage in Folsom Reservoir would be essentially equivalent to or greater than the Baseline Condition for 851 months of the 864 months included in the analysis. In Folsom Reservoir, hydrologic conditions under the Flexible Purchase Alternative would result in reductions in the end-of-month storage from the months of July and August. Reductions in the end-of-month storage would range from 6 feet in July to 4 feet in August [Appendix H, p. 109-120].

Table G-6
Long-term Average Folsom Reservoir End-of-Month Storage
Under the Baseline Condition and Flexible Purchase Alternative

Dec	457	457	0	0.0

[1] Based on 72 years modeled.
[2] Relative difference of the monthly long-term average.
Note: For a further description of the methodology used for the data assessment, please refer to Section 5.2.1 Assessment Methods.

Under the Flexible Purchase Alternative, the end-of-month storage in Folsom Reservoir during critical years would be essentially equivalent to or greater than the Baseline Condition for 110 months of the 132 months included in the analysis. Within critical years, the long-term average end-of-month storage in Folsom Reservoir would not increase in any month of the year and would decrease during July and August. Within critical years, the long-term average end-of-month storage in Folsom Reservoir would decrease in 11 of the 11 years included in the analysis in July and in August. The long-term average end-of-month storage decrease during critical years would be 3 TAF in July and in August, representing a 1 percent decrease each, as compared to the Baseline Condition [Appendix H, p. 1002].

Under the Flexible Purchase Alternative, the end-of-month storage in Folsom Reservoir during dry years would be essentially equivalent to or greater than the Baseline Condition for 160 months of the 192 months included in the analysis. Within dry years, the long-term average end-of-month storage in Folsom Reservoir would not increase in any month of the year and would decrease during July and August. The decreases would occur in 16 of the 16 years included in the analysis in July and in August. The long-term average end-of-month storage decrease during dry years would be 2 TAF in July and 3 TAF in August, representing a 0.5 percent and 0.8 percent decrease, respectively, as compared to the Baseline Condition [Appendix H, p. 1002].

Under the Flexible Purchase Alternative, the end-of-month storage in Folsom Reservoir during below normal years would be essentially equivalent to or greater than the Baseline Condition for 140 months of the 168 months included in the analysis. During below normal years, the long-term average end-of-month storage in Folsom Reservoir would not increase in any month of the year and would decrease during July and August. The decreases would occur in 14 of the 14 years included in

the analysis in July and in August. The long-term average end-of-month decrease during below normal years would be 4 TAF in July and 3 TAF in August, representing a 0.6 percent decrease each, as compared to the Baseline Condition [Appendix H, p. 1002].

Overall, Folsom Reservoir end-of-month water surface elevation and reservoir storage under the Flexible Purchase Alternative would be essentially equivalent to or greater than end-of-month water surface elevation and reservoir storage under the Baseline Condition. Additionally, end-of-month water surface elevation under the Flexible Purchase Alternative would be essentially equivalent to or great than the end-of-month water surface elevation under the Baseline Condition in 863 months of the 864 months analyzed, and end-of-month storage under the Flexible Purchase Alternative would be essentially equivalent to or great than the end-of-month storage under the Baseline Condition in 851 months of the 864 months analyzed. Therefore, implementation of the Flexible Purchase Alternative would not be expected to adversely affect concentrations of water quality constituents or water temperatures in Folsom Reservoir. As a result, any differences in water surface elevation and reservoir storage would not be expected to be of sufficient magnitude and frequency to affect water quality in such as way that would result in long-term adverse effects to designated beneficial uses, exceedance of existing regulatory standards or substantial degradation of water quality. Consequently, potential effects to water quality would be considered less than significant.

1.5.1.2 Non-Project Reservoirs Within the Upstream from the Delta Region

Little Grass Valley and Sly Creek Reservoirs

EWA acquisition of OWID stored reservoir water would reduce surface water elevation and reservoir storage in Little Grass Valley and Sly Creek reservoirs, relative to the Baseline Condition.

Table G-7 provides monthly median reservoir storage and water surface elevation for Little Grass Valley Reservoirs. In Little Grass Valley Reservoir, hydrologic conditions under the Flexible Purchase Alternative would result in reduction of median reservoir storage for the months of November through April as compared to the Baseline Condition. Reductions in median reservoir storage would range from 3 percent in April to 24 percent in December under the Flexible Purchase Alternative relative to the Baseline Condition. Hydrologic conditions under the Flexible Purchase Alternative would result in reduction of the median water surface elevation for the months of November through April as compared to the Baseline Condition. Reductions in median water surface elevation would range from 2 feet in April to 12 feet in December under the Flexible Purchase Alternative relative to the Baseline Condition.

Table G-7
Little Grass Valley Reservoir Monthly Median Storage, and Water Surface Elevation Under the Baseline Condition and Flexible Purchase Alternative

	Storage				Elevation

Sep	58	58	0	0	5023	5023	0

Based on median monthly storage and flow over the historical record from 1970 to 2001.
Note: For a further description of the methodology used for the data assessment, please refer to Section 5.2.1 Assessment Methods.

The monthly median storage and water surface elevation for Little Grass Valley Reservoir during critical and dry and below normal years are provided in Tables G-8 and G-9, respectively. In Little Grass Valley Reservoir, hydrologic conditions under the Flexible Purchase Alternative during critical years would result in reduction of median reservoir storage from the months of November through April as compared to the Baseline Condition. Reductions in median reservoir storage during critical years would range from 3 percent in April to 24 percent in December under the Flexible Purchase Alternative relative to the Baseline Condition. Hydrologic conditions under the Flexible Purchase Alternative during critical years would result in reduction of the median water surface elevation from the months of November through April as compared to the Baseline Condition. Reductions in median water surface elevation during critical years would range from 2 feet in April to 12 feet in December under the Flexible Purchase Alternative relative to the Baseline Condition.

Based on median monthly storage and flow over the historical record from 1970 to 2001. Note: For a further description of the methodology used for the data assessment, please refer to Section 5.2.1 Assessment Methods.

Hydrologic conditions under the Flexible Purchase Alternative during dry and below normal years would result in reduction of median reservoir storage from the months of November through April as compared to the Baseline Condition. Reductions in median reservoir storage during dry and below normal years would range from 3 percent in April to 24 percent in December under the Flexible Purchase Alternative relative to the Baseline Condition. Hydrologic conditions under the Flexible Purchase Alternative during dry and below normal years would result in reduction of the median water surface elevation for the months of November through April as

compared to the Baseline Condition. Reductions in median water surface elevation during dry and below normal years would range from 2 feet in April to 12 feet in December under the Flexible Purchase Alternative relative to the Baseline Condition.

In Sly Creek Reservoir, hydrologic conditions under the Flexible Purchase Alternative would result in reduction of median reservoir storage from the months of November through April as compared to the Baseline Condition (Table G-10). Reductions in median reservoir storage would range from 2 percent in April to 27 percent in December under the Flexible Purchase Alternative relative to the Baseline Condition. Hydrologic conditions under the Flexible Purchase Alternative would result in reduction of the median water surface elevation from the months of November through April as compared to the Baseline Condition. Reductions in median water surface elevation would range from 2 feet in April to 18 feet in December under the Flexible Purchase Alternative relative to the Baseline Condition.

Based on median monthly storage and flow over the historical record from 1970 to 2001. Note: For a further description of the methodology used for the data assessment, please refer to Section 5.2.1 Assessment Methods.

Hydrologic conditions under the Flexible Purchase Alternative during dry and below normal years would result in reduction of median reservoir storage for the months of November through April as compared to the Baseline Condition. Reductions in median reservoir storage during dry and below normal years would range from 2 percent in April to 27 percent in December under the Flexible Purchase Alternative relative to the Baseline Condition. Hydrologic conditions under the Flexible Purchase Alternative during dry and below normal years would result in reduction of the median water surface elevation for the months of November through April as compared to the Baseline Condition. Reductions in median water surface elevation

during dry and below normal years would range from 2 feet in April to 21 feet in December under the Flexible Purchase Alternative relative to the Baseline Condition.

Overall, median water surface elevation and median reservoir storage under the Flexible Purchase Alternative would be decreased from November to April as compared to the Baseline Condition. Water temperatures during these months of the year would be expected to be at their lowest points during the annual cycle, and therefore the decrease in median reservoir storage and water surface elevation would not be expected to cause an increase in water temperature that would affect overall reservoir water quality. Additionally, because of the high quality of the water flowing into these reservoirs, the decrease in median reservoir storage and water surface elevation would not be expected to cause an increase in concentrations of water quality constituents that would affect overall reservoir water quality. As a result, any differences in median water surface elevation and reservoir storage would not be expected to be of sufficient magnitude and frequency to affect long-term water quality in such a way that would result in adverse effects to designated beneficial uses, exceedance of existing regulatory standards or substantial degradation of water quality. Consequently, potential effects to water quality would be considered less than significant.

New Bullards Bar Reservoir

EWA acquisition of Yuba County Water Agency via stored reservoir water and groundwater substitution would alter surface water elevation and reservoir storage in New Bullards Bar Reservoir, relative to the Baseline Condition.

Table G-13 provides monthly median reservoir storage and water surface elevation for New Bullards Bar Reservoir. In New Bullards Bar Reservoir, hydrologic conditions under the Flexible Purchase Alternative would result in reduction of median reservoir storage from the months of July through January as compared to the Baseline Condition. Reductions in median reservoir storage would range from 1 percent in July to 18 percent in October and November under the Flexible Purchase Alternative relative to the Baseline Condition. Additionally, median reservoir storage would increase by up to 5 percent between April and June. Hydrologic conditions under the Flexible Purchase Alternative would result in reduction of the median water surface elevation from the months of July through January as compared to the Baseline Condition. Reductions in median water surface elevation would range from 1 foot in July to 27 feet in October under the Flexible Purchase Alternative relative to the Baseline Condition. Additionally, median water surface elevation would increase by up to 5 feet between April and June.

Based on median monthly storage and flow over the historical record from 1970 to 2001. Note: For a further description of the methodology used for the data assessment, please refer to Section 5.2.1 Assessment Methods.

Monthly median reservoir storage and water surface elevation for New Bullards Bar Reservoir during critical and dry and below normal years are provided in Table G-14 and Table G-15, respectively. In New Bullards Bar Reservoir, hydrologic conditions under the Flexible Purchase Alternative during critical years would result in reduction of median reservoir storage from the months of July through December as compared to the Baseline Condition. Reductions in median reservoir storage during critical years would range from 0.8 percent in July to 19 percent in September under the Flexible Purchase Alternative relative to the Baseline Condition. Additionally, median reservoir storage during critical years would increase by up to 7 percent in June. Hydrologic conditions under the Flexible Purchase Alternative during critical years would result in reduction of the median water surface elevation from the months of July through December as compared to the Baseline Condition. Reductions in median water surface elevation during critical years would range from 1 foot in July to 28 feet in September under the Flexible Purchase Alternative relative to the Baseline Condition. Additionally, median water surface elevation during critical years would increase by up to 8 feet in June.

Hydrologic conditions under the Flexible Purchase Alternative during dry and below normal years would result in reduction of median reservoir storage from the months of July through January as compared to the Baseline Condition. Reductions in median reservoir storage during dry and below normal years would range from 0.6 percent in July to 17 percent in September under the Flexible Purchase Alternative relative to the Baseline Condition. Additionally, median reservoir storage during dry and below normal years would increase by up to 5 percent in June. Hydrologic conditions under the Flexible Purchase Alternative during dry and below normal years would result in reduction of the median water surface elevation from the months of July through January as compared to the Baseline Condition. Reductions

in median water surface elevation during dry and below normal years would range from 1 foot in July to 25 feet in September under the Flexible Purchase Alternative relative to the Baseline Condition. Additionally, median water surface elevation during dry and below normal years would increase by up to 6 feet in June.

Aug	648	596	-52	-8	1862	1851	-11
Sep	595	495	-100	-17	1850	1826	-25

Based on median monthly storage and flow over the historical record from 1970 to 2001 Note: For a further description of the methodology used for the data assessment, please refer to Section 5.2.1 Assessment Methods.

Overall, median water surface elevation and median reservoir storage under the Flexible Purchase Alternative would be decreased from July to January, but would increase from April through June as compared to the Baseline Condition. Water temperatures during the months of greatest reductions (September through

December) would be expected to be low enough that the decrease in median reservoir storage and water surface elevation would not cause an increase in water temperature that would affect overall reservoir water quality. Additionally, because of the high quality of the water flowing into this reservoir, the decrease in median reservoir storage and water surface elevation would not be expected to cause an increase in concentrations of water quality constituents that would affect overall reservoir water quality. As a result, any differences in median water surface elevation and reservoir storage would not be expected to be of sufficient magnitude and frequency to affect long-term water quality in such as way that would result in adverse effects to designated beneficial uses, exceedance of existing regulatory standards or substantial degradation of water quality. Consequently, potential effects to water quality would be considered less than significant.

French Meadows and Hell Hole Reservoirs

EWA acquisition of Placer County Water Agency-stored reservoir water would decrease surface water elevation and reservoir storage in French Meadows and Hell Hole reservoirs, relative to the Baseline Condition.

Table G-16 provides monthly median reservoir storage and water surface elevation for French Meadows Reservoir. In French Meadows Reservoir, hydrologic conditions under the Flexible Purchase Alternative would result in reduction of median reservoir storage from the months of July through January as compared to the Baseline Condition. Reductions in median reservoir storage would range from 2 percent in July to 12 percent in October under the Flexible Purchase Alternative relative to the Baseline Condition. Hydrologic conditions under the Flexible Purchase Alternative would result in reduction of the median water surface elevation from the months of July through January as compared to the Baseline Condition. Reductions in median water surface elevation would range from 2 feet in July to 8 feet in October under the Flexible Purchase Alternative relative to the Baseline Condition.

Table G-16

Based on median monthly storage and flow over the historical record from 1974 to 2001 with a maximum 20 TAF EWA Action on French Meadows and Hell Hole Reservoirs combined.
Note: For a further description of the methodology used for the data assessment, please refer to Section 5.2.1 Assessment Methods.

Monthly median reservoir storage and water surface elevation for French Meadows during critical and dry and below normal years are provided in Table G-17 and Table G-18, respectively. In French Meadows Reservoir, hydrologic conditions under the Flexible Purchase Alternative during critical years would result in reduction of median reservoir storage during the months of July through October as compared to the Baseline Condition. Reductions in median reservoir storage during critical years would range from 4 percent in July to 19 percent in September under the Flexible Purchase Alternative relative to the Baseline Condition. Hydrologic conditions under the Flexible Purchase Alternative during critical years would result in reduction of the median water surface elevation from the months of July through October as compared to the Baseline Condition. Reductions in median water surface elevation during critical years would range from 2 feet in October to 11 feet in September under the Flexible Purchase Alternative relative to the Baseline Condition.

Sep	80	72	-8	-10	5218	5211	-7	437	481	44	10.0

Based on median monthly storage and flow over the historical record from 1974 to 2001 with a maximum 20 TAF EWA Action on French Meadows and Hell Hole Reservoirs combined.
Note: For a further description of the methodology used for the data assessment, please refer to Section 5.2.1 Assessment Methods.

Hydrologic conditions under the Flexible Purchase Alternative during dry and below normal years would result in reduction of median reservoir storage from the months of July through October as compared to the Baseline Condition. Reductions in median reservoir storage during dry and below normal years would range from 3 percent in July to 12 percent in October under the Flexible Purchase Alternative

relative to the Baseline Condition. Hydrologic conditions under the Flexible Purchase Alternative during dry and below normal years would result in reduction of the median water surface elevation from the months of July through October as compared to the Baseline Condition. Reductions in median water surface elevation during dry and below normal years would range from 2 feet in July to 8 feet in October under the Flexible Purchase Alternative relative to the Baseline Condition.

In Hell Hole Reservoir, hydrologic conditions under the Flexible Purchase Alternative would result in reduction of median reservoir storage from the months of June through January as compared to the Baseline Condition (Table G-19). Reductions in median reservoir storage would range from 2 percent in June to 10 percent in September and October under the Flexible Purchase Alternative relative to the Baseline Condition. Hydrologic conditions under the Flexible Purchase Alternative would result in reduction of the median water surface elevation from the months of June through January as compared to the Baseline Condition. Reductions in median water surface elevation would range from 5 feet in June to 15 feet in September and October under the Flexible Purchase Alternative relative to the Baseline Condition.

Based on median monthly storage and flow over the historical record from 1974 to 2001 with a maximum 20 TAF EWA Action on French Meadows and Hell Hole Reservoirs combined. Note: For a further description of the methodology used for the data assessment, please refer to Section 5.2.1 Assessment Methods.

Monthly median reservoir storage and water surface elevation for Hell Hole during critical and dry and below normal years are provided in Table G-20 and Table G-21, respectively. In Hell Hole Reservoir, hydrologic conditions under the Flexible Purchase Alternative during critical years would result in reduction of median reservoir storage from the months of June through October as compared to the Baseline Condition. Reductions in median reservoir storage during critical years would range from 3 percent in June to 13 percent in September under the Flexible Purchase Alternative relative to the Baseline Condition. Hydrologic conditions under the Flexible Purchase Alternative during critical years would result in reduction of the median water surface elevation from the months of June through October as compared to the Baseline Condition. Reductions in median water surface elevation

during critical years would range from 5 feet in June to 18 feet in September under the Flexible Purchase Alternative relative to the Baseline Condition.

Table G-20
Hell Hole Reservoir Monthly Median Storage and Elevation Under the Baseline Condition and Flexible Purchase Alternative During Critical Years

	Storage				Elevation

Jul	143	135	-8	-6	4582	4572	-9
Aug	129	117	-12	-9	4565	4550	-15
Sep	114	102	-12	-11	4547	4531	-16

Based on median monthly storage and flow over the historical record from 1974 to 2001 with a maximum 20 TAF EWA Action on French Meadows and Hell Hole Reservoirs combined. Note: For a further description of the methodology used for the data assessment, please refer to Section 5.2.1 Assessment Methods.

Hydrologic conditions under the Flexible Purchase Alternative during dry and below normal years would result in reduction of median reservoir storage from the months of June through October as compared to the Baseline Condition. Reductions in median reservoir storage during dry and below normal years would range from 2 percent in June to 11 percent in September under the Flexible Purchase Alternative relative to the Baseline Condition. Hydrologic conditions under the Flexible Purchase Alternative during dry and below normal years would result in reduction of the median water surface elevation from the months of June through October as compared to the Baseline Condition. Reductions in median water surface elevation

during dry and below normal years would range from 4 feet in June to 16 feet in September under the Flexible Purchase Alternative relative to the Baseline Condition.

Overall, median water surface elevation and median reservoir storage under the Flexible Purchase Alternative would decrease from June to January in Hell Hole Reservoir and from July to January in French Meadows Reservoir as compared to the Baseline Condition. Water temperatures during the months of greatest reduction (September and October) would be expected to be low enough, given the percentage reduction in median reservoir storage, that the decrease in median reservoir storage and water surface elevation would not be expected to cause an increase in water temperature that would affect overall reservoir water quality. Additionally, because of the high quality of the water flowing into these reservoirs, the decrease in median reservoir storage and water surface elevation would not be expected to cause an increase in concentrations of water quality constituents that would affect overall reservoir water quality. As a result, any differences in median water surface elevation and reservoir storage would not be expected to be of sufficient magnitude and frequency to affect long-term water quality in such as way that would result in adverse effects to designated beneficial uses, exceedance of existing regulatory standards or substantial degradation of water quality. Consequently, potential effects to water quality would be considered less than significant.

Lake McClure

EWA acquisition of Merced Irrigation District (MID) water via groundwater substitution would increase surface water elevation or reservoir storage in Lake McClure, relative to the Baseline Condition.

Table G-22 provides monthly median reservoir storage and water surface elevation for Lake McClure. In Lake McClure, hydrologic conditions under the Flexible Purchase Alternative would result in an increase in median reservoir storage from the months of May through October as compared to the Baseline Condition. Increases in median reservoir storage would range from 1 percent in May and June to 4 percent in September under the Flexible Purchase Alternative relative to the Baseline Condition. Hydrologic conditions under the Flexible Purchase Alternative would result in an increase in the median water surface elevation from the months of May through October as compared to the Baseline Condition. Increases in median water surface elevation would range from 1 foot in June and July to 3 feet in September under the Flexible Purchase Alternative relative to the Baseline Condition. No decreases in median reservoir storage or median water surface elevation would be expected in any month.

Table G-22
Lake McClure Monthly Median Storage and Elevation
Under the Baseline Condition and Flexible Purchase Alternative

	Storage				Elevation		
Month	Baseline Condition (TAF)	FPA (TAF)	Diff (TAF)	Diff (%)	Baseline Condition (ft msl)	FPA (ft msl)	Diff (ft msl)
Oct	598	611	13	2	778	779	2

Sep	615	640	25	4	780	783	3

Based on median monthly storage and flow over the historical record from 1970 to 2001.
Note: For a further description of the methodology used for the data assessment, please refer to Section 5.2.1 Assessment Methods.

Monthly median reservoir storage and water surface elevation for Lake McClure during critical and dry and below normal years are provided in Table G-23 and Table G-24, respectively. In Lake McClure, hydrologic conditions under the Flexible Purchase Alternative during critical years would result in no reductions of median reservoir storage for all months of the year as compared to the Baseline Condition. In fact, increases would occur in the median reservoir storage during the months of April through October. Increases in the median reservoir storage would range from 0.9 percent in April to 17 percent in September. Hydrologic conditions under the Flexible Purchase Alternative during critical years would result in no reductions of the median water surface elevation for all months of the year as compared to the Baseline Condition. Increase in median water surface elevation during critical years would range from 1 foot in April to 13 feet in September under the Flexible Purchase Alternative relative to the Baseline Condition.

Hydrologic conditions under the Flexible Purchase Alternative during dry and below normal years would result in no reductions of median reservoir storage for all months of the year as compared to the Baseline Condition. In fact increase would occur in median reservoir storage during the months of April through October. Increases in median reservoir storage during dry and below normal years would range from 0.4 percent in April to 8 percent in September under the Flexible Purchase Alternative relative to the Baseline Condition. Hydrologic conditions under the Flexible Purchase Alternative during dry and below normal years would result in no reductions of the median water surface elevation for all months of the year as compared to the Baseline Condition. Increase in median water surface elevation during dry and below normal years would range from 3 feet in July to 22 feet in October under the Flexible Purchase Alternative relative to the Baseline Condition.

Table G-23
Lake McClure Monthly Median Storage and Elevation
Under the Baseline Condition and Flexible Purchase Alternative During Critical Years

	Storage				Elevation		
Month	Baseline Condition (TAF)	FPA (TAF)	Diff (TAF)	Diff (%)	Baseline Condition (ft msl)	FPA (ft msl)	Diff (ft msl)

Jun	640	652	13	2	783	784	1
Jul	628	545	18	3.4	768	771	3
Aug	420	442	22	5.2	746	751	5
Sep	314	339	25	8	715	723	8

Based on median monthly storage and flow over the historical record from 1970 to 2001.
Note: For a further description of the methodology used for the data assessment, please refer to Section 5.2.1 Assessment Methods.

Overall, median water surface elevation and median reservoir storage under the Flexible Purchase Alternative would be increased from May to October and would remain essentially equivalent from June through September as compared to the Baseline Condition. Increases in median reservoir storage and median water surface elevation would be expected to benefit the water quality by providing additional water for dilution of constituents and by providing additional water to buffer water temperature increases. As a result, increases in median water surface elevation and reservoir storage would not be expected to be of sufficient magnitude and frequency to affect long-term water quality in such as way that would result in adverse effects to designated beneficial uses, exceedance of existing regulatory standards or substantial

degradation of water quality. Consequently, potential effects to water quality would be considered less than significant.

1.4.1.3 Rivers Within the Upstream from the Delta Region

Sacramento River

EWA acquisition of Sacramento River contractor water via stored reservoir water, groundwater substitution, and crop idling under the Flexible Purchase Alternative would not substantially decrease Sacramento River flow, relative to the Baseline Condition.

The long-term average flow in the Sacramento River below Keswick Dam would decrease by less than 0.8 percent under the Flexible Purchase Alternative, compared to the Baseline Condition, during all months of the year as shown in Table G-25. In fact, long-term average Sacramento River flow below Keswick Dam under the Flexible Purchase Alternative would not decrease in comparison to flows under the Baseline Condition in any month except August and September, when the long-term average decrease in flow would be 0.5 and 0.8 percent, respectively. Long-term average flows would increase by 0.9 percent in July. Further, in 828 out of 864 months simulated, Sacramento River flow below Keswick Dam under the Flexible Purchase Alternative would be essentially equivalent to or greater than flow under the Baseline Condition. The maximum flow reduction in any month would be 6.2 percent [Appendix H, p. 349-360].

Table G-25
Long-term Average Release From Keswick Dam
Under the Baseline Condition and Flexible Purchase Alternative

Month	Monthly Mean Flow[1] (cfs)		Difference	
	Baseline Condition	Flexible Purchase Alternative	(cfs)	(%)[2]
Oct	5842	5842	0	0.0
Nov	4854	4854	0	0.0
Dec	6672	6672	0	0.0
Jan	7951	7951	0	0.0
Feb	10,056	10,056	0	0.0
Mar	8249	8249	0	0.0
Apr	7706	7706	0	0.0
May	8381	8381	0	0.0
Jun	10,529	10,529	0	0.0
Jul	13,284	13,398	114	0.9
Aug	10,556	10,498	-58	-0.5
Sep	7278	7222	-56	-0.8

[1] Based on 72 years modeled.
[2] Relative difference of the monthly long-term average.
Note: For a further description of the methodology used for the data assessment, please refer to Section 5.2.1 Assessment Methods.

Under the Flexible Purchase Alternative, the long-term average flow in the Sacramento River below Keswick Dam during critical years would be essentially equivalent to or greater than the Baseline Condition for 113 months of the 132 months included in the analysis. Within critical years, the long-term average flow in the Sacramento River below Keswick Dam would decrease in 8 of the 11 years included

in the analysis in August and in 11 of the 11 years included in the analysis in September. The long-term average flow decrease during critical years would average 170 cfs in August and 187 cfs in September, representing a 2.0 percent decrease in August and a 3.5 percent decrease in September compared to the Baseline Condition [Appendix H, p. 1006].

Under the Flexible Purchase Alternative, the long-term average flow in the Sacramento River below Keswick Dam during dry years would be essentially equivalent to or greater than the Baseline Condition for 180 months of the 192 months included in the analysis. The decreases would occur in 1 of the 16 years included in the analysis in July, in 4 of the 16 years included in the analysis in August, and in 7 of the 16 years included in the analysis in September. The long-term average flow decrease during dry years would average 17 cfs in July, 42 cfs in August, and 87 cfs in September, representing a 0.1 percent, 0.5 percent, 0.5 percent, and 1.7 percent decrease, respectively, compared to the Baseline Condition [Appendix H, p. 1006].

Under the Flexible Purchase Alternative, the long-term average flow in the Sacramento River below Keswick Dam during below normal years would be essentially equivalent to or greater than the Baseline Condition for 166 months of the 168 months included in the analysis. The decreases would occur in 1 of the 14 years included in the analysis in August and in 1 of the 14 years in September. The long-term average flow decrease during below normal years would average 445 cfs in August and 319 cfs in September, representing a 4.4 and 4.9 percent decrease for August and September, respectively, compared to the Baseline Condition [Appendix H, p. 1006].

The long-term average flow in the Sacramento River at Freeport would not decrease under the Flexible Purchase Alternative as compared to the Baseline Condition, during any month of the year as shown in Table G-26. In fact, long-term average flows in the Sacramento River at Freeport would increase by more than one percent from April through September under the Flexible Purchase Alternative as compared to the Baseline Condition. Long-term average flow at Freeport under the Flexible Purchase Alternative would increase by 1.9 percent in April, 1.8 percent in May, 1.9 percent in June, 17.7 percent in July, 15.7 percent in August, and 4.7 percent in September compared to the Baseline Condition. Furthermore, in 864 of 864 months simulated, Sacramento River flow at Freeport would be essentially equivalent to or greater than flow under the Baseline Condition [Appendix H, p. 385-396]. Therefore, under the Flexible Purchase Alternative, flow in the Sacramento River at Freeport during critical, dry, and below normal years would be essentially equivalent to or greater than the Baseline Condition for all months included in the analysis.

Table G-26
Long-term Average Sacramento River Flow at Freeport
Under the Baseline Condition and Flexible Purchase Alternative

Month	Monthly Mean Flow[1] (cfs)		Difference	
	Baseline Condition	Flexible Purchase Alternative	(cfs)	(%)[2]
Oct	11956	12044	88	0.7
Nov	14769	14783	14	0.1
Dec	24922	24927	5	0.0
Jan	33069	33071	2	0.0
Feb	39225	39226	1	0.0
Mar	34296	34299	3	0.0
Apr	25184	25665	481	1.9
May	19724	20076	352	1.8
Jun	18183	18533	350	1.9
Jul	17777	20919	3142	17.7
Aug	13762	15929	2167	15.7
Sep	13729	14373	644	4.7

[1] Based on 72 years modeled.
[2] Relative difference of the monthly long-term average.
Note: For a further description of the methodology used for the data assessment, please refer to Section 5.2.1 Assessment Methods.

Overall, under the Flexible Purchase Alternative, Sacramento River flow at Keswick Dam and Freeport would be essentially equivalent to or greater than the flows under the Baseline Condition. Increases in Sacramento River flow at Freeport during summer months would allow dilution of water quality constituents, including pesticides and fertilizers present in agricultural run-off. As a result, any differences in flow under the Flexible Purchase Alternative would not be expected to be of sufficient frequency and magnitude to affect water quality in a way that would result in long-term adverse effects to designated beneficial uses, exceedance of existing regulatory standards, or substantial degradation of water quality. Therefore, potential flow-related changes to water quality under the Flexible Purchase Alternative would be considered less than significant.

EWA acquisition of Sacramento River contractor water via stored reservoir water, groundwater substitution, and crop idling under the Flexible Purchase Alternative would not substantially increase Sacramento River water temperature, relative to the Baseline Condition.

Under the Flexible Purchase Alternative, long-term average water temperature in the Sacramento River at Bend Bridge would not differ during any month of the year, relative to the Baseline Condition (Table G-27). Moreover, under the Flexible Purchase Alternative, water temperatures in the Sacramento River at Bend Bridge would be essentially equivalent to or less than water temperatures under the Baseline Condition in 826 out of 828 months included in the analysis. Water temperature increases in 2 of 828 months modeled at Bend Bridge would range from 0.1 to 0.5°F [Appendix H, p. 469-480].

Table G-27 ***Long-term Average Water Temperature in the Sacramento River at Bend Bridge Under the Baseline Condition and Flexible Purchase Alternative***			
	Water Temperature[1] (ºF)		
Month	***Baseline Condition***	***Flexible Purchase Alternative***	***Difference (ºF)***
Oct	53.6	53.6	0.0
Nov	51.0	51.0	0.0
Dec	47.0	47.0	0.0
Jan	44.9	44.9	0.0
Feb	48.3	48.3	0.0
Mar	52.1	52.1	0.0
Apr	54.5	54.5	0.0
May	54.6	54.6	0.0
Jun	54.6	54.6	0.0
Jul	54.6	54.6	0.0
Aug	56.8	56.8	0.0
Sep	55.8	55.8	0.0

[1] Based on 69 years modeled.
Note: For a further description of the methodology used for the data assessment, please refer to Section 5.2.1 Assessment Methods.

Under the Flexible Purchase Alternative, the long-term average water temperature in the Sacramento River at Bend Bridge during critical years would be essentially equivalent to or less than the Baseline Condition for 132 months of the 132 months included in the analysis [Appendix H, p. 1008]. Under the Flexible Purchase Alternative, the long-term average water temperature in the Sacramento River at Bend Bridge during dry years would be essentially equivalent to or less than the Baseline Condition for 192 months of the 192 months included in the analysis [Appendix H, p. 1008].

Under the Flexible Purchase Alternative, the long-term average water temperature in the Sacramento River at Bend Bridge during below normal years would be essentially equivalent to or less than the Baseline Condition for 166 months of the 168 months included in the analysis. The increases would occur in 2 of the 14 years included in the analysis in September. The long-term average water temperature increase during below normal years would average 0.3°F in September, representing up to a 0.5 percent increase compared to the Baseline Condition [Appendix H, p. 1008].

Under the Flexible Purchase Alternative, long-term average water temperature in the Sacramento River at Freeport would not differ from long-term average water temperatures under the Baseline Condition by more than 0.1°F during any month, as shown in Table G-28. Additionally, water temperature in the Sacramento River at Freeport would be essentially equivalent to or less than water temperatures under the Baseline Condition in 828 out of 828 months included in the analysis [Appendix H, p. 481-492]. Therefore, under the Flexible Purchase Alternative, water temperature in the Sacramento River at Freeport during critical, dry, and below normal years would be essentially equivalent to or less than the Baseline Condition for all months included in the analysis.

Table G-28
Long-term Average Water Temperature in the Sacramento River at Freeport Under the Baseline Condition and Flexible Purchase Alternative

Month	Water Temperature[1] (ºF)		
	Baseline Condition	FPA	Difference (ºF)
Oct	60.1	60.1	0.0
Nov	52.5	52.5	0.0
Dec	46.0	45.9	-0.1
Jan	44.8	44.8	0.0

Apr	59.5	59.6	0.1
May	64.9	65.0	0.1
Jun	69.0	69.1	0.1
Jul	71.6	71.6	0.0
Aug	71.6	71.5	-0.1
Sep	68.4	68.3	-0.1

[1] Based on 69 years modeled.
Note: For a further description of the methodology used for the data assessment, please refer to Section 5.2.1 Assessment Methods.

Overall, water temperature in the Sacramento River at Bend Bridge and Freeport under the Flexible Purchase Alternative would be essentially equivalent to or less than water temperatures relative to the Baseline Condition. Any differences in water temperature would not be expected to be of sufficient frequency and magnitude to affect water quality in such as way that would result in long-term adverse effects to designated beneficial uses, exceedance of existing regulatory standards, or substantial degradation of water quality. Consequently, potential water temperature-related changes to water quality would be less than significant.

Lower Feather River

EWA acquisition of Feather River contractor water via stored reservoir water, groundwater substitution and crop idling under the Flexible Purchase Alternative would not substantially decrease Feather River flow, relative to the Baseline Condition.

The long-term average flow in the Feather River below the Thermalito Afterbay would not decrease under the Flexible Purchase Alternative as compared to the Baseline Condition, during any month of the year as shown in Table G-29. In fact, long-term average flows in the lower Feather River below the Thermalito Afterbay would increase by more than one percent from April through October under the Flexible Purchase Alternative as compared to the Baseline Condition. Long-term average flow below the Thermalito Afterbay under the Flexible Purchase Alternative would increase by 9.3 percent in April, 3.7 percent in May, 2.1 percent in June, 22.3 percent in July, 29.4 percent in August, 23.6 percent in September, and 2.8 percent in October (Table G-29), compared to the Baseline Condition. Furthermore, in 857 of 864 months simulated, Feather River flow below the Thermalito Afterbay would be essentially equivalent to or greater than flow under the Baseline Condition. The decrease in flow would occur in the month of July, when the long-term average flow would decrease by 3.9 percent [Appendix H, p. 892-903].

Table G-29
Long-term Average lower Feather River Flow Below Thermalito Afterbay Under the Baseline Condition and Flexible Purchase Alternative

Month	Monthly Mean Flow[1] (cfs)		Difference	
	Baseline Condition	FPA	(cfs)	(%)[2]
Oct	2441	2509	68	2.8
Nov	2301	2315	14	0.6
Dec	3984	3989	5	0.1
Jan	5005	5007	2	0.0

Note: For a further description of the methodology used for the data assessment, please refer to Section 5.2.1 Assessment Methods.

Under the Flexible Purchase Alternative, the long-term average flows in the Feather River below Thermalito Afterbay during critical years would be essentially equivalent to or greater than the Baseline Condition for 101 months of the 132 months included in the analysis. Within critical years, the long-term average flow in the Feather River below Thermalito Afterbay would decrease in 11 of the 11 years included in the analysis each in May and June, in 4 of the 11 years included in the analysis in February, and 1 of the 11 years included in the analysis in March and October through January. The long-term average flow decrease during critical years would average 1 cfs or less for all months, representing a 0.1 percent or less decrease, compared to the Baseline Condition [Appendix H, p. 1019].

Under the Flexible Purchase Alternative, the long-term average flow in the Feather River below Thermalito Afterbay during dry years would be essentially equivalent to or greater than the Baseline Condition for 128 months of the 192 months included in the analysis. Within dry years, the long-term average flow in the Feather River below Thermalito Afterbay would decrease in 16 of the 16 years included in the analysis in May and June, in 6 of the 16 years included in the analysis in February and April, in 4 of the 16 years included in the analysis in July, in 3 of the 16 years included in the analysis in January, March, and October through December, and in 1 of the 16 years included in the analysis in September. The long-term average flow decrease during dry years would average 163 cfs in July and 3 cfs or less for all other months, representing a 2 percent decrease in July and 0.2 percent or smaller decrease for all other months, compared to the Baseline Condition [Appendix H, p. 1019].

Under the Flexible Purchase Alternative, the long-term average flow in the Feather River below Thermalito Afterbay during below normal years would be essentially

equivalent to or greater than the Baseline Condition for 94 of the 168 months included in the analysis. Within below normal years, the long-term average flow in the Feather River below Thermalito Afterbay would decrease in 14 of the 14 years included in the analysis in June, in 13 of the 14 years included in the analysis in May, in 7 of the 14 years included in the analysis in April, in 6 of the 14 years included in the analysis in February and September, in 5 of the 14 years included in the analysis in March and October through January, and in 3 of the 14 years included in the analysis in July. The long-term average flow decrease for below normal years would average 252 cfs in July and 4 cfs or less for all other months, representing a 3 percent decrease in July and 0.1 percent or less for all other months, compared to the Baseline Condition [Appendix H, p. 1019].

The long-term average flow at the mouth of the Feather River would not decrease under the Flexible Purchase Alternative as compared to the Baseline Condition, during any month of the year, as shown in Table G-30. In fact, flows in the Feather River at the mouth would increase by more than one percent from April through October under the Flexible Purchase Alternative, compared to the Baseline Condition. Long-term average flow at the mouth of the Feather River under the Flexible Purchase Alternative would increase by 3.3 percent in April, 1.8 percent in May, 1.4 percent in June, 34.6 percent in July, 33.4 percent in August, 13.2 percent in September, and 2.1 percent in October, compared to the Baseline Condition. Furthermore, in 864 of 864 months simulated, Feather River flow at the mouth would be essentially equivalent to or greater than flow under the Baseline Condition [Appendix H, p. 868-879]. Therefore, under the Flexible Purchase Alternative, flow at the mouth of the Feather River during critical, dry, and below normal years would be essentially equivalent to or greater than the Baseline Condition for all months included in the analysis.

Table G-30
Long-term Average Feather River Flow at the Mouth
Under the Baseline Condition and Flexible Purchase Alternative

Month	Monthly Mean Flow[1] (cfs)		Difference	
	Baseline Condition	FPA	(cfs)	(%)[2]
Oct	3284	3352	68	2.1
Nov	3482	3496	14	0.4

[1] Based on 72 years modeled.
[2] Relative difference of the monthly long-term average.
Note: For a further description of the methodology used for the data assessment, please refer to Section 5.2.1 Assessment Methods.

Overall, under the Flexible Purchase Alternative, Feather River flow below the Thermalito Afterbay and at the mouth would be essentially equivalent to or greater than the flows under the Baseline Condition. Increases in Feather River flow below Thermalito Afterbay and at the mouth during summer months would allow dilution of water quality constituents, including pesticides and fertilizers present in agricultural run-off. As a result, any differences in flow would not be expected to be of sufficient frequency and magnitude to affect water quality in a way that would result in long-term adverse effects to designated beneficial uses, exceedance of existing regulatory standards, or substantial degradation of water quality. Therefore, potential flow-related changes to water quality under the Flexible Purchase Alternative would be less than significant.

EWA acquisition of Feather River contractor water via stored reservoir water, groundwater substitution, and crop idling under the Flexible Purchase Alternative would not substantially increase Feather River water temperature, relative to the Baseline Condition. Under the Flexible Purchase Alternative, long-term average water temperature in the Feather River at the Fish Barrier Dam would not differ during any month of the year, relative to the Baseline Condition (Table G-31). Moreover, under the Flexible Purchase Alternative, water temperatures in the Feather River at the Fish Barrier Dam would be essentially equivalent to water temperatures under the Baseline Condition in 828 out of 828 months included in the analysis [Appendix H, p. 940-951].

Table G-31
Long-term Average Water Temperature in the Feather River Below the Fish Barrier Dam Under the Baseline Condition and Flexible Purchase Alternative

Month	Water Temperature[1] (ºF)		
	Baseline Condition	FPA	Difference (ºF)
Oct	54.0	54.0	0.0
Nov	52.4	52.4	0.0
Dec	48.0	48.0	0.0
Jan	46.0	46.0	0.0
Feb	47.1	47.1	0.0
Mar	49.0	49.0	0.0
Apr	51.0	51.0	0.0
May	55.3	55.3	0.0

Jul	61.6	61.6	0.0
Aug	60.8	60.8	0.0
Sep	56.5	56.5	0.0

[1] Based on 69 years modeled.
Note: For a further description of the methodology used for the data assessment, please refer to Section 5.2.1 Assessment Methods.

Under the Flexible Purchase Alternative, long-term average water temperature in the Feather River below Thermalito Afterbay would not differ from long-term average temperatures under the Baseline Condition during any month of the year, as shown in Table G-32. Additionally, water temperature in the Feather River below the Thermalito Afterbay would be essentially equivalent to water temperatures under the Baseline Condition in 827 out of 828 months included in the analysis. The greatest decrease in temperature would be 0.1°F, occurring in July during a wet year

[Appendix H, p. 916-927]. Therefore, under the Flexible Purchase Alternative, water temperature below the Thermalito Afterbay in the Feather River during critical, dry, and below normal years would be essentially equivalent to or less than the Baseline Condition for all months included in the analysis.

Table G-32
Long-term Average Water Temperature in the Feather River Below Thermalito Afterbay Under the Baseline Condition and Flexible Purchase Alternative

Month	Water Temperature[1] (ºF)		
	No Action/No Project Alternative	FPA	Difference (ºF)
Oct	59.6	59.6	0.0
Nov	53.0	53.0	0.0
Dec	46.4	46.4	0.0
Jan	45.3	45.3	0.0

Sep	64.7	64.7	0.0

[1] Based on 69 years modeled.
Note: For a further description of the methodology used for the data assessment, please refer to Section 5.2.1 Assessment Methods.

Under the Flexible Purchase Alternative, long-term average water temperature at the mouth of the Feather River would not increase from the long-term average water temperature under the Baseline Condition by more than 0.2°F during any month, as shown in Table G-33. Additionally, water temperature at the mouth of the Feather River would be essentially equivalent to or less than water temperatures under the Baseline Condition in 796 out of 828 months included in the analysis. Water temperature increases in 32 of 828 months modeled would range from 0.4 to 0.7°F [Appendix H, p. 928-939].

Table G-33
Long-term Average Water Temperature at the Mouth of the Feather River Under the Baseline Condition and Flexible Purchase Alternative

Month	Water Temperature[1] (ºF)		
	Baseline Condition	FPA	Difference (ºF)
Oct	61.3	61.3	0.0
Nov	52.4	52.4	0.0
Dec	45.9	45.9	0.0
Jan	45.3	45.3	0.0
Feb	49.6	49.6	0.0
Mar	54.2	54.2	0.0
Apr	59.8	59.9	0.1
May	65.5	65.6	0.1
Jun	70.0	70.2	0.2

Aug	72.2	71.8	-0.4
Sep	69.7	69.2	-0.5

[1] Based on 69 years modeled.
Note: For a further description of the methodology used for the data assessment, please refer to Section 5.2.1 Assessment Methods.

Under the Flexible Purchase Alternative, the long-term average water temperature at the mouth of the Feather River during critical years would be essentially equivalent to or less than the Baseline Condition for 113 months of the 132 months included in the analysis. Within critical years, the long-term average water temperature in the Feather River at the mouth would not decrease in all months of the year except during July through September and May, and increases in the long-term average water temperature would occur in all months of the year except during November through March and August. The increases would occur in 1 of the 11 years included in the analysis in October and September, in 9 of the 11 years included in the analysis in April, in 8 of the 11 years included in the analysis in May, in 6 of the 11 years included in the analysis in June, and in 4 of the 11 years included in the analysis in July. The greatest long-term average water temperature increase during critical years would occur in May. During May, the long-term average water temperature would increase by 0.35ºF, representing up to a 0.5 percent increase compared to the Baseline Condition [Appendix H, p. 1018].

Under the Flexible Purchase Alternative, the long-term average water temperature in the Feather River at the mouth during dry years would be essentially equivalent to or less than the Baseline Condition for 164 months of the 192 months included in the analysis. Within dry years, the long-term average water temperature at the mouth of the Feather River would not decrease in any months of the year except July through September. Increases would occur in all months of the year except during November through March and September. The increases would occur in 4 of the 16 years included in the analysis in October, and would range from 3 to 10 of the 16 years included in the analysis during April through August. The greatest long-term average water temperature increase during dry years would occur during May. During May, the long-term average water temperature would increase by 0.33ºF, representing up to a 0.5 percent increase compared to the Baseline Condition [Appendix H, p. 1018].

Under the Flexible Purchase Alternative, the long-term average water temperature at the mouth of the Feather River during below normal years would be essentially equivalent to or less than the Baseline Condition for 141 months of the 168 months included in the analysis. During below normal years, the long-term average water temperature at the mouth of the Feather River would not decrease in any month of the year except during July through September, and increases would occur in all months of the year except during October through March and September. The increases would range from 2 to 7 years of the 14 years included in the analysis in April through August. The greatest long-term average water temperature increase during below normal years would occur during June. During June, the long-term average water temperature would increase by 0.24ºF, representing up to a 0.3 percent increase compared to the Baseline Condition [Appendix H, p. 1018].

Overall, water temperature in the Feather River below the Thermalito Afterbay, and at the mouth under the Flexible Purchase Alternative would infrequently be increased

by up to 0.7°F and would otherwise be essentially equivalent to or less than water temperatures relative to the Baseline Condition. Any differences in water temperature would not be expected to be of sufficient frequency and magnitude to affect water quality in a way that would result in long-term adverse effects to designated beneficial uses, exceedance of existing regulatory standards, or substantial degradation of water quality. Consequently, potential water temperature-related changes to water quality would be less than significant.

Lower Yuba River

EWA acquisition of lower Yuba River contractor water via stored reservoir water, groundwater substitution and crop idling under the Flexible Purchase Alternative would alter lower Yuba River flow, relative to the Baseline Condition.

The Yuba River is one of many Central Valley rivers that have been utilized in water transfer projects for a number of years. In 2001, Yuba County Water Agency (YCWA) and other local water agencies initiated water transfers from New Bullards Bar Reservoir through the Yuba River in order to satisfy a variety of downstream needs. The total water transfer consisted of approximately 172,000 acre-feet of water, including 114,052 acre-feet utilized by DWR. The water transfers occurred approximately between July 1, 2001 and October 14, 2001. The water transfers increased flows by about 1,200 cfs in the lower Yuba River through late August. Yuba River water transfers also occurred during 2002. Yuba County Water Agency transferred a total of 162,050 acre-feet of water for downstream needs (157,050 acre-feet allocated to DWR, and 5,000 acre-feet to the Contra Costa Water District) from approximately mid-June through September, 2002.

Recent historic flows in the Yuba River below Englebright Dam during June through October, the typical time period for water transfers, have been between approximately 600 and 2,500 cfs. Preliminary hydrologic modeling output for flows under the Baseline Condition (without EWA transfer) below Englebright Reservoir would range between approximately 1,000 and 1,800 cfs during June, July, and most of August, ramp down in late August and early September to 500 cfs to 900 cfs, and remain relatively constant at 600 to 900 cfs for October and November until the wet season, at which time unregulated winter storm and snowmelt flows affect the lower Yuba River hydrology. Below Daguerre Point Dam, baseline flows could range from approximately 245 to 800 cfs in June, and from 100 to 250 cfs during July, August, and September. Flows below Daguerre Point Dam in the first two weeks in October could be about 320 to 400 cfs and increase to 400 to 500 cfs for the last two weeks of October through the time period in the winter when runoff from winter storms significantly affect river flows.

Under the maximum transfer scenario of the Flexible Purchase Alternative, the proposed transfer of 185,000 acre-feet to the EWA is expected to take place mainly in July and August, with some water potentially released between June 1 and July 31, and between September 1 and October 31. During late June, July, and August, flow rates would be relatively constant, at up to 1,200 to 1,500 cfs above Yuba River

instream flow and diversion delivery requirements. Under the variable transfer scenario of the Flexible Purchase Alternative, the expected amount of water to be transferred to the EWA is 30,000 acre-feet. As with the maximum transfer, the delivery of this water would take place mainly in July and August, with some water released between September 1 and October 31. Releases of transfer water would start in June or early July and would depend on Delta conditions and the SWP's ability to pump the water. During late June, July, and August, flow rates would be relatively constant, at up to 500 cfs above Yuba River instream flow and diversion delivery requirements. This maximum flow rate would occur if all of the transfer water were to be delivered in one month. Transfers under either scenario could affect water levels in Lake Oroville only if DWR released stored water to compensate for reduced flows to the Delta during the period when New Bullards Bar Reservoir was being refilled by the additional amount of evacuated storage resulting from the transfer. The need for increased releases from Lake Oroville resulting from reduced releases from New Bullards Bar Reservoir and thus reduced Yuba River outflow would occur only under certain hydrologic conditions.

Overall, under the Flexible Purchase Alternative, lower Yuba River flow would be greater than the flows under the Baseline Condition, based on data from previous water transfers. Increases in lower Yuba River flow would allow dilution of water quality constituents, including pesticides and fertilizers present in agricultural run-off. As a result, increases in flow would not be expected to be of sufficient frequency and magnitude to affect water quality in such as way that would result in long-term adverse effects to designated beneficial uses, exceedance of existing regulatory standards, or substantial degradation of water quality. Therefore, potential flow-related changes to water quality under the Flexible Purchase Alternative would be less than significant.

EWA acquisition of lower Yuba River contractor water via stored reservoir water, groundwater substitution and crop idling under the Flexible Purchase Alternative would alter lower Yuba River water temperature, relative to the Baseline Condition.

Monitoring of lower Yuba River water temperatures during past water transfers showed that water temperatures at the mouth of the Yuba River (Highway 70 Bridge) were approximately 73°F prior to the 2001 water transfers. At the same time, similar water temperatures were observed on the Feather River, one kilometer above its confluence with the Yuba River. After the initiation of the 2001 water transfers, water temperatures at the mouth of the Yuba River dropped to an average of 61°F for the remainder of the month (CDFG, unpublished data). Water temperatures at this site remained around 61°F until flows were reduced in late August, at which time the water temperatures increased coincident with flow reduction. Although an evaluation of the numerous variables (e.g., ambient air temperature, cloud cover, diversion rates) which may influence instream water temperatures has not yet been conducted, changes in Yuba River water temperatures were observed coincident with the water transfers.

Overall, under the Flexible Purchase Alternative, lower Yuba River water temperatures would be less than the water temperatures under the Baseline Condition, based on data from previous water transfers. Decreases in Yuba River water temperature with implementation of the Flexible Purchase Alternative would not be of sufficient frequency and magnitude to affect water quality in such as way that would result in long-term adverse effects to designated beneficial uses, exceedance of existing regulatory standards, or substantial degradation of water quality. Consequently, potential water temperature-related changes to water quality would be less than significant.

Middle Fork American River

EWA acquisition of American River contractor water via stored reservoir water and crop idling under the Flexible Purchase Alternative would alter Middle Fork American River flow, relative to the Baseline Condition.

The median flow in the Middle Fork American River below Ralston Afterbay would not decrease under the Flexible Purchase Alternative, compared to the Baseline Condition, during nine months of the year as shown in Table G-16. In fact, the median flow in the Middle Fork American River below Ralston Afterbay under the Flexible Purchase Alternative would increase in comparison to flows under the Baseline Condition in June through September. Flows would increase 10.7 percent in June, 17.1 percent in July, 16.1 percent in August, and 9.6 percent in September. However, median flow in the Middle Fork American River would decrease under the Flexible Purchase Alternative, compared to the Baseline Condition, during November, January and February. Median flow in the Middle Fork American River would decrease by 43.6 percent in November, 5.3 percent in January, and 25.6 percent in February.

The median flow in the Middle Fork American River below Ralston Afterbay during critical, dry, and below normal years under the Flexible Purchase Alternative, compared to the Baseline Condition are shown in Table G-17 and Table G-18. The median flow in the Middle Fork American River below Ralston Afterbay under the Flexible Purchase Alternative during critical years would increase in comparison to flows under the Baseline Condition in June through September. Flows during critical years would increase 20.5 percent in June, 23.5 percent in July, 27.5 percent in August, and 13.3 percent in September. However, median flow in the Middle Fork American River during critical years would decrease under the Flexible Purchase Alternative, compared to the Baseline Condition, during October and November. Median flow in the Middle Fork American River during critical years would decrease by 81.9 percent in October and 19.2 percent in November.

The median flow in the Middle Fork American River below Ralston Afterbay under the Flexible Purchase Alternative during dry and below normal years would increase in comparison to flows under the Baseline Condition in June through September. Flows during dry and below normal years would increase 16.5 percent in June, 21.3 percent in July, 18.1 percent in August, and 10.0 percent in September. However,

median flow in the Middle Fork American River during dry and below normal years would decrease under the Flexible Purchase Alternative, compared to the Baseline Condition, during November. Median flow in the Middle Fork American River during dry and below normal years would decrease by 60 percent in November.

Overall, under the Flexible Purchase Alternative, Middle Fork American River median flow below Ralston Afterbay would be essentially equivalent to greater than flows under the Baseline Condition in nine months out of the year. Median flow in the Middle Fork American River would decrease in November, January, and February under the Flexible Purchase Alternative as compared to the Baseline Condition. Increases in Middle Fork American River flow below Ralston Afterbay in June, July, August, and September would allow dilution of water quality constituents. Decreased flows during the months of greatest flow reduction (November and February) would not be expected to cause an increase in water quality constituents that would result in adverse effects to designated beneficial uses, exceedance of existing regulatory standards, or substantial degradation of water quality because the water quality in the Middle Fork American River is of high quality and concentrations of constituents are generally low. Consequently, potential flow-related effects to water quality would be considered less than significant.

Lower American River

EWA acquisition of stored groundwater from Sacramento Groundwater Authority members, stored reservoir water, and water obtained through Placer Country Water Agency crop idling and retained in Folsom Reservoir under the Flexible Purchase Alternative would increase lower American River flow, relative to the Baseline Condition.

The long-term average flow in the lower American River below Nimbus Dam would not decrease under the Flexible Purchase Alternative, compared to the Baseline Condition, during all months of the year as shown in Table G-34. In fact, long-term average lower American River flow below Nimbus Dam under the Flexible Purchase Alternative would increase by 2.6 percent in July, 1.9 percent in August, and 2.6 percent in September, compared to the Baseline Condition. Further, in 864 out of 864 months simulated, lower American River flow below Nimbus Dam under the Flexible Purchase Alternative would be essentially equivalent to or greater than flow under the Baseline Condition [Appendix H, p. 313-324]. Therefore, under the Flexible Purchase Alternative, flow in the lower American River below Nimbus Dam during critical, dry, and below normal years would be essentially equivalent to or greater than the Baseline Condition for all months included in the analysis [Appendix H, p. 1015].

Table G-34
Long-term Average Release to the Lower American River From Nimbus Dam Under the Baseline Condition and Flexible Purchase Alternative

Month	Monthly Mean Flow[1] (cfs)		Difference	
	Baseline Condition	Flexible Purchase Alternative	(cfs)	(%)[2]

Sep	2876	2885	9	2.6

[1] Based on 72 years modeled.
[2] Relative difference of the monthly long-term average.
Note: For a further description of the methodology used for the data assessment, please refer to Section 5.2.1 Assessment Methods.

The long-term average lower American River flow at Watt Avenue would not decrease under the Flexible Purchase Alternative as compared to the Baseline Condition, during any month of the year as shown in Table G-35. In fact, long-term average flow at Watt Avenue under the Flexible Purchase Alternative would increase by 2.9 percent in July and 2.1 percent in August, compared to the Baseline Condition. Furthermore, in 864 of 864 months simulated, lower American River flow at Watt Avenue would be essentially equivalent to or greater than flow under the Baseline Condition [Appendix H, p. 325-336]. Therefore, under the Flexible Purchase Alternative, flow at Watt Avenue in the lower American River during critical, dry, and below normal years would be essentially equivalent to or greater than the Baseline Condition for all months included in the analysis.

The long-term average flow at the mouth of the American River would not decrease under the Flexible Purchase Alternative as compared to the Baseline Condition, during any month of the year as shown in Table G-36. In fact, long-term average flow at the mouth of the American River under the Flexible Purchase Alternative would increase by 2.8 percent in July and 2.0 percent in August, compared to the Baseline Condition. Furthermore, in 864 of 864 months simulated, American River flow at the mouth would be essentially equivalent to or greater than flow under the Baseline Condition [Appendix H, p. 361-372]. Therefore, under the Flexible Purchase Alternative, flow at the mouth of the American River during critical, dry, and below normal years would be essentially equivalent to or greater than the Baseline Condition for all months included in the analysis.

[1] Based on 72 years modeled.
[2] Relative difference of the monthly long-term average.
Note: For a further description of the methodology used for the data assessment, please refer to Section 5.2.1, Assessment Methods.

Overall, under the Flexible Purchase Alternative, lower American River flow below Nimbus Dam, at Watt Avenue, and at the mouth would be essentially equivalent to or greater than the flows under the Baseline Condition. Increases in lower American River flow at all three locations during July and August and during September at Nimbus Dam would allow dilution of water quality constituents, including pesticides and fertilizers present in agricultural run-off. As a result, any differences in flow would not be expected to be of sufficient frequency and magnitude to affect water quality in a way that would result in long-term adverse effects to designated beneficial uses, exceedance of existing regulatory standards, or substantial

degradation of water quality. Therefore, potential flow-related changes to water quality under the Flexible Purchase Alternative would be considered less than significant.

EWA acquisition of stored groundwater from Sacramento Groundwater Authority members, stored reservoir water, and water obtained through Placer Country Water Agency crop idling and retained in Folsom Reservoir under the Flexible Purchase Alternative would not substantially increase American River water temperature, relative to the Baseline Condition. Under the Flexible Purchase Alternative, long-term average water temperature in the American River below Nimbus Dam would not differ by more than 0.2ºF during any month of the year, relative to the Baseline Condition (Table G-37). Moreover, under the Flexible Purchase Alternative, water temperatures in the American River below Nimbus Dam would be essentially equivalent to or less than water temperatures under the Baseline Condition in 805 out of 828 months included in the analysis. Water temperature increases in 23 of 828 months modeled below Nimbus Dam would range from 0.4 to 1.0°F [Appendix H, p. 409-420].

Table G-37
Long-term Average Water Temperature in the American River Below Nimbus Dam Under the Baseline Condition and Flexible Purchase Alternative

Month	Water Temperature[1] (ºF)		
	Baseline Condition	Flexible Purchase Alternative	Difference (ºF)

[1] Based on 69 years modeled.
Note: For a further description of the methodology used for the data assessment, please refer to Section 5.2.1, Assessment Methods.

Under the Flexible Purchase Alternative, the long-term average water temperature in the American River below Nimbus Dam during critical years would be essentially equivalent to or less than the Baseline Condition for 121 months of the 132 months included in the analysis. Within critical years, the long-term average water temperature in the American River below Nimbus Dam would not decreases in any months of the year except during November through January, April and September, and increases in the long-term average water temperature would occur all months of the year except during December and January. The increases would occur in 6 of the 11 years included in the analysis in October, in 3 of the 11 years included in the analysis in February, in 7 of the 11 years included in the analysis in November, March, June, and September, in 5 of the 11 years included in the analysis in April and August, in 4 of the 11 years included in the analysis in May, and in 1 of the 11 years

included in the analysis in July. The greatest long-term average water temperature increase during critical years would occur during September. During September, the long-term average water temperature would increase by 0.36°F, representing up to a 0.5 percent increase compared to the Baseline Condition [Appendix H, p. 1016].

Under the Flexible Purchase Alternative, the long-term average water temperature in the American River below Nimbus Dam during dry years would be essentially equivalent to or less than the Baseline Condition for 161 months of the 192 months included in the analysis. Within dry years, the long-term average water temperature in the American River below Nimbus Dam would decrease during all months of the year except during March through April and July through September. Increases would occur during all months of the year except during December and January. The increases would occur in 5 of the 16 years included in the analysis in October, in 3 of the 16 years included in the analysis in November, and would range from 2 to 13 of the 16 years included in the analysis in February through September. The greatest long-term average water temperature increase during dry years would occur during September. During September, the long-term average water temperature would increase by 0.27°F, representing up to a 0.5 percent increase compared to the Baseline Condition [Appendix H, p. 1016].

Under the Flexible Purchase Alternative, the long-term average water temperature in the American River below Nimbus Dam during below normal years would be essentially equivalent to or less than the Baseline Condition for 144 months of the 168 months included in the analysis. During below normal years, the long-term average water temperature in the American River below Nimbus Dam would decrease in all months of the year except during March through April, and increases would occur all months of the year except during December through January. The increases would range from 5 to 6 years of the 14 years included in the analysis in October through November and would range from 2 to 13 of the 14 years included in the analysis in February through September. The greatest long-term average temperature increase during below normal years would occur during October. During October, the long-term average water temperature would increase by 0.25°F, representing up to a 0.4 percent increase compared to the Baseline Condition [Appendix H, p. 1016].

Under the Flexible Purchase Alternative, long-term average water temperature in the American River at Watt Avenue would not differ from long-term average water temperatures under the Baseline Condition by more than 0.1°F during any month, as shown in Table G-38. Additionally, water temperature in the American River at Watt Avenue would be essentially equivalent to or less than water temperatures under the Baseline Condition in 815 out of 828 months included in the analysis. Water temperature increases in 13 of 828 months modeled would range from 0.4 to 0.7°F [Appendix H, p. 421-432].

Under the Flexible Purchase Alternative, the long-term average water temperature in the American River at Watt Avenue during critical years would be essentially equivalent to or less than the Baseline Condition for 124 months of the 132 months

included in the analysis. Within critical years, the long-term average water temperature in the American River at Watt Avenue would not decrease in any months of the year except during November through January, and increases in the long-term average water temperature would occur all months of the year except during December through January. The increases would occur in 4 of the 11 years included in the analysis in October, April, and September, in 2 of the 11 years included in the analysis in February, in 5 of the 11 years included in the analysis in March, in 6 of the 11 years included in the analysis in November and June, in 3 of the 11 years included in the analysis in May and August, and in 1 of the 11 years included in the analysis in July. The greatest long-term average water temperature increase during critical years would occur during September. During September, the long-term average water temperature would increase by 0.33ºF, representing up to a 0.5 percent increase compared to the Baseline Condition [Appendix H, p. 1014].

Table G-38
Long-term Average Water Temperature in the American River at Watt Avenue Under the Baseline Condition and Flexible Purchase Alternative

Month	Water Temperature[1] (ºF)		
	Baseline Condition	Flexible Purchase Alternative	Difference (ºF)
Oct	57.7	57.7	0.0
Nov	55.8	55.8	0.0

Aug	66.9	66.9	0.0
Sep	66.8	66.8	0.0

[1] Based on 69 years modeled.
Note: For a further description of the methodology used for the data assessment, please refer to Section 5.2.1 Assessment Methods.

Under the Flexible Purchase Alternative, the long-term average water temperature in the American River at Watt Avenue during dry years would be essentially equivalent to or less than the Baseline Condition for 167 months of the 192 months included in the analysis. Within dry years, the long-term average water temperature in the American River at Watt Avenue would not decrease in any months of the year except during October through February. Increases would occur all months of the year except during December through January. The increases would occur in 5 of the 16 years included in the analysis in October, in 3 of the 16 years included in the analysis in November, and would range from 2 to 12 of the 16 years included in the analysis during February through September. The greatest long-term average water temperature increase during dry years would occur during July, August, and September. During these months the long-term average water temperature would increase by 0.20ºF, representing up to a 0.3 percent increase compared to the Baseline Condition [Appendix H, p. 1014].

Under the Flexible Purchase Alternative, the long-term average water temperature in the American River at Watt Avenue during below normal years would be essentially equivalent to or less than the Baseline Condition for 147 months of the 168 months included in the analysis. During below normal years, the long-term average water temperature in the American River at Watt Avenue would decrease in all months of the year except during March through May, and increases would occur in all months of the year except during December and January. The increases would occur in 5 of the 14 years included in the analysis in October, 3 of the 14 years included in the analysis in November, and would range from 2 to 8 of the 14 years included in the analysis during February through September. The greatest long-term average water temperature increase during below normal years would occur during November. During November, the long-term average water temperature would increase by 0.23°F, representing up to a 0.4 percent increase compared to the Baseline Condition [Appendix H, p. 1014].

Under the Flexible Purchase Alternative, long-term average water temperature at the mouth of the American River would not differ from long-term average temperatures under the Baseline Condition by more than 0.1°F during any month, as shown in Table G-39. Additionally, water temperature in the American River at the mouth would be essentially equivalent to or less than water temperatures under the Baseline Condition in 821 out of 828 months included in the analysis. Water temperature increases in 9 of 828 months modeled would range from 0.4 to 0.6°F [Appendix H, p. 433-444].

Table G-39
Long-term Average Water Temperature at the Mouth of the American River Under the Baseline Condition and Flexible Purchase Alternative

Month	Water Temperature[1] (°F)		
	Baseline Condition	Flexible Purchase Alternative	Difference (°F)
Oct	58.4	58.4	0.0
Nov	55.5	55.5	0.0
Dec	49.7	49.6	-0.1
Jan	46.5	46.5	0.0
Feb	48.5	48.5	0.0
Mar	51.7	51.8	0.1
Apr	55.8	55.9	0.1
May	59.7	59.8	0.1
Jun	63.2	63.3	0.1
Jul	67.2	67.2	0.0
Aug	68.1	68.1	0.0
Sep	67.3	67.3	0.0

[1] Based on 69 years modeled.
Note: For a further description of the methodology used for the data assessment, please refer to Section 5.2.1 Assessment Methods.

Under the Flexible Purchase Alternative, the long-term average water temperature at the mouth of the American River during critical years would be essentially equivalent to or less than the Baseline Condition for 115 months of the 132 months included in the analysis. Within critical years, the long-term average water temperature in the

American River at the mouth would decrease in all months of the year except during March through June and October. Increases in the long-term average water temperature would occur all months of the year except during December and January. The increases would range from 3 to 4 of the 11 years included in the analysis in October through November and would range from 2 to 7 of the 11 years included in the analysis in February through September. The greatest long-term average water temperature increase during critical years would occur during September. During September, the long-term average water temperature would increase by 0.45°F, representing up to a 0.7 percent increase compared to the Baseline Condition [Appendix H, p. 1012].

Under the Flexible Purchase Alternative, the long-term average water temperature at the mouth of the American River during dry years would be essentially equivalent to or less than the Baseline Condition for 159 months of the 192 months included in the analysis. Within dry years, the long-term average water temperature in the American River at the mouth would decrease in all months of the year except during March and April. Increases would occur in all months of the year except during December and January. The increases would occur in 4 of the 16 years included in the analysis in October, August, and September, in 3 of the 16 years included in the analysis in November and July, and would range from 1 to 13 of the 16 years included in the analysis during February through June. The greatest long-term average water temperature increase during dry years would occur during July. During July, the long-term average water temperature would increase by 0.20°F, representing up to a 0.3 percent increase compared to the Baseline Condition [Appendix H, p. 1012].

Under the Flexible Purchase Alternative, the long-term average water temperature at the mouth of the American River during below normal years would be essentially equivalent to or less than the Baseline Condition for 147 months of the 168 months included in the analysis. During below normal years, the long-term average water temperature at the mouth of the American River would decrease in all months of the year except during March through June, and increases would occur in all months of the year except during December, January, and July. The increases would occur in 5 of the 14 years included in the analysis in October and June, in 2 of the 14 years included in the analysis in November and September, in 1 of the 14 years included in the analysis in August, and would range from 3 to 10 of the 14 years included in the analysis in February through May. The greatest long-term average water temperature increase during below normal years would occur during November. During November, the long-term average water temperature would increase by 0.25°F, representing up to a 0.5 percent increase compared to the Baseline Condition [Appendix H, p. 1012].

Overall, water temperature in the American River below Nimbus Dam, at Watt Avenue and at the mouth under the Flexible Purchase Alternative would infrequently be increased by up to 1.0°F and would otherwise be essentially equivalent to or less than water temperatures relative to the Baseline Condition. Any differences in water temperature would not be of sufficient frequency and magnitude to affect water

quality in such as way that would result in long-term adverse effects to designated beneficial uses, exceedance of existing regulatory standards, or substantial degradation of water quality. Consequently, potential water temperature-related changes to water quality would be less than significant.

Merced River

EWA acquisition of Merced River contractor water via groundwater substitution under the Flexible Purchase Alternative would increase Merced River flow, relative to the Baseline Condition.

The long-term average flow in the Merced River below Crocker-Huffman Dam would not decrease under the Flexible Purchase Alternative, compared to the Baseline Condition, during any month of the year as shown in Table G-40. In fact, long-term average Merced River flow below Crocker Huffman Dam under the Flexible Purchase Alternative would increase in comparison to the Baseline Condition in October and November, when the long-term average flow would increase 25.0 percent and 90.9 percent, respectively. Further, in 864 out of 864 months simulated, Merced River flow below Crocker-Huffman Dam under the Flexible Purchase Alternative would be essentially equivalent to or greater than flow under the Baseline Condition [Appendix H, p. 964-975].

Table G-40
Long-term Average Flow Below Crocker-Huffman Dam
Under the Baseline Condition and Flexible Purchase Alternative

	Monthly Mean Flow[1] (cfs)		***Difference***	
Month	***Baseline Condition***	***Flexible Purchase Alternative***	***(cfs)***	***(%)[2]***
Oct	812	1015	203	25.0

[1] Based on 72 years modeled.
[2] Relative difference of the monthly long-term average.
Note: For a further description of the methodology used for the data assessment, please refer to Section 5.2.1 Assessment Methods.

The long-term average flow at the mouth of the Merced River would not decrease under the Flexible Purchase Alternative as compared to the Baseline Condition, during any month of the year as shown in Table G-41. In fact, flows in the Merced River at the mouth would increase in October and November under the Flexible Purchase Alternative as compared to the Baseline Condition. Long-term average flow at the mouth of the Merced River under the Flexible Purchase Alternative would

increase by 23.2 percent in October and 73.3 percent in November compared to the Baseline Condition. Furthermore, in 864 of 864 months simulated, Merced River flow at the mouth would be essentially equivalent to or greater than flow under the Baseline Condition [Appendix H, p. 976-987].

Table G-41
Long-term Average Flow at the Mouth of the Merced River
Under the Baseline Condition and Flexible Purchase Alternative

Month	Monthly Mean Flow[1] (cfs)		Difference	
	Baseline Condition	Flexible Purchase Alternative	(cfs)	(%)[2]
Oct	881	1085	204	23.2
Nov	288	499	211	73.3
Dec	438	438	0	0.0
Jan	596	596	0	0.0
Feb	936	936	0	0.0
Mar	654	654	0	0.0
Apr	517	517	0	0.0
May	865	865	0	0.0
Jun	827	827	0	0.0
Jul	333	333	0	0.0
Aug	189	189	0	0.0
Sep	193	193	0	0.0

[1] Based on 72 years modeled.
[2] Relative difference of the monthly long-term average.
Note: For a further description of the methodology used for the data assessment, please refer to Section 5.2.1 Assessment Methods.

Overall, under the Flexible Purchase Alternative, Merced River flow below Crocker-Huffman Dam and at the mouth would be essentially equivalent to or greater than the flows under the Baseline Condition. Increases in Merced River flow at Crocker-Huffman Dam and at the mouth during October and November would allow dilution of water quality constituents. As a result, any differences in flow would not be expected to be of sufficient frequency and magnitude to affect water quality in such a way that would result in long-term adverse effects to designated beneficial uses, exceedance of existing regulatory standards, or substantial degradation of water quality. Therefore, potential flow-related changes to water quality under the Flexible Purchase Alternative would be less than significant.

San Joaquin River

EWA acquisition of Merced River contractor water via groundwater substitution under the Flexible Purchase Alternative would increase San Joaquin River flow, relative to the Baseline Condition.

The long-term average flow in the San Joaquin River below the confluence with the Merced River would not decrease under the Flexible Purchase Alternative, compared to the Baseline Condition, during any month of the year as shown in Table G-42. In fact, long-term average San Joaquin River flow below the confluence with the Merced River under the Flexible Purchase Alternative would increase in comparison to flows under the Baseline Condition in October and November, when the long-term average flow would increase by 14.6 percent and 28.8 percent, respectively. Further, in 864

out of 864 months simulated, San Joaquin River flow below the confluence with the Merced River under the Flexible Purchase Alternative would be essentially equivalent to or greater than flow under the Baseline Condition [Appendix H, p. 988-999].

Table G-42
Long-term Average San Joaquin River Flow Below the Merced River Under the Baseline Condition and Flexible Purchase Alternative

Month	Monthly Mean Flow[1] (cfs)		Difference	
	Baseline Condition	Flexible Purchase Alternative	(cfs)	(%)[2]
Oct	1391	1594	203	14.6
Nov	729	939	210	28.8
Dec	1138	1138	0	0.0
Jan	1648	1648	0	0.0

May	2236	2236	0	0.0
Jun	1997	1997	0	0.0
Jul	830	830	0	0.0
Aug	575	575	0	0.0
Sep	774	774	0	0.0

[1] Based on 72 years modeled.
[2] Relative difference of the monthly long-term average.
Note: For a further description of the methodology used for the data assessment, please refer to Section 5.2.1 Assessment Methods.

The long-term average flow at Vernalis in the San Joaquin River (for this analysis, also referred to as the long-term average Delta inflow from the San Joaquin River) would not decrease under the Flexible Purchase Alternative as compared to the Baseline Condition, during any month of the year as shown in Table G-43. In fact, long-term average flows in the San Joaquin River at Vernalis under the Flexible Purchase Alternative would increase by 6.7 percent in October and 10.6 percent in November compared to the Baseline Condition. Furthermore, in 864 of 864 months simulated, San Joaquin River flow at Vernalis would be essentially equivalent to or greater than flow under the Baseline Condition [Appendix H, p. 73-84].

Overall, under the Flexible Purchase Alternative, San Joaquin River flow below the confluence with the Merced River and at Vernalis would be essentially equivalent to or greater than the flows under the Baseline Condition. Increases in San Joaquin River flow at both locations during October and November would allow dilution of water quality constituents, including pesticides and fertilizers present in agricultural run-off. As a result, any differences in flow would not be expected to be of sufficient frequency and magnitude to affect water quality in such as way that would result in long-term adverse effects to designated beneficial uses, exceedance of existing regulatory standards, or substantial degradation of water quality. Therefore, potential flow-related changes to water quality under the Flexible Purchase Alternative would be less than significant.

Appendix H: Technical Output for GATAER Process

July 2003

Technical Appendix Index			
Output Title/Definition	**Tab Number**	**Start Page**	**End Page**
Maximum Water Purchase -- Delta Outflow	A1	A1	A12
Maximum Water Purchase -- Delta X2 Position	A2	A13	A24
Maximum Water Purchase -- Total Delta Export (Banks + Tracy)	A3	A25	A36
Maximum Water Purchase -- Delta Q--West Flow	A4	A37	A48
Maximum Water Purchase -- Delta EI Ratio	A5	A49	A60
Typical Water Purchase -- Delta Outflow	B1	B1	B12
Typical Water Purchase -- Delta X2 Position	B2	B13	B24
Typical Water Purchase -- Total Delta Export (Banks + Tracy)	B3	B25	B36
Typical Water Purchase -- Delta Q--West Flow	B4	B37	B48
Typical Water Purchase -- Delta EI Ratio	B5	B49	B60
Delta Inflow, Sacramento River	6	61	72
Delta Inflow, San Joaquin River	7	73	84
Trinity Reservoir End of Month Storage	8	85	96
Shasta Reservoir End of Month Storage	9	97	108
Folsom Reservoir End of Month Storage	10	109	120
Oroville Reservoir End of Month Storage	11	121	132
Whiskeytown Reservoir End of Month Storage	12	133	144
French Meadows Reservoir End of Month Storage	13	145	156
Hell Hole Reservoir End of Month Storage	14	157	168
Trinity Reservoir End of Month Elevation	15	169	180
Shasta Reservoir End of Month Elevation	16	181	192
Folsom Reservoir End of Month Elevation	17	193	204
Oroville Reservoir End of Month Elevation	18	580	591
French Meadows Reservoir End of Month Elevation	19	205	216
Hell Hole Reservoir End of Month Elevation	20	217	228
Folsom Reservoir End of Month Surface Area	21	229	240
Trinity Reservoir End of Month Surface Area	22	241	252
Shasta Reservoir End of Month Surface Area	23	253	264
Trinity Reservoir Littoral Habitat	24	265	276
Shasta Reservoir Littoral Habitat	25	277	288
Folsom Reservoir Littoral Habitat	26	289	300
Flow Below Auburn Dam Diversion Site on the Upper American River	27	301	312
Release from Nimbus Dam on the Lower American River	28	313	324
Feather River Flow	29	592	603
Lower American River Flow at Watt Avenue	30	325	336
Lower American River Flow at the H St. Bridge	31	337	348
Release from Keswick Dam on the Sacramento River	32	349	360
Lower American River Flow at the Mouth	33	361	372
Flow Above Auburn Dam Diversion Site on the Upper American River	34	373	384
Sacramento River Flow at Freeport	35	385	396
Trintiy River Flow below the Clear Creek Tunnel	36	397	408
Feather River Temperature	37	604	615
Lower American River Temperature at Nimbus Dam	38	409	420
Lower American River Temperature at Watt Avenue	39	421	432
Lower American River Temperature at the Mouth	40	433	444
Sacramento River Temperature at Keswick Dam	41	445	456
Sacramento River Temperature at Jellys Ferry	42	457	468
Sacramento River Temperature at Bend Bridge	43	469	480
