Environmental Water Account EIS/EIR Table of Contents, Acronyms, and Abbreviations

Volume II

Chapter 10 Vegetation and Wildlife 10-1

10.1 Affected Environment/Existing Condition 10-1
- 10.1.1 Area of Analysis 10-2
- 10.1.2 Upstream from the Delta 10-5
- 10.1.3 Delta Region 10-30
- 10.1.4 Export Service Area 10-37

10.2 Environmental Consequences/Environmental Impacts 10-41
- 10.2.1 NCCP Communities and Special-Status Species Addressed in the EIS/EIR and ASIP 10-42
- 10.2.2 Assessment Methods 10-48
- 10.2.3 Significance Criteria 10-53
- 10.2.4 Environmental Measures Incorporated into the Program 10-53
- 10.2.5 Environmental Consequences/Environmental Impacts of the No Action/No Project Alternative 10-57
- 10.2.6 Environmental Consequences/Environmental Impacts of the Flexible Purchase Alternative 10-58
- 10.2.7 Environmental Consequences/Environmental Impacts of the Fixed Purchase Alternative 10-90
- 10.2.8 Comparative Analysis of the Alternatives 10-104
- 10.2.9 Mitigation Measures 10-111
- 10.2.10 Potentially Significant Unavoidable Impacts 10-111
- 10.2.11 Cumulative Effects 10-111

10.3 References 10-113

Chapter 11 Regional and Agricultural Economics 11-1

11.1 Affected Environment/Existing Conditions 11-1
- 11.1.1 Area of Analysis 11-1
- 11.1.2 Upstream from the Delta Region 11-2
- 11.1.3 Export Service Area 11-13
- 11.1.4 Property Tax Revenue 11-21
- 11.1.5 Groundwater Pumping Costs 11-22
- 11.1.6 Water Transfer Market Effects 11-22

11.2 Environmental Consequences/Environmental Impacts 11-24

11.2.1 NEPA/CEQA Issues 11-24
11.2.2 Assessment Methods 11-24
11.2.3 Environmental Measures Incorporated into the Project 11-27
11.2.4 Environmental Consequences/Environmental Impacts of the No Action/No Project Alternative 11-30
11.2.5 Environmental Consequences/Environmental Impacts of the Flexible Purchase Alternative 11-31
11.2.6 Environmental Consequences/Environmental Impacts of the Fixed Purchase Alternative 11-52
11.2.7 Comparative Analysis of Alternatives 11-56
11.2.8 Cumulative Effects 11-60
11.3 References 11-62

Chapter 12 Agricultural Social Issues 12-1
12.1 Affected Environment/Existing Conditions 12-1
12.1.1 Area of Analysis 12-1
12.1.2 Community Stability 12-2
12.1.3 Regional Community Stability 12-4
12.1.4 Environmental Measures Incorporated into the Project Description 12-5
12.1.5 Upstream from the Delta Region 12-5
12.1.6 Export Service Area 12-6
12.1.7 Characteristics of Farm Laborers 12-7
12.2 Environmental Consequences/Environmental Impacts 12-9
12.2.1 Assessment Methods 12-9
12.2.2 Environmental Consequences/Environmental Impacts of the No Action/No Project Alternative 12-10
12.2.3 Environmental Consequences/Environmental Impacts of the Flexible Purchase Alternative 12-10
12.2.4 Environmental Consequences/Environmental Impacts of Fixed Purchase Alternative 12-16
12.2.5 Comparative Analysis of Alternatives 12-17
12.2.6 Cumulative Effects 12-20
12.3 References 12-21

Chapter 13 Agricultural Land Use 13-1
13.1 Affected Environment/Existing Conditions 13-1
13.1.1 Area of Analysis 13-1
13.1.2 Land Resource Protection Programs 13-2
13.1.3 Upstream from the Delta 13-5
13.1.4 Export Service Area 13-13
13.2 Environmental Consequences/Environmental Impacts 13-18
13.2.1 Assessment Methods 13-18
13.2.2 Significance Criteria 13-18

13.2.3 Environmental Consequences/Environmental Impacts of the No Action/No Project Alternative 13-18
13.2.4 Environmental Consequences/Environmental Impacts of the Flexible Purchase Alternative 13-19
13.2.5 Environmental Consequences/Environmental Impacts of Fixed Purchase Alternative 13-22
13.2.6 Comparative Analysis of Alternatives 13-23
13.2.7 Mitigation Measures 13-25
13.2.8 Potentially Significant Unavoidable Impacts 13-25
13.2.9 Cumulative Effects 13-25
13.3 References 13-26

Chapter 14 Recreation Resources 14-1
14.1 Affected Environment/Existing Conditions 14-1
14.1.1 Area of Analysis 14-1
14.1.2 Upstream from the Delta Region 14-2
14.1.3 Delta 14-9
14.1.4 Export Service Area 14-10
14.2 Environmental Consequences/Environmental Impacts 14-14
14.2.1 Assessment Methods 14-14
14.2.2 Significance Criteria 14-14
14.2.3 Environmental Consequences/Environmental Impacts of the No Action/No Project Alternative 14-15
14.2.4 Environmental Consequences/Environmental Impacts of the Flexible Purchase Alternative 14-15
14.2.5 Environmental Consequences/Environmental Impacts of the Fixed Purchase Alternative 14-33
14.2.6 Comparative Analysis of Alternatives 14-38
14.2.7 Mitigation Measures 14-43
14.2.8 Potentially Significant Unavoidable Impacts 14-44
14.2.9 Cumulative Effects 14-44
14.3 References 14-45

Chapter 15 Flood Control 15-1
15.1 Affected Environment/Existing Conditions 15-1
15.1.1 Area of Analysis 15-1
15.1.2 Upstream from the Delta Region 15-2
15.1.3 Delta 15-2
15.1.4 Export Service Area 15-8
15.2 Environmental Consequences/Environmental Impacts 15-9
15.2.1 Assessment Methods 15-9
15.2.2 Significance Criteria 15-10
15.2.3 Environmental Consequences/Environmental Impacts of the No Action/No Project Alternative 15-10

15.2.4 Environmental Consequences/Environmental Impacts of the Flexible Purchase Alternative 15-10
15.2.5 Environmental Consequences/Environmental Impacts of the Fixed Purchase Alternative 15-19
15.2.6 Comparative Analysis of Alternatives 15-23
15.2.7 Mitigation Measures 15-26
15.2.8 Potentially Significant Unavoidable Impacts 15-26
15.2.9 Cumulative Effects 15-26
15.3 References 15-27

Chapter 16 Power 16-1
16.1 Area of Analysis 16-2
16.2 Affected Environment/Existing Conditions 16-4
16.2.1 CVP Hydropower System 16-4
16.2.2 SWP Hydropower System 16-5
16.2.3 Other Hydroelectric Facilities 16-6
16.2.4 Seasonal Variation of Pumping and Generation 16-6
16.2.5 Upstream from the Delta Region 16-7
16.2.6 Sacramento-San Joaquin Delta Region 16-12
16.2.7 Export Service Area 16-13
16.2.8 Regulatory Setting 16-15
16.3 Environmental Consequences/Environmental Impacts 16-16
16.3.1 Assessment Methods 16-16
16.3.2 Significance Criteria 16-16
16.3.3 Environmental Consequences/Environmental Impacts of the No Action/No Project Alternative 16-17
16.3.4 Environmental Consequences/Environmental Impacts of the Flexible Purchase Alternative 16-17
16.3.5 Regional Water Purchase Areas 16-26
16.3.6 Export Service Area 16-27
16.3.7 Environmental Consequences/Environmental Impacts of the Fixed Purchase Alternative 16-28
16.3.8 Comparative Analysis of Alternatives 16-28
16.3.9 Mitigation Measures 16-29
16.3.10 Potentially Significant Unavoidable Impacts 16-29
16.3.11 Cumulative Effects 16-36
16.4 References 16-36

Chapter 17 Cultural Resources 17-1
17.1 Affected Environment/Existing Conditions 17-1
17.1.1 Area of Analysis 17-3
17.1.2 Upstream from the Delta Region 17-4
17.1.3 Delta Region 17-8
17.1.4 Export Service Area 17-9

17.2 Environmental Consequences/Environmental Impacts....17-11
17.2.1 Assessment Methods....17-11
17.2.2 Significance Criteria....17-15
17.2.3 Environmental Incorporated into the Project Description....17-15
17.2.4 Environmental Consequences/Environmental Impacts of the No Action/No Project Alternative....17-16
17.2.5 Environmental Consequences/Environmental Impacts of the Flexible Purchase Alternative....17-17
17.2.6 Environmental Consequences/Environmental Impacts of the Fixed Purchase Alternative....17-23
17.2.7 Comparative Analysis of Alternatives....17-26
17.2.8 Mitigation Measures....17-30
17.2.9 Potentially Significant and Unavoidable Impacts....17-30
17.2.10 Cumulative Effects....17-30
17.3 References....17-31

Chapter 18 Visual Resources....18-1
18.1 Affected Environment/Existing Conditions....18-1
18.1.1 Area of Analysis....18-1
18.1.2 Upstream from the Delta Region....18-2
18.1.3 Delta....18-6
18.1.4 Export Service Areas....18-7
18.2 Environmental Consequences/Environmental Impacts....18-9
18.2.1 Assessment Methods....18-9
18.2.2 Significance Criteria....18-10
18.2.3 Environmental Consequences/Environmental Impacts of the No Action/No Project Alternative....18-10
18.2.4 Environmental Consequences/Environmental Impacts of the Flexible Purchase Alternative....18-11
18.2.5 Environmental Consequences/Environmental Impacts of the Fixed Purchase Alternative....18-18
18.2.6 Comparative Analysis of Alternative....18-23
18.2.7 Mitigation Measures....18-31
18.2.8 Potentially Significant Unavoidable Impacts....18-31
18.2.9 Cumulative Effects....18-31
18.3 References....18-32

Chapter 19 Environmental Justice....19-1
19.1 Affected Environment/Existing Conditions....19-2
19.1.1 Area of Analysis....19-5
19.1.2 Upstream from the Delta Region....19-5
19.1.3 Export Service Area....19-6
19.2 Environmental Consequences/Environmental Impacts....19-7
19.2.1 Assessment Methods....19-7

19.2.2 Criteria for Determining Adverse Effects 19-8
19.2.3 Environmental Consequences/Environmental Impacts of the No Action/No Project Alternative....19-8
19.2.4 Environmental Consequences/Environmental Impacts of the Flexible Purchase Alternative....19-9
19.2.5 Environmental Consequences/Environmental Impacts of the Fixed Purchase Alternative....19-12
19.2.6 Comparative Analysis of Alternatives....19-15
19.2.7 Cumulative Effects....19-17
19.3 References....19-18

Chapter 20 Indian Trust Assets....20-1
20.1 Affected Environment/Existing Conditions....20-2
20.1.1 Area of Analysis....20-3
20.2 Environmental Consequences/Environmental Impacts....20-4
20.2.1 Assessment Methods....20-4
20.2.2 Significance Criteria....20-5
20.2.3 Environmental Measures Incorporated into the Project Description....20-6
20.2.4 Environmental Consequences/Environmental Impacts of the No Action/No Project Alternative....20-6
20.2.5 Environmental Consequences/Environmental Impacts of the Flexible Purchase Alternative....20-9
20.2.6 Environmental Consequences/Environmental Impacts of the Fixed Purchase Alternative....20-10
20.2.7 Comparative Analysis of Alternatives....20-11
20.2.8 Mitigation Measures....20-13
20.2.9 Potentially Significant and Unavoidable Impacts....20-13
20.2.10 Cumulative Effects....20-13
20.3 References....20-14

Chapter 21 Growth Inducing Impacts....21-1
21.1 Introduction....21-1
21.2 Growth Inducing Factors....21-1
21.3 Current Growth....21-1
21.4 The CALFED PEIS/EIR and Water Supply Reliability....21-2
21.5 The EWA and Water Supply Reliability....21-3
21.6 References....21-7

Chapter 22 Cumulative Effects....22-1
22.1 Cumulative Effects Methodology....22-1

22.1.1 Other Water Acquisition Programs 22-1
22.1.2 Facility Improvement Projects 22-3
22.2 Cumulative Programs and Projects 22-3
22.2.1 Other Water Acquisition Programs 22-3
22.2.2 Delta Facility Improvement Projects 22-10
22.2.3 Delta Improvement Projects Interrelationships 22-14
22.3 Incremental Contribution of the EWA to the Cumulative Condition 22-15
22.4 Summary of Cumulative Effects for Individual Resource Areas 22-15
22.4.1 Surface Water Supply and Management 22-15
22.4.2 Water Quality 22-15
22.4.3 Groundwater Resources 22-16
22.4.4 Geology, Soils, and Seismicity 22-17
22.4.5 Air Quality 22-17
22.4.6 Fisheries and Aquatic Ecosystems 22-17
22.4.7 Vegetation and Wildlife 22-18
22.4.8 Regional and Agricultural Economics 22-19
22.4.9 Agricultural Social Issues 22-19
22.4.10 Agricultural Land Use 22-19
22.4.11 Recreational Resources 22-20
22.4.12 Flood Control 22-20
22.4.13 Power Production 22-20
22.4.14 Cultural Resources 22-21
22.4.15 Visual Resources 22-21
22.4.16 Environmental Justice 22-21
22.4.17 Indian Trust Assets 22-21
22.5 Mitigation Measures 22-22
22.6 References 22-22

Chapter 23 Consultation and Coordination 23-1
23.1 Fish and Wildlife Consultation 23-1
23.1.1 Consultation to Date 23-2
23.2 Indian Trust Assets and Native American Consultation 23-3
23.2.1 Consultation to Date 23-3
23.3 National Historic Preservation Act/State Historic Preservation Officer Consultation 23-3
23.3.1 Consultation to Date 23-4
23.4 Environmental Justice 23-4
23.4.1 Consultation to Date 23-5
23.5 Public Involvement 23-5
23.5.1 Environmental Impact Statement/Report Scoping 23-5
23.5.2 Summary of Public Concerns 23-6
23.5.3 Public Review of Draft EIS/EIR 23-15

Chapter 24 List of Preparers and their Qualifications 24-1

Attachment 1 Modeling Appendix

Appendix A CALFED Bay-Delta Program Programmatic Record of Decision

Appendix B U.S. Fish & Wildlife Coordination Act Compliance

Appendix C Environmental Water Account Operating Principles Agreement

Appendix D Fish Decision Trees

Appendix E 2003 EWA Acquisition Strategy

Appendix F Notice of Preparation/Notice of Intent

Appendix G Water Quality Technical Appendix

Appendix H Graphical and Tabular Analysis of Environmental Resources

Appendix I Endangered Species Act Section 7 Compliance

Appendix J Environmental Water Account Action Specific Implementation Plan

Tables

10-1 Crosswalk of MSCS NCCP Habitat Types to Other Community and Habitat Classification Systems 10-3
10-2 River Corridor Habitats and Associated Vegetation 10-15
10-3 Wildlife, Including Special-Status Species, Associated with Rice Fields 10-24
10-4 Seasonally Flooded Agriculture Acreage and Waste Grain Reductions in Each County Based on Crop Idling Maximum Purchases under the Flexible Purchase Alternative 10-71
10-5 Relationship of Special-Status Species Associated to Rice Land Crop Cycles 10-73
10-6 Long-term Average Delta Outflow under Baseline Condition and Flexible Purchase Alternative (Maximum Water Purchase Scenario) 10-85
10-7 Long-term Average Delta X_2 Position under Baseline and Flexible Purchase Alternative (Maximum Water Purchase Scenario) 10-86
10-8 Seasonally Flooded Agriculture Acreage and Waste Grain Reductions in Each County Based on Crop Idling Maximum Purchases under the Fixed Purchase Alternative 10-100
10-9 Vegetation and Wildlife: Potential Transfer Amounts and Comparison of the Flexible and Fixed Purchase Alternatives 10-106

11-1 1999 Total Industry Earnings and Employment Upstream from the Delta Region 11-3
11-2 1999 Economic Activity Upstream from the Delta Region 11-4
11-3 Farms, Land in Farms and Cropland Profiles of Counties Upstream from the Delta Region, 1997 11-5
11-4 1999 Agricultural Revenues and Production Costs, Upstream from the Delta Region 11-6
11-5 1999 Production Expenses, Upstream from the Delta Region 11-7
11-6 Butte County Leading Commodities, 2000 11-8
11-7 Colusa County Leading Commodities, 2000 11-9
11-8 Glenn County Leading Commodities, 2000 11-10
11-9 Placer County Leading Commodities, 2000 11-11
11-10 Sutter County Leading Commodities, 2000 11-12
11-11 Yolo County Leading Commodities, 2000 11-13
11-12 1999 Total Industry Earnings and Employment in the Export Service Area 11-14
11-13 1999 Economic Activity in the Export Service Area 11-15
11-14 Farm and Cropland Profiles of Counties in the Export Service Area, 1997 11-15
11-15 1999 Agricultural Revenues and Production Costs, Export Service Area 11-16
11-16 1999 Production Expenses, Export Service Area 11-16

11-17 Fresno County Leading Commodities, 2000 11-17
11-18 Kern County Leading Commodities, 2000 11-18
11-19 Kings County Leading Commodities, 2000 11-19
11-20 Tulare County Leading Commodities, 2000 11-20
11-21 County Property Tax Revenues and Open Space Tax Relief Aid, Fiscal Year 1999-2000 11-22
11-22 Typical Agricultural Groundwater Production Costs in 1992 by Hydrologic Region 11-22
11-23 Acreage of Cotton and Rice in Counties of Interest, 1990 to 2000 11-29
11-24 Information from Other Studies Related to Socioeconomic Effects for Land Idling 11-30
11-25 Baseline Conditions – Upstream from the Delta Region, 1997 dollars 11-32
11-26 Net Revenue from Water Transfer, Lost Revenue, Variable Costs Avoided and Lost Return Over Variable Costs, 1997 dollars 11-34
11-27 Value of Output, Value Added, Wages and Salaries, and Employment - Total Effect of Idling Rice per Acre In Upstream from the Delta Region, 1997 dollars 11-35
11-28 Description of Potential EWA Rice Idling Action Upstream from the Delta Region 11-35
11-29 Upstream of Delta Region County Baseline Conditions, Million 1997 $ and Jobs 11-36
11-30 Total County Effects of Idling Rice, 1997 dollars 11-36
11-31 Economic Effects of Alternative Rice Idling Action in Counties in the Upstream from the Delta Region 11-37
11-32 Total County Effect of Idling Rice in Colusa and Glenn Counties Under Different Water Prices, 1997 11-38
11-33 Baseline Conditions – Export Service Areas, 1997 dollars 11-40
11-34 Net Revenue from Water Transfer, Lost Revenue, Variable Costs Avoided and Lost Return Over Variable Costs, Dollars per Acre, Export Service Area, 1997 dollars 11-42
11-35 Value of Output, Value Added, Wages and Salaries and Employment - Total Regional Effect of Idling Cotton, 1997 11-42
11-36 Description of EWA Cotton Idling Actions in Export Service Areas 11-43
11-37 Export Service Area County Baseline Conditions, 1997 dollars 11-43
11-38 Total County Effect of Idling Cotton, 1997 dollars 11-44
11-39 Economic Effects of Alternative Cotton Idling Actions in Export Service Area Counties 11-45
11-40 Water Purchases by Type of End User 11-49
11-41 Economic Effects of Rice Idling under the Fixed Purchase Alternative Upstream from the Delta Region 11-54
11-42 Economic Effects of Cotton Idling under the Fixed Purchase Alternative Export Service Area 11-55
11-43 Comparison of Regional and Agricultural Economic Effects of Flexible and

	Fixed Purchase Alternative Compared to the Baseline Condition	11-59
11-44	Acres of Rice Idled under Cumulative Condition	11-61
11-45	Acres of Cotton Idled under Cumulative Condition	11-61
12-1	Existing Conditions: Regional Demographics and Economic Indicators of Social Well-Being	12-4
12-2	Upstream Counties- Population, Income, Employment, and Farms	12-6
12-3	Export Service Area Counties- Population, Income, Employment and Farms	12-7
12-4	Maximum Proposed Acreages for Rice Idling for Flexible Purchase Alternative	12-11
12-5	Maximum Proposed Acreages for Cotton Idling for Flexible Purchase Alternative	12-14
12-6	Proposed Acreage for Rice Idling for Fixed Purchase Alternative	12-17
12-7	Maximum Number of Jobs Lost to Crop Idling Under Fixed Purchase and Flexible Purchase Alternative	12-19
12-8	Comparison of Maximum Effects for Flexible and Fixed Purchase Alternatives on Agricultural Social Issues	12-20
13-1	2001 Williamson Act and Farmland Security Zone Enrolled Acreages	13-2
13-2	Butte County Land Use Summary and Change by Land Use Category	13-6
13-3	Land Use Conversion from 1998 to 2000, Butte County	13-6
13-4	Colusa County Land Use Summary and Change by Land Use Category	13-7
13-5	Land Use Conversion from 1998 to 2000, Colusa County	13-7
13-6	Glenn County Land Use Summary and Change by Land Use Category	13-8
13-7	Land Use Conversion from 1998 to 2000, Glenn County	13-8
13-8	Placer County Land Use Summary and Change by Land Use Category	13-9
13-9	Land Use Conversion from 1998 to 2000, Placer County	13-10
13-10	Sutter County Land Use Summary and Change by Land Use Category	13-11
13-11	Land Use Conversion from 1998 to 2000, Sutter County	13-11
13-12	Yolo County Land Use Summary and Change by Land Use Category	13-12
13-13	Land Use Conversion from 1998 to 2000, Yolo County	13-12
13-14	Fresno County Land Use Summary and Change by Land Use Category	13-13
13-15	Land Use Conversion from 1998 to 2000, Fresno County	13-14
13-16	Kern County Land Use Summary and Change by Land Use Category	13-15
13-17	Land Use Conversion from 1998 to 2000, Kern County	13-15
13-18	Kings County Land Use Summary and Change by Land Use Category	13-16
13-19	Land Use Conversion from 1998 to 2000, Kings County	13-16
13-20	Tulare County Land Use Summary and Change by Land Use Category	13-17
13-21	Land Use Conversion from 1998 to 2000, Tulare County	13-17
13-22	Proposed Maximum Acreages for Rice Idling	13-19
13-23	Proposed Maximum Acreages for Cotton Idling	13-21
13-24	Proposed Maximum Acreages for Rice/Cotton Idling for Fixed Alternative	13-23

13-25 Comparison of Agricultural Land Use Effects for Flexible and Fixed Purchase Alternatives 13-25

14-1 Potential Recreation Effects at Castaic Lake State Recreation Area due to Changes in Surface Water Level 14-12
14-2 Lake Perris Boat Ramps 14-12
14-3 Potential Recreation Effects at Lake Perris State Recreation Area Due to Changes in Surface Water Level 14-13
14-4 Long-term Average Water Temperature in the Sacramento River below Keswick Dam Under the Baseline Condition and Flexible Purchase Alternative 14-17
14-5 Long-term Average Water Temperature in the Feather River below Thermalito Afterbay Under the Baseline Condition and Flexible Purchase Alternative 14-19
14-6 Long-term Average Water Temperature in the American River Below Nimbus Dam Under the Baseline Condition and Flexible Purchase Alternative 14-27
14-7 Comparison of the Effects of the Flexible and Fixed Purchase Alternatives Recreation Resources 14-40

15-1 Long-term Average Release from Keswick Dam 15-11
15-2 Long-term Average Flow Below Thermalito Afterbay 15-13
15-3 Long-term Average Release from Nimbus Dam 15-15
15-4 Long-term Average Flow Below Crocker-Huffman Dam 15-16
15-5 Long-term Average Delta Inflow from the Sacramento River 15-17
15-6 Long-term Average Delta Inflow from the San Joaquin River 15-18
15-7 Comparison of the Effects of the Flexible and Fixed Purchase Alternatives on Flood Control 15-24

16-1 Power Resources of the Central Valley Project 16-4
16-2 Major Pumping Plants of the Central Valley Project 16-5
16-3 Major Power Plants of the State Water Project 16-6
16-4 Major Pumping Plants of the State Water Project 16-6
16-5 Shasta/Keswick Average Monthly Generation 16-18
16-6 Oroville/Thermalito Average Monthly Generation 16-19
16-7 Folsom/Nimbus Average Monthly Generation 16-20
16-8 Simulated Average Monthly Combined Export Pumping at Banks and Tracy (1979-93) 16-24
16-9 Simulated Average Combined Export Pumping Costs at Banks and Tracy (1979-93) 16-25
16-10 Potential Transfer Amounts and Comparison of the Flexible and Fixed Purchase Alternatives for Power Resources 16-30

17-1 Historic Lower Bounds of Reservoir Surface Elevations 17-16
17-2 Comparison of Impacts on Cultural Resources for Flexible and Fixed Purchase Alternatives 17-27

18-1 Comparison of the Effects of the Flexible and Fixed Purchase Alternatives on Visual Resources 18-25

19-1 Labor and Water Requirements per Common Crop 19-3
19-2 Ethnicities by Region 19-4
19-3 Average Poverty and Unemployment Levels 19-5
19-4 Ethnicities in Upstream from the Delta Counties 19-5
19-5 County Demographics – Upstream from the Delta 19-6
19-6 Ethnicities in Export Service Area 19-6
19-7 County Demographics – Export Service Area 19-6
19-8 Proposed Acreages for Rice Idling –Upstream Areas Flexible Purchase Alternative 19-9

Chapter 10
Vegetation and Wildlife

For an area of its size, California has one of the greatest diversities of natural areas and flora and fauna in North America. California's topography, climate, and soil types provide for a variety of microhabitats and a high degree of endemism - approximately 24 percent of California's plants and a large number of its animals are native exclusively to California (Hickman 1993). Section 10.1 details the existing conditions of the EWA area of analysis. Section 10.2 details the effects of EWA actions on vegetation and wildlife.

10.1 Affected Environment/Existing Conditions

This section describes the existing conditions of each region potentially affected by the EWA program. Section 3.4 provides a description of the baseline to be used for this affects analysis. The focus of this section will be on the natural and agricultural communities within each region and the wildlife associated with these communities. Fish and fisheries issues are discussed in Chapter 9. Additional information about California Endangered Species Act (CESA)/Federal Endangered Species Act (ESA) special-status species and natural community conservation plan (NCCP) communities is contained within the EWA Action Specific Implementation Plan (ASIP) being prepared by the California Department of Water Resources (DWR), the Bureau of Reclamation (Reclamation), the California Department of Fish and Game (CDFG), the U.S. Fish and Wildlife Service (USFWS), and the National Marine Fisheries Service (NOAA Fisheries). An ASIP is prepared for each CALFED action or groups of actions as they are proposed for implementation. ASIPs are designed to provide the information necessary to initiate project-level compliance with the ESA, CESA, and Natural Community Conservation Planning Act (NCCPA) (CALFED 2000c). The EWA ASIP can be found in Appendix J.

In this document and the ASIP, special-status species are defined as those threatened, endangered, or rare (in the case of plants) species provided protection under the ESA and the CESA. Also included within the special-status species designation are species of special concern based on factors such as limited distribution; declining population size; diminishing habitat acreage or value; or unusual scientific, recreational, or educational value maintained by federal and state agencies. Legal protection for species of special concern is more limited than listed species, but species of special concern may be added to official lists in the future if the decline of these species continues. Special-status species within the area of analysis and those species considered for evaluation can be found in the EWA ASIP.

The Multi-Species Conservation Strategy (MSCS), which was developed to assist entities implementing CALFED actions with ESA/CESA compliance, identifies 20 NCCP communities (18 habitats and two fish groups). The existing conditions section of this document consistency uses the 18 NCCP habitats for all described regions to

reduce confusion between this Environmental Impact Statement (EIS)/Environmental Impact Report (EIR) and the EWA ASIP. (See Table 10-1.) Using these 18 habitats also provides continuity between the EWA program and other CALFED programs.

The California GAP mapping system[1], which is based on the California Natural Diversity Database (CNDDB) classification system, and CDFG's Wetland and Riparian Classification, which is based on a combined Cowardin and National Oceanic and Atmospheric Administration (NOAA) C-CAP system[2] were used to identify habitat types surrounding water transfer facilities. Table 10-1 provides cross-references for the California GAP habitats and MSCS NCCP habitats.

Both the ESA and the NCCPA include provisions for the development of conservation plans to protect vegetation and wildlife resources. The Habitat Conservation Plan (HCP) is designed to offset any harmful effects that a proposed activity might have on a listed species. The HCP process allows development to proceed while promoting listed species conservation. An NCCP "identifies and provides for the regional or area wide protection of plants, animals, and their habitats, while also allowing appropriate development to proceed" (CDFG 2002). There are over 105 HCPs and 15 NCCPs within the State of California that have been approved or are in-progress. Because EWA actions are confined to water transfers or crop idling, the EWA Program would not violate any of these HCP's or NCCP's.

10.1.1 Area of Analysis

EWA actions would affect portions of the Central Valley, the Delta, and, to a limited extent, Southern California. However, these actions would be confined to rivers, reservoirs, and rice croplands upstream from the Delta; the waterways of the Delta; and cotton croplands, canals, and reservoirs in the Export Service Area (areas downstream from the Delta). The area of analysis, shown on Figure 10-1, illustrates the location for each river and water conveyance/storage system addressed in this EIS/EIR.

- The Sacramento River from its terminus in the Delta north to Lake Shasta;
- The Feather River from its intersection with the Sacramento River through Lake Oroville up the South Fork to Little Grass Valley Reservoir;

---

1 California Gap Analysis Program (GAP) mapping system. California GAP data under represents wetland and riparian features by using a 40-heactare (ha) (99-acre) minimum mapping unit for wetlands. Most wetland areas within the state are less than 40-ha; and would not be represented on the GAP maps. In order to adequately describe wetland and riparian habitats within the EWA action area, the DFG's Wetland and Riparian Classification maps were also used. California GAP uses a 100-ha (247-acre) minimum mapping unit for upland types (MSCS, 2000).

2 Classification of Wetlands and Deepwater Habitats of the United States, (Cowardin *et al.*, 1997) and National Oceanic and Atmospheric Administration Coastal Change Analysis Project (Dobson *et al.*, 1995)

Table 10-1
Crosswalk of MSCS NCCP Habitat Types to Other Community and Habitat Classification Systems

MSCS NCCP Habitat Type	***Equivalent Community or Habitat Type Under Other Classification Systems***				
	Ecosystem Restoration Program	***Wildlife Habitat Relationships*** [a]	***Terrestrial Natural Communities of California*** [b]	***National Wetland Inventory*** [c]	***Department of Water Resources*** [d]
Tidal perennial aquatic	Tidal perennial aquatic, Delta sloughs, and midchannel islands and shoals	Estuarine	None	Estuarine (aquatic subtypes only)	Water surface

Saline emergent	Saline emergent wetland	Saline emergent wetland	Coastal saltmarsh (52100) and coastal brackish marsh (52200)	Estuarine/emergent	Riparian vegetation: marshlands
Tidal freshwater emergent	Fresh emergent wetland, Delta sloughs, and midchannel islands and shoals	Fresh emergent wetland	Coastal and valley freshwater marsh (52410)	Palustrine/emergent/tidal	Riparian vegetation: marshlands
Nontidal freshwater permanent emergent	Fresh emergent wetland	Fresh emergent wetland and wet meadow	Freshwater marsh (52400), alkali marsh (52300), and meadow and seep (45000)	Palustrine/emergent/nontidal/ permanent; lacustrine/emergent/permanent; riverine/emergent/permanent	Riparian vegetation: marshlands; riparian vegetation: natural high-water table
Natural seasonal wetland	Seasonal wetlands	Fresh emergent wetland	Vernal pool (44000), vernal marsh (52500) and alkali playa (46000)	Palustrine/emergent/nontidal/ seasonal	None
Managed seasonal wetland	Seasonal wetlands	Fresh emergent wetland	Vernal marsh (52500)	Palustrine/emergent/nontidal/ seasonal/artificial	Riparian vegetation: duck marsh
Valley/foothill riparian	Riparian and riverine aquatic	Valley foothill riparian	Great Valley riparian forest (61400), sycamore alluvial woodland (62100) and Great Valley riparian scrub (63400)	Estuarine/scrub-shrub, estuarine/ forested, palustrine/scrub-shrub, and palustrine/forested	Riparian vegetation: trees and shrubs.
Montane riparian	Riparian and riverine aquatic	Montane riparian	Montane riparian forest (61500) and montane riparian scrub (63500)	Estuarine/scrub-shrub, estuarine/ forested, palustrine/scrub-shrub, and palustrine/forested	Riparian vegetation: trees and shrubs.
Grassland	Perennial grassland	Annual grassland and perennial grassland	Valley and foothill grassland (42000)	Upland	Native vegetation: grassland
Inland dune scrub	Inland dune scrub	None	Stabilized interior dunes (23100)	Upland	None

Table 10-1
Crosswalk of MSCS NCCP Habitat Types to Other Community and Habitat Classification Systems

MSCS NCCP Habitat Type	***Equivalent Community or Habitat Type Under Other Classification Systems***				
	Ecosystem Restoration Program	***Wildlife Habitat Relationships*** [(a)]	***Terrestrial Natural Communities of California*** [(b)]	***National Wetland Inventory*** [(c)]	***Department of Water Resources*** [(d)]
Upland scrub	None	Montane chaparral, mixed chaparral, chamise-redshank chaparral, and alkali desert scrub	Great valley chenopod scrub (36200), chaparral (37000), and Diablan sage scrub (32600)	Upland	Native vegetation: light brush, medium brush, and heavy brush
Valley/foothill woodland and forest	None	Valley oak woodland, blue oak woodland, and blue oak-foothill pine	Cismontane woodland (71000), interior live oak forest (81330)	Upland	Native vegetation: brush and timber
Montane woodland and forest	None	Sierran mixed conifer, Douglas-fir, ponderosa pine, aspen, montane hardwood conifer, and montane hardwood	Broadleaved upland forest (81000), upland Douglas fir forest (82420), and Sierran coniferous forest (84200)	Upland	None
Upland cropland	Agricultural lands	Cropland, pasture, and orchard-vineyard	None	Upland	Grain and hay crops, field crops, truck and berry crops, pasture, and idle
Seasonally flooded agriculture	Agricultural lands	Cropland	None	Palustrine/framed	Grain and hay crops, field crops, and rice

Notes: In many cases, the MSCS NCCP habitats do not directly crosswalk to other classifications. NCCP habitats may encompass several habitats from other classifications or only a portion of a habitat from another classification. Habitats from other classifications may encompass several NCCP habitats.

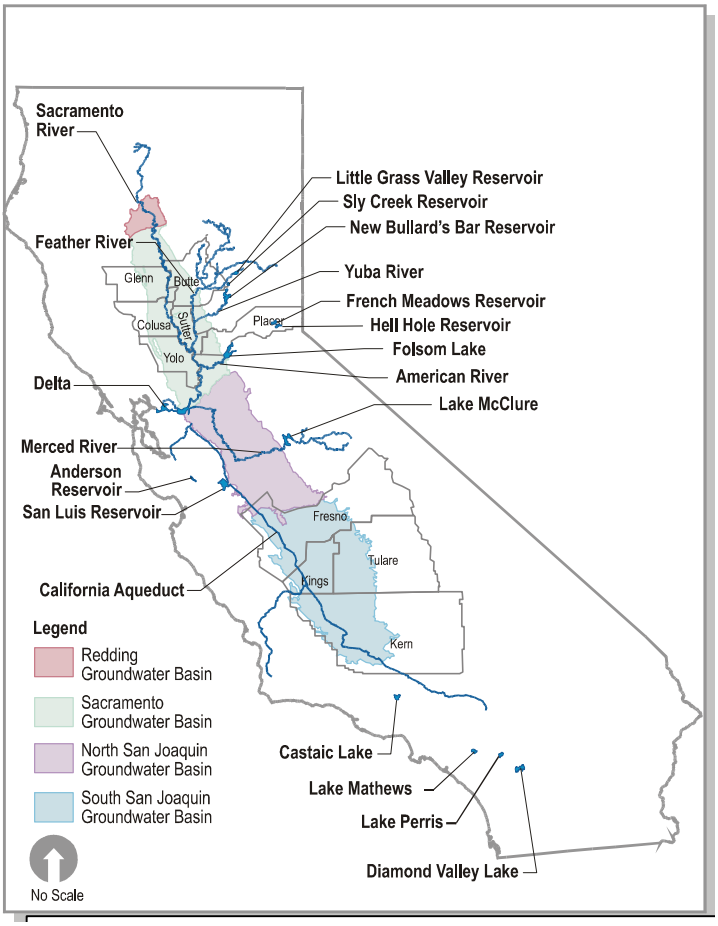

Figure 10-1
Vegetation and Wildlife Area of Analysis

- The Lost Creek from its juncture with the South Fork of the Feather River to Sly Creek Reservoir;
- The Yuba River from its intersection with the Sacramento River up to New Bullards Bar Reservoir;
- The American River from its intersection with the Sacramento River up through Lakes Natomas and Folsom to Hell Hole and French Meadows Reservoirs;
- The Merced River from its intersection with the San Joaquin River up to Lake McClure;
- The San Joaquin River from its terminus in the Delta to its intersection with the Merced River;
- Other waterways within the legal boundaries of the Delta (as described in California Water Code 12220);
- The California aqueduct and its branches from the Tracy and Banks Pumping Plants to Lake Perris and Castaic Lake;
- MWD's Diamond Valley Lake and Lake Mathews; and
- Santa Clara Valley Water District's Anderson Reservoir.

In addition, the area of analysis extends up to one mile around each river or to the flooding limits of each river whichever is greater. For reservoirs the area of analysis encompasses the reservoir itself and adjacent lands up to ¼ mile away from the reservoir. Also included are all rice and cotton fields being considered for crop idling actions and adjacent lands up to ½ mile surrounding idled fields, and wetlands and riparian habitats associated with groundwater substitution areas.

10.1.2 Upstream from the Delta

The Upstream from the Delta region includes the Sacramento and San Joaquin River watersheds, encompassing most of the Central Valley of California. Fifteen of the 18 counties within the Central Valley contain parts of these two watersheds. The Central Valley contains approximately one-fifth the land area (27,000 square miles) of the state, and once supported a variety of grassland, savannah, riparian, and wetland habitats (Lopez 1996). Today the Central Valley is predominantly agricultural, with rice, orchards, and vineyards in the northern part of the valley and cotton and citrus orchards in the southern part. Undeveloped land in the Central Valley is mostly non-native annual grasslands. However, the Central Valley still includes remnants of native perennial grassland, vernal pool wetlands, riparian, and oak woodland habitats providing the Central Valley with a diversity of habitats, which supports over 827 special-status species (USFWS 2003). The following sections detail the habitats, vegetation[3], and wildlife within the Upstream from the Delta Region.

The sections below describe the NCCP habitats within the Upstream from the Delta Region. These descriptions include the dominant vegetation, where each habitat can be found within the area of analysis, and lists of wildlife and special-status species associated with each habitat. Lists of dominant vegetation are based on the California Wildlife Habitat Relationship System; lists of wildlife are based upon searches of available literature; and lists of special-status species are based on MSCS Appendix C and the Ecosystem Restoration Program Plan.

10.1.2.1 Valley Riverine Aquatic

Valley riverine aquatic (VRA) habitat includes the water column of flowing streams and rivers in low-gradient channel reaches below an elevation of approximately 300 feet that are not tidally influenced. This includes associated shaded riverine aquatic (SRA), pool, riffle, run, and unvegetated channel substrate (including seasonally exposed channel bed) habitat features, and sloughs, backwaters, overflow channels, and flood bypasses hydrologically connected to stream and river channels. The following river systems have VRA habitat.

Sacramento River

VRA habitat on the Sacramento River extends from approximately the legal limits of the Delta (Sacramento River at the I Street bridge) to the vicinity of Red Bluff, California (approximately 300 feet above mean sea level [amsl]).

Feather River

VRA habitat on the Feather River extends from the juncture of the Sacramento and Feather Rivers up to Oroville, CA.

---

[3] The California Wildlife Habitat Relationship System (2002) has been used to determine the dominant vegetation and wildlife for each habitat type.

Yuba River
VRA habitat on the Yuba River extends from the juncture of the Feather and Yuba rivers up to approximately Timbuctoo Bend.

American River
VRA habitat on the American River extends from the juncture of the Sacramento and American Rivers to Folsom Lake.

Merced/San Joaquin River
VRA habitat on the Merced River extends from the juncture of the Merced and San Joaquin Rivers to Merced Falls, CA. VRA habitat on the San Joaquin River in the EWA area of analysis extends from the juncture of the Merced and San Joaquin Rivers into the Delta.

10.1.2.1.1 Vegetation
The dominant vegetation of valley riverine aquatic habitat includes plankton, water moss, algae, and duckweed.

10.1.2.1.2 Wildlife
Aquatic species include riffle insects such as the nymphs of caddisflies, mayflies, alderflies, and stoneflies; pool insects such as dragonflies, damselflies, and water striders; and mollusks, crustaceans, diving beetles, water boatmen. Avian species associated with VRA habitat include waterfowl, wading birds, shorebirds, and raptors. Example species include gulls, terns, herons, kingfisher, swallows, swifts, and flycatchers. Mammal species associated with VRA include river otter, muskrat, and beaver.

10.1.2.1.3 Special-Status Species
Special-status animal and plant species associated with VRA include bald eagle, bank swallow, osprey, western pond turtle, California red-legged frog, foothill yellow-legged frog, and eel-grass pondweed.

10.1.2.2 Montane Riverine Aquatic
Montane riverine aquatic (MRA) habitat includes the water column of flowing streams and rivers above an elevation of approximately 300 feet. This includes associated SRA, pool, riffle, run, and unvegetated channel substrate (including seasonally exposed channel bed) habitat features, and sloughs, backwaters, and overflow channels hydrologically connected to stream and river channels. The following river systems have developed MRA habitat.

Sacramento River
MRA habitat on the Sacramento River extends from Red Bluff, CA to Lake Shasta.

Feather River
MRA habitat on the Feather River extends between Oroville, CA and Lake Oroville, and then continues from Lake Oroville to Little Grass Valley Reservoir. MRA habitat can also be found along Lost Creek from its juncture with the Feather River to Sly

Creek Reservoir. However, water transfers occurring within this area of analysis would take place through tunnels developed by power companies and not in the natural rivers and creeks.

Yuba River
MRA habitat on the Yuba River in the EWA area of analysis extends from approximately Timbuctoo Bend to New Bullards Bar Reservoir.

American River
MRA habitat on the American River in the EWA area of analysis extends from approximately Folsom Lake to French Meadows Reservoir.

Merced/San Joaquin River
MRA habitat on the Merced River in the EWA area of analysis extends from Merced Falls, CA through Lake McSwain to Lake McClure.

10.1.2.2.1 Vegetation
The dominant vegetation for montane riverine aquatic habitat is the same as for valley riverine aquatic (plankton, water moss, algae, and duck weed).

10.1.2.2.2 Wildlife
The wildlife associated with montane riverine aquatic habitat is similar to valley riverine aquatic habitat species.

10.1.2.2.3 Special-Status Species
Special-status animal and plant species associated with MRA habitats include bald eagle, osprey, western pond turtle, California red-legged frog, foothill yellow-legged frog, California freshwater shrimp, and eel-grass pondweed.

10.1.2.3 Lacustrine
Lacustrine habitat is defined as portions of permanent bodies of water that do not support emergent vegetation and that are not subject to tidal exchange, including lakes, ponds, oxbows, gravel pits, and flooded islands.

When water levels are low, exposed shorelines (drawdown zones) are a common feature of reservoirs, and include rocky, sandy, or silty substrates. Aside from ruderal species, these areas are usually devoid of vegetation because of the inundation/desiccation cycle associated with fluctuating reservoir water levels (Entrix 1996). The following river systems have areas of lacustrine habitat.

Sacramento River
Lacustrine habitat along the Sacramento River includes Lake Shasta and Keswick Reservoir. In addition, historical meandering by the Sacramento River has created remnant oxbow and floodplain lakes within the area of analysis.

Feather River
Lacustrine habitat along the Feather River includes Little Grass Valley and Sly Creek Reservoirs, Lake Oroville, and the Thermalito Afterbay. As with the Sacramento

River, historical meandering by the Feather River has created remnant oxbow and floodplain lakes within the area of analysis.

Yuba River
Lacustrine habitat along the Yuba River includes New Bullards Bar Reservoir and Englebright Lake.

American River
Lacustrine habitat along the American River includes French Meadows and Hell Hole Reservoirs and Folsom Lake and Lake Natoma. Historical meandering by the American River has created remnant oxbow and floodplain lakes within the Lower American River area of analysis.

Merced/San Joaquin River
Lacustrine habitat along the Merced and San Joaquin Rivers within the area of analysis includes Lakes McClure and McSwain.

10.1.2.3.1 Vegetation
Plankton, water lilies, duckweed, pondweed, and smartweeds are the dominant vegetation for lacustrine habitats.

10.1.2.3.2 Wildlife
Lacustrine habitats are used by mammals, birds, reptiles, and amphibians for reproduction, food, water, and cover (Grenfell Jr. 2003). For example, bird species observed foraging over Lake Oroville include the barn swallow, western grebe, and great blue heron.

10.1.2.3.3 Special-Status Species
Special-status animal and plant species associated with lacustrine habitats include bald eagle, Aleutian Canada goose, California gull, osprey, western pond turtle, California red-legged frog, and eel-grass pondweed.

10.1.2.4 Nontidal Freshwater Permanent Emergent
Nontidal freshwater permanent emergent habitat (NFPE) includes permanent (natural and managed) wetlands, including meadows, dominated by wetland plant species that are not tolerant of saline or brackish conditions. The following river systems have developed areas of NFPE habitat.

Sacramento River
NFPE habitat can be found scattered along the Sacramento River typically in areas with slow moving backwaters. Substantial portions of these habitats occur at the Colusa, Sutter, and Tisdale Bypasses, the Butte Sink, and at the Fremont Weir.

Feather River
NFPE habitat can be found scattered along the Feather River typically in areas with slow moving backwaters. The Oroville Wildlife Area supports this habitat around its quarry ponds. Other areas include the Feather River Wildlife Area.

Yuba River
NFPE habitat can be found scattered along the Feather River typically in areas with slow moving backwaters.

American River
NFPE habitat can be found scattered along the Feather River typically in areas with slow moving backwaters.

Merced/San Joaquin River
NFPE habitat can be found scattered along the Feather River typically in areas with slow moving backwaters. The Dredger Tailings reach supports approximately 28 acres of remnant marsh (approximately half of all remnant marsh in the river corridor) (Stillwater Sciences 2002).

10.1.2.4.1 Vegetation

The dominant vegetation for nontidal freshwater permanent emergent includes thingrass, spikerush, big leaf sedge, bulrush, redroot nutgrass, tules, cattails, common reed, and water grass.

10.1.2.4.2 Wildlife

Freshwater emergent wetlands are among the most productive wildlife habitats in California. They provide food, cover, and water for more than 160 species of birds and numerous mammals, reptiles, and amphibians (Kramer 2003). Examples of amphibians include bullfrogs, western toads, and Pacific tree frogs. Birds include herons, egrets, bitterns, merganser, wood duck, and yellow warbler.

10.1.2.4.3 Special-Status Species

Special-status animal species associated with NFPE habitats include Aleutian Canada goose, American peregrine falcon, black-crowned night heron, black tern, black rail, California gull, greater sandhill crane, long-billed curlew, northern harrier, short-eared owl, snowy egret, tricolored black bird, western least bittern, white-faced ibis, white-tailed kite, giant garter snake, western pond turtle, and California red-legged frog.

Special-status plants include Ferris' milk vetch, bristly sedge, Hispid bird's beak, four-angled spikerush, Delta coyote thistle, rose-mallow, California beaked-rush, Sanford's arrowhead, marsh skullcap, mad-dog skullcap, marsh checkerbloom, and Kenwwod marsh checkerbloom.

10.1.2.5 Natural Seasonal Wetland

Natural seasonal wetland (NSW) habitat includes vernal pools and other nonmanaged seasonal wetlands with natural hydrologic conditions that are dominated by herbaceous vegetation and that annually pond surface water or maintain saturated soils at the ground surface for enough of the year to support facultative or obligate wetland plant species. Alkaline and saline seasonal wetlands that were not historically part of a tidal regime are included in natural seasonal wetlands.

Sacramento River
NSW habitat can be found scattered along the Sacramento River typically in areas with slow moving backwaters. Substantial portions of these habitats occur at the Colusa, Sutter, and Tisdale Bypasses, the Butte Sink, and at the Fremont Weir.

Feather River
NSW habitat can be found scattered along the Feather River typically in areas with slow moving backwaters.

Yuba River
NSW habitat can be found scattered along the Yuba River typically in areas with slow moving backwaters.

American River
NSW habitat can be found scattered along the American River typically in areas with slow moving backwaters.

Merced/San Joaquin River
NSW habitat can be found scattered along the Merced/San Joaquin River typically in areas with slow moving backwaters.

10.1.2.5.1 Vegetation
Dominant natural seasonal wetland vegetation includes big leaf sedge, bulrush, and redroot nutgrass.

10.1.2.5.2 Wildlife
Wildlife associated with natural seasonal wetlands are predominantly special-status species. Common species can include ducks, geese, heron, and other waterfowl, wading, and shorebirds.

10.1.2.5.3 Special-Status Species
Special-status animal species associated with NSW include American peregrine falcon, California gull, greater sandhill crane, long-billed curlew, northern harrier, short-eared owl, Swainson's hawk, tricolored blackbird, white-tailed kite, giant garter snake, California red-legged frog, California tiger salamander, western spadefoot toad, conservancy fairy shrimp, Delta green ground beetle, longhorn fairy shrimp, mid-valley fairy shrimp, vernal pool fairy shrimp, and vernal pool tadpole shrimp.

Special-status plant species associated with NSW include Henderson's bentgrass, Ferris' milkvetch, alkali milk vetch, heartscale, brittlescale, San Joaquin spearscale, lesser saltscale, succulent owl's clover, Hoover's spurge, Hispid bird's beak, palmate-bracted bird's beak, recurved larkspur, Boggs Lake hedge-hyssop, Ahart's dwarf rush, Contra Costa goldfields, Legenere, Heckard's peppergrass, Butte County meadowfoam, pincushion navarretia, Colusa grass, San Joaquin Valley orcutt grass, hairy orcutt grass, slender orcutt grass, Sacramento orcutt grass, Ahart's paronychia, and Greene's tuctoria.

10.1.2.6 Managed Seasonal Wetland

Managed seasonal wetland (MSW) habitat includes wetlands dominated by native or non-native herbaceous plants, excluding croplands farmed for profit (e.g., corn and rice), that land managers flood and drain during specific periods to enhance habitat values for specific wildlife species. Ditches and drains associated with managed seasonal wetlands are included in this habitat type.

Sacramento River

Managed seasonal wetlands on west side of the Sacramento River generally occur between Willows and Dunnigan, CA along the Colusa Main Drain. Substantial portions of these habitats also occur at the Colusa, Sutter (including the Sutter Bypass Wildlife Area), Tisdale, and Yolo (including the Yolo Bypass Wildlife Area) Bypasses, at the Fremont Weir, and as a part of the Sacramento National Wildlife Refuge Complex (six refuges totaling 35,000 acres).

Feather River

MSW habitat between the Sacramento River and the Feather River generally occur along Butte Creek in the Butte Basin (Upper Butte Basin and Gray Lodge Wildlife Areas), around the Thermalito Afterbay, along the Feather River downstream of Oroville, CA, and along Angel Slough north of Butte City, CA (Llano Seco Rancho Wildlife Area).

Yuba River

MSW habitat generally occurs north of the Yuba River, and around Dry Creek and the Bear River.

Merced/San Joaquin River

MSW habitat along the Merced and San Joaquin Rivers generally occurs just south of the juncture of the two rivers and is described as a part of the Export Service Area.

10.1.2.6.1 Vegetation

Dominant managed seasonal wetland habitats can include the same vegetation as for natural seasonal wetlands.

10.1.2.6.2 Wildlife

MSW habitats are often managed for waterfowl such as mallards, pintails, American widgeon, and Canada and other geese. MSW habitats also support a variety of wading and shorebirds, such as herons, egrets, terns, and gulls.

10.1.2.6.3 Special-Status Species

Special-status animal species associated with MSW include Aleutian Canada goose, American peregrine falcon, bald eagle, black tern, California gull, greater sandhill crane, long-billed curlew, northern harrier, short-eared owl, Swainson's hawk, tricolored blackbird, western snowy plover, white-faced ibis, white-tailed kite, giant garter snake, western pond turtle, California red-legged frog, and vernal pool tadpole shrimp.

Special-status plant species associated with MSW are often the same as those species found in natural seasonal wetlands.

10.1.2.7 Valley/Foothill Riparian

Valley/foothill riparian (VFR) habitat includes all successional stages of woody vegetation, commonly dominated by willow, Fremont cottonwood, valley oak, or sycamore, within the active and historical floodplains of low-gradient reaches of streams and rivers generally below an elevation of 300 feet. The following river systems and their tributaries have developed VFR habitat.

Sacramento River

South of Red Bluff, the Sacramento River enters the Sacramento Valley and transitions into Valley Riverine Aquatic and Valley/Foothill Riparian habitat. Along most of the Sacramento River and its tributaries, remnants of riparian communities are all that remain of once very productive and extensive riparian areas. Between Red Bluff and Chico, the river is mostly unleveed and contains substantial remnants of the Sacramento Valley's riparian forests. One of the most important factors, other than agriculture, affecting riparian habitat downstream of Chico Landing is the Sacramento River Flood Control Project constructed by the US Army Corps of Engineers (Sacramento River Advisory Council 2001). (See Chapter 15, Flood Control, for a more detailed description of the Sacramento River Flood Control Project.) The flood control project has confined riparian vegetation to a narrow band between the river and the riverside of the levees.

Natural areas within this reach include the Redding Arboretum and Kutras River Access; the largely riparian, Anderson River Park owned by CDFG; the Woodson Bridge State Recreation Area; the Bidwell-Sacramento River State Park; the Colusa-Sacramento River State Recreation Area; and the Sacramento River Wildlife Area.

Feather River

The Oroville Wildlife Area supports VFR habitat and represents the largest acreage of cottonwood forests along the lower Feather River. The Feather River Wildlife Area also supports VFR habitat.

Yuba River

VFR habitat on the Yuba River extends from the juncture of the Sacramento and Yuba Rivers up to approximately Timbuctoo Bend. "Deposition of hydraulic mining debris, subsequent dredge mining, and loss/confinement of the active river corridor and floodplain of the lower Yuba River since the mid-1800's probably eliminated much of the riparian vegetation along the lower Yuba River. However, since completion of New Bullard's Bar Reservoir, higher, more stable flows during the growing season appear to have increased the linear extent of riparian vegetation along the lower Yuba River" (Reclamation 2001).

American River

VFR habitat on the American River extends from the juncture of the Sacramento and American Rivers to Folsom Lake. The U.S. Fish and Wildlife Service (1991b)

estimated that approximately 3,530 acres of riparian scrub shrub and riparian forest occurs along the American River.

Merced/San Joaquin River

VFR habitat on the Merced River extends from the juncture of the Merced and San Joaquin Rivers to Merced Falls, CA. VFR habitat on the San Joaquin River in the EWA area of analysis extends from the juncture of the Merced and San Joaquin Rivers into the Delta. Approximately 3,928 acres of riparian vegetation currently exist along the Merced River, most within three miles of the confluence with the San Joaquin River. As with all Central Valley Rivers, the Merced River has been affected by agriculture, resource extraction, flow regulation and bank revetment. These actions have altered the hydrology and geomorphology of the river, in turn affecting riparian vegetation. "Consequently, existing mature forest stands along the Merced River may be unsustainable relicts of pre-dam hydrologic regimes" (Stillwater Sciences 2002).

10.1.2.7.1 Vegetation

Riparian forest systems include riparian forest successional stages, gravel bars and bare cut banks, shady vegetated banks, and sheltered wetlands such as sloughs, side channels, and oxbow lakes (Sacramento River Advisory Council 2001). Figure 10-2 shows the typical succession pattern for these communities. Other plant communities found in conjunction with riparian forests include valley oak woodland, wetland, and non-native grassland. Table 10-2 lists vegetation associated with the habitats of river corridors.

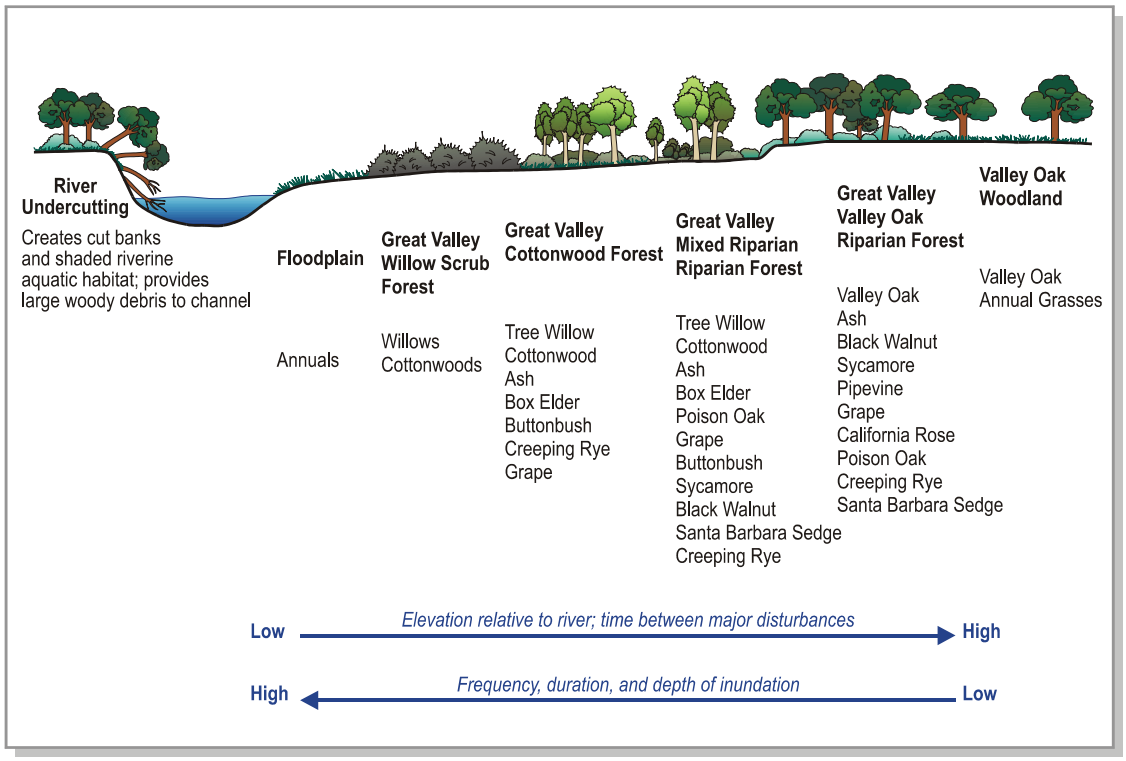

Figure 10-2
Typical Riparian Cross-section

Table 10-2
River Corridor Habitats and Associated Vegetation

Riparian Habitat	*Common Vegetation*	*Location*	*Hydrology*
Gravel bars	Willows	Active channel	Frequently indundated throughout the year
Bare cut banks	None	Riverbanks of the active channel	Repeatedly disturbed by elevated winter and spring river flows
Shady vegetated banks	Cottonwoods and willows	Riverbanks of the active channel	Repeatedly disturbed by elevated winter and spring river flows
Sloughs, side channels, oxbow lakes, backwater ponds, and wetlands	Willow, sedge, cattail, bulrush, rush, barnyard grass, slough grass, tules, and lycopus, water primrose, buttonwillow, alder, and cottonwood	Adjacent to the mainstem of a river	Connected to the river by surface water during high winter flood flows and by groundwater during other times of the year.
Willow scrub	Sandbar and other willows, cottonwoods, alder, sycamore, box elder, walnuts, Oregon ash	Point bars near the rivers edge	Repeatedly disturbed by elevated winter and spring river flows
Cottonwood forests	Cottonwood, willow, ash, box elder, butttonwillow, creeping rye, wild grape, poison oak	Narrow belts along the active river channel	Seasonal disturbance by occasional large flows
Mixed riparian forest	Cottonwood, willow, box elder, sycamore, walnut, alder, buttonwillow, blackberry, poison oak, wild grape, creeping rye, Santa Barbara sedge, elderberry	Floodplain terrace	Seasonal disturbance by occasional large flows
Valley Oak Riparian Forest	Valley oak, black walnuts, sycamore, ash, blackberry, wild grape, elderberry, grasses, sedges	Floodplain terrace; Upper terraces composed of fine sediment where soil moisture provides a long growing season	Flooded infrequently
Valley oak woodland	Valley oaks, non-native grasses	Floodplain terrace; Upper terraces composed of fine sediment where soil moisture provides a long growing season	Flooded infrequently at shallow depths
Grassland	Non-native grasses, wild rye	Found on many of the sites within the river corridor; Commonly occurs in areas that have been disturbed by human activity	Occurs in areas that are frequently flooded to those that are only indundated by exceptionally high flows at a shallow depth
Elderberry Savannah	Elderberry, grasses	Adjacent to the floodplain terrace	Only inundated by exceptionally high flows at a shallow depth

Source: SRAC 2001

Riparian plant germination, establishment, growth, and distribution is driven by water availability and floodplain and channel geomorphology. Late winter and early spring high water flows are necessary to clear the river channel of debris and vegetation and unclog sediments. These mobilized bank and riverbed sediments result in the deposition of nutrient-rich sediments on the floodplain. When timed with the release of seeds in the spring, these sediments provide suitable areas for germination of pioneer species such as cottonwood and willow. The low-flow regime, which provides freshly exposed surfaces, is the most important factor for successful seedling establishment and is critical for survival of young trees (Strahan 1985). During the summer and early fall months water availability can determine growth rates and plant types. Inundation may result in the death of young or established

pioneer species through mechanical abrasion or through lack of sufficient soil oxygen; late summer desiccation results in the death of many cottonwood and willow seedlings (Strahan 1985).

Pioneer tree species tend to be shade intolerant and have difficulty growing under a closed canopy. Therefore, other dominant tree species, such as box elder and black walnut, which have the ability to germinate and grow under the cottonwood/willow overstory, begin to succeed the pioneer species. Eventually, oak and sycamore, which are found in old stands on high terraces with the other dominants and along banks high above the river, succeed the intermediate species establishing a later stage successional community (Strahan 1985).

River regulation in California's Central Valley has created artificially stable inter- and intra-annual hydrological conditions that have impaired recruitment and altered the age structure of native riparian tree populations that have evolved with pre-regulation cycles of flooding and summer drought (Stella, et. al. 2003). Changes in hydrology have caused an overall decline in bank erosion rates and an accompanying decrease in point bar formation. Fewer suitable sites for cottonwood and willow forest regeneration are now available, changing the pattern of riparian forest succession. For example, in the absence of river processes on the Lower American River such as new gravel and sand bar formation, and in combination with increased summer flows, cottonwood recruitment has been virtually eliminated and existing stands appear to be aging without opportunities for replacement. Instead alders have increased in abundance by taking advantage of the more consistent summer flows and increased bank stability (USFWS 1991b). On the Sacramento River, controlled flows have resulted in a higher survival percentage through lack of scouring and a continual provision of moisture reducing losses from desiccation (Strahan 1985).

Also affected by changes in hydrology is the inundation frequency along rivers. The frequency of overbank flooding required for natural establishment, maturation, and regeneration of the later stage successional forests continually affects smaller and smaller land areas. According to the Sacramento River Advisory Council (2001), another factor in reduced riparian forests along rivers is conversion of the land to agricultural practices.

10.1.2.7.2 Wildlife

More than 60 percent of all vertebrates spend some portion of their life cycle in riparian habitat (Reclamation and SJRG 1999). In California over 225 species of birds, mammals, reptiles, and amphibians depend on riparian habitats, and cottonwood-willow riparian areas support more breeding avian species than any other comparable broad California habitat type (Sacramento River Advisory Council 2001and Stillwater Sciences 2002). Riparian areas also serve as a corridor for wildlife movement, providing access to additional seasonal food sources and new territories for dispersing young, and allowing for the movement of individuals into and out of areas, thus ensuring a good mix of genetic material into a population (Sacramento River Advisory Council 2001).

Some of the riparian habitat has a lush canopy with associated shade and cover, which provides habitat for a myriad of insects. Rough ever-sloughing bark of common riparian trees attracts wood-boring larvae and provides forage for bark-gleaning and trunk-scaling birds. Woodpeckers, warblers, flycatchers, and owls are common inhabitants of this habitat. The tall trees also attract wintering and breeding raptors (Reclamation and SJRG 1999). Other wildlife that use riparian habitats include California towhee, Bewick's wren, belted kingfisher, scrub jay, rufous-sided towhee, blue grosbeak, tree swallow, yellow-rumped warbler, lazuli bunting, western tanager, northern oriole, western fence lizard, Pacific tree frog, western toad, bullfrog, western skink, western whiptail, southern alligator lizard, racer, gopher snake, king snake, garter snake, rattlesnake, opossum, black-tailed hair, western gray squirrel, ringtail, river otter, striped skunk, raccoon, beaver, a number of bat species, and mule deer.

10.1.2.7.3 Special-Status Species

Special-status animal species associated with VFR habitat include greater western mastiff bat, ringtail, riparian brush rabbit, San Joaquin Valley woodrat, western yellow-billed cuckoo, bank swallow, bald eagle, black-crowned night heron, California yellow warbler, Cooper's hawk, double-crested cormorant, golden eagle, great blue heron, great egret, least bell's vireo, little willow flycatcher, long-eared owl, osprey, snowy egret, Swainson's hawk, white-tailed kite, yellow-breasted chat, giant garter snake, western pond turtle, California red-legged frog, foothill yellow-legged frog, and valley elderberry longhorn beetle.

Special-status plant species include silky cryptantha, Delta coyote-thistle, marsh checkerbloom, fox sedge, rose-mallow, northern California black walnut, and Sanford's arrowhead.

10.1.2.8 Montane Riparian

Montane riparian (MR) habitat includes all successional stages of woody vegetation, such as willow, black cottonwood, white alder, birch, and dogwood, within the active floodplains of moderate-to-high-gradient reaches of streams and rivers generally above an elevation of 300 feet. The following rivers have developed MR habitat.

Sacramento River

MR habitat occurs along the Sacramento River between Red Bluff, CA and Lake Shasta.

Feather River

MR habitat on the Feather River extends between Oroville, CA and Lake Oroville, and then continues from Lake Oroville to Little Grass Valley Reservoir. MRA habitat can also be found along Lost Creek from its juncture with the Feather River to Sly Creek Reservoir. However, water transfers occurring within this area of analysis would take place through tunnels developed by power companies and not in the natural rivers and creeks.

Yuba River
MR habitat on the Yuba River in the EWA area of analysis extends from approximately Timbuctoo Bend to New Bullards Bar Reservoir.

American River
MR habitat on the American River in the EWA area of analysis extends from approximately Folsom Lake to French Meadows Reservoir.

Merced/San Joaquin River
MR habitat on the Merced River in the EWA area of analysis extends from Merced Falls, CA through Lake McSwain to Lake McClure.

10.1.2.8.1 Vegetation

Montane Riparian habitat vegetation is dominated by cottonwood (black and Fremont [at lower altitudes]), white alder, big leaf maple, dogwood, box elder, quaking aspen, wild azalea, water birch, and buttonwillow trees.

10.1.2.8.2 Wildlife

As with VFR a wide variety of wildlife is supported by riparian habitats.

10.1.2.8.3 Special-Status Species

Special-status species associated with MR habitat include California wolverine, greater western mastiff bat, ringtail, bald eagle, black-crowned night heron, California yellow warbler, Cooper's hawk, double-crested cormorant, great blue heron, great egret, least bell's vireo, little willow flycatcher, long-eared owl, osprey, snowy egret, yellow-breasted chat, California red-legged frog, foothill yellow-legged frog, silky cryptantha, valley elderberry longhorn beetle, and saw-toothed lewisia.

10.1.2.9 Grassland

Grassland habitat includes upland vegetation communities dominated by introduced and native annual and perennial grasses and forbs, including non-irrigated and irrigated pasturelands.

Grassland communities in the Central Valley are primarily confined to the western and eastern margins of the valley.

Sacramento River
Grassland habitats can also be found on the north side of Lake Shasta.

Feather River
The Oroville and Feather River Wildlife Areas downstream of Lake Oroville support grassland habitats.

American River
Grassland habitats can be found along portion s of the Folsom Lake shoreline.

Merced/San Joaquin Rivers
Grassland habitats can be found around portions of Lakes McClure and McSwain.

10.1.2.9.1 Vegetation

Grasslands in California are dominated by wild oats, soft chess, brome, ryegrass, mustard, foxtail, California oatgrass, hairgrass, sweet vernalgrass, and barley. Common forbs include filaree, clover, popcorn flower, and mullein.

10.1.2.9.2 Wildlife

Grassland wildlife include western fence lizard, common garter snake, western rattlesnake, black-tailed jackrabbit, California ground squirrel, Botta's pocket gopher, harvest mouse, California vole, badger, and coyote. Bird species include western meadowlark, turkey vulture, and American kestrel.

10.1.2.9.3 Special-Status Species

Grassland special-status species include greater western mastiff bat, Merced kangaroo rat, Nelson's antelope ground squirrel, grasshopper sparrow, greater sandhill crane, long-billed curlew, mountain plover, northern harrier, short-eared owl, Swainson's hawk, tricolored black bird, western burrowing owl, white-tailed kite, California horned lark, prairie falcon, San Joaquin whipsnake, California red-legged frog, California tiger salamander, western spadefoot toad, Callippe silverspot, and valley elderberry longhorn beetle.

Grassland special-status plant species include Henderson's bentgrass, Clara Hunt's milk vetch, Jepson's milk-vetch, Ferris' milk-vetch, alkali milk-vetch, heartscale, brittlescale, San Joaquin spearscale, lesser saltscale, Indian Valley brodiaea, beakerd clarkia, silky cryptantha, recurved larkspur, diamond-petaled California poppy, adobe lily, Congdon's tarplant, Brewer's western flax, drymaria-like western flax, red-flowered lotus, Ahart's paronychia, Merced phacelia, Hartweg's golden sunburst, California beaked rush, and Sanford's arrowhead.

10.1.2.10 Upland Scrub

Upland scrub habitat includes habitat areas dominated by shrubs characteristic of coastal scrub, chaparral, and saltbush scrub communities.

Sacramento River
Upland scrub habitat can be found around Lake Shasta and Keswick Reservoir.

Feather River
Mixed chapparal occurs on steep south-facing slopes particularly at Lake Oroville.

Yuba River
Upland scrub habitats surround portions of New Bullards Bar Reservoir.

American River
Upland scrub habitats occur along portions of the Middle and Lower North Forks of the American River and around Folsom Lake.

Merced/San Joaquin River
Upland scrub habitats occur around portions of Lakes McClure and McSwain.

10.1.2.10.1 Vegetation

Upland scrub habitat is dominated by several types of vegetation including, ceanothus, manzanita, bitter cherry, oaks, poison oak, coffee berry, buckbrush, California buckeye, toyon, sugar sumac, chamise, saltbush, sagebrush, and creosote bush.

10.1.2.10.2 Wildlife

Upland scrub habitats support brush rabbit, black-tailed jackrabbit, mule deer, and birds such as rufous-sided towhee, California quail, California thrasher, and red-tailed hawk.

10.1.2.10.3 Special-Status Species

Upland scrub special-status species include greater western mastiff bat, ringtail, golden eagle, Swainson's hawk, prairie falcon, Cooper's hawk, San Joaquin whipsnake, and foothill yellow-legged frog.

Upland scrub special-status plant species include dimorphic snapdragon, Indian Valley brodiaea, dwarf soaproot, Mariposa clarkia, Baker's larkspur, Brandegee's eriastrum, adobe lily, El Dorado bedstraw, Brewer's western flax, drymaria-like western flax, Napa western flax, Tehama county western flax, Parry's horkelia, saw-toothed lewisia, Hall's bush mallow, Mount Diablo phacelia, and Arburua Ranch jewelflower.

10.1.2.11 Valley/Foothill Woodland and Forest

Valley/foothill woodland and forest (VWF) habitat includes nonriparian forest, woodland, and savanna of valleys and foothills.

Sacramento River

VWF habitats are scattered along the Sacramento River often adjacent to VFR habitats. Also, the Woodson Bridge State Recreation Area includes an oak woodland park.

Feather River

Isolated patches of blue oak woodland habitat occur at lower elevations bordering Lake Oroville on south facing slopes. Interior live oak woodlands occur at Lake Oroville on all aspects at elevations below 1,000 feet, and on south-facing slopes at elevations above 1,000 feet. Canyon live oaks occur in protected areas including north-facing slopes, canyons, and along drainages. Extensive mixed oak woodlands occur at elevation above 1,000 feet surrounding Lake Oroville. At elevations below 1,000 feet mixed oak woodlands occur on north and east facing slopes. The Oroville and Feather River Wildlife Areas also support VWF habitat.

Yuba River

VWF habitats are scattered along the Yuba River from Timbuctoo Bend to the Yuba River's juncture with the Feather River.

American River
VWF habitat is scattered along lower portions of American River and along portions of the Folsom Lake shoreline.

Merced/San Joaquin River
VWF habitats occur around portions of Lakes McClure and McSwain.

10.1.2.11.1 Vegetation
Valley/Foothill woodland and forest habitat is often dominated by sycamore, black walnut, foothill pine, valley oak, live oak, juniper, blue oak, interior live oak, coast live oak, and California buckeye.

10.1.2.11.2 Wildlife
VFW habitat supports a variety of wildlife, including: acorn woodpecker, northern flicker, wild turkey, plain titmouse, black-tailed jackrabbit, American crow, California quail, Bewick's wren, western fence lizard, coyote, mule deer, California ground squirrel, western gray squirrel, scrub jay, beaver, river otter, muskrat, skunk, raccoon, wood ducks, pheasant, Nutall's woodpecker, western wood pewee, hermit thrush, yellow-billed magpies, gopher snake, common kingsnake, and western rattlesnake.

10.1.2.11.3 Special-Status Species
VWF special-status species include greater western mastiff bat, ringtail, Cooper's hawk, long-eared owl, osprey, Swainson's hawk, bald eagle, white-tailed kite, golden eagle, and northern goshawk.

VWF special-status plant species include dimorphic snapdragon, Clara Hunt's milk-vetch, Jepson's milk-vetch, Mariposa clarkia, Shasta clarkia, beaked clarkia, silky cryptantha, recurved larkspur, Brandegee's eriastrum, adobe lily, El Dorado bedstraw, Congdon's tarplant, Brewer's western flax, drymaria-like western flax, Napa western flax, Tehama County western flax, Parry's horkelia, Mt. Tedoc linanthus, Madera linanthus, red-flowered lotus, Ahart's paronychia, thread-leaved beardtongue, Mt. Diablo phacelia, and Hartweg's golden sunburst.

10.1.2.12 Montane Woodland and Forest
Montane woodland and forest (MWF) habitat includes nonriparian forest and woodland above the foothills.

Sacramento River
MWF can be found around portions of Lake Shasta and Keswick Reservoir.

Feather River
MWF can be found around portions of Little Grass Valley and Sly Creek Reservoirs and Lake Oroville.

Yuba River
MWF can be found around portions of New Bullard's Bar Reservoir.

American River
MWF can be found around portions of French Meadows and Hell Hole Reservoirs and the northern shores of Folsom Lake.

10.1.2.12.1 Vegetation
Montane woodland and forest vegetation is dominated by white fir, Douglas fir, ponderosa pine, Jeffery pine, red fir, lodgepole pine, sugar pine, live oak, tanoak, incense cedar, coulter pine, willows, alders, black cottonwood, aspens, black oak, and knobcone pine.

10.1.2.12.2 Wildlife
Wildlife associated with MWF includes: western tanager, white-breasted nuthatch, woodpeckers, mule deer, bobcat, mountain lion, raccoon, striped skunk, black bear, beaver, marmot, chipmunk, coyote, fisher, pine martin, and weasel.

10.1.2.12.3 Special-Status Species
MWF special-status animal species include California wolverine, greater western mastiff bat, ringtail, bald eagle, Cooper's hawk, northern spotted owl, and osprey.

Special-status plant species include Indian Valley brodiaea, silky cryptantha, drymaria-like western flax, saw-toothed lewisia, Mount Tedoc linanthus, Madera linanthus, thread leaved beardtongue, California beaked-rush, and marsh skullcap.

10.1.2.13 Upland Cropland
Upland cropland habitat includes agricultural lands farmed for grain field, truck, and other crops for profit that are not seasonally flooded.

Upland cropland areas are found throughout the Sacramento Valley. However, EWA water acquisition actions will only involve cotton fields in the San Joaquin Valley.

10.1.2.13.1 Vegetation
Upland cropland vegetation is dominated by cereal rye, barley, wheat, corn, dry beans, safflower, alfalfa, cotton, tomatoes, lettuce, Bermuda grass, ryegrass, tall fescue, almonds, walnuts, peaches, plums, and grapes.

10.1.2.13.2 Wildlife
Wildlife use of these areas varies throughout the growing season with crop type, level of disturbance, and available cover. Orchard and vineyard typically support resident species, such as scrub jay, northern mockingbird, yellow-billed magpie, American crow, and northern flicker. During the winter, orchard habitats provide foraging habitat and roosting sites for many songbirds species including the white-crowned sparrow, dark-eyed junco, golden-crowned sparrow, lesser goldfinch, and yellow-rumped warbler. Species associated with field and row crops include the red-winged blackbird, European starling, western meadowlark, California vole, black-tailed jackrabbit, western harvest mouse, Botta's pocket gopher, raccoon, striped skunk, and Virginia opossum. Croplands provide foraging habitat for many raptors including the northern harrier, red-tailed hawk, and white-tailed kite.

10.1.2.13.3 Special-Status Species

Upland cropland special-status species includes San Joaquin kit fox, Aleutian Canada goose, California gull, greater sandhill crane, long-billed curlew, mountain plover, northern harrier, Swainson's hawk, tricolored blackbird, western burrowing owl, white-faced ibis, and white-tailed kite.

10.1.2.14 Seasonally Flooded Agriculture

Seasonally flooded agricultural land habitat includes agricultural lands farmed for grain, rice, field, truck, and other crops for profit that require seasonal flooding for at least one week at a time as a management practice (e.g., for pest control and irrigation) or are purposely flooded seasonally to enhance habitat values for specific wildlife species (e.g., ducks for duck clubs). Agricultural ditches and drains associated with maintaining seasonally flooded agricultural land are included in this habitat type.

Seasonally flooded agriculture is found throughout the Sacramento Valley. However, currently the EWA agencies are only considering idling up to 89,608 acres of rice crop in six counties (Glenn, Colusa, Butte, Sutter, Placer, and Yolo). These counties typically harvest about 496,820 acres of rice (USDA 2002). For more information on crop idling within these counties refer to Section 2.4.2.1.3.

10.1.2.14.1 Vegetation

For the purposes of the EWA program, EWA actions affecting seasonally flooded agriculture will be focused on rice fields.

10.1.2.14.2 Wildlife

- Rice fields provide important foraging habitat for a variety of wildlife species. (See examples in Table 10-3 and Figure 10-3.) Many species forage on post-harvest waste grain (on average 300-350 pounds per acre depending upon harvest method) and other food found within the fields (more than 250 pounds per acre), such as duckweed, fish, and crayfish and other invertebrates (Brouder and Hill 1995). Typically various birds and rodents consume rice waste grain and then raptors feed on the birds and rodents. Duckweed and other moist soil plants can provide high quality food for waterfowl. Water level manipulations are necessary for moist soil plant germination and maturity. Fish are often entrained in the irrigation canals that supply water to the rice fields. Crayfish are found in the canal banks and berms of the rice fields. Simply continuing to pump water through the canals will ensure some level of fish and crayfish abundance for wildlife such as herons, cranes, egrets, etc.

Figure 10-3
Great Blue Heron Using Flooded Rice Field

Opossum	*Didelphis virginiana*	-
River Otter	*Lutra canadensis*	-
Beaver	*Castor canadensis*	-
Muskrat	*Ondatra zibethicus*	-

[1]RMI 1997 and CALFED 1998.
[2] Status Codes
FE = Listed as Endangered under ESA
FT = Listed as Threatened under ESA
PT = Proposed for listing as Threatened under ESA
FSC = Federal species of management concern
PR = Protected under the Bald and Golden Eagle Protection Act
SE = Listed as Endangered under CESA
ST = Listed as Threatened under CESA
FP = Fully protected under California Fish and Game Code
CSC = California Department of Fish and Game "species of special concern"
* = Species breeds or in some manner uses rice cultural habitats for successful reproduction.

Other invertebrates and their larvae can be found in very shallow water particularly during an early to midseason drawdown. These invertebrates, such as bloodworms, are particularly important to shorebirds.

Rice also provides resting, nesting, and breeding habitat similar to natural wetlands. Irrigation ditches can contain wetland vegetation such as cattails, which provide cover habitat for rails, egrets, herons, bitterns, marsh wrens, sparrows, and common yellowthroats. Rice fields provide pair, brood, and nesting habitat for species such as the mallard, northern pintail, and black tern. Both the Waterfowl and Special-Status Species section below provide more information on the association between rice and these wildlife categories.

Waterfowl

Although the extent of wetlands that once existed isn't precisely known, it is estimated that within the last 100 years, 95 percent of the Central Valley wetlands have been converted to cropland or other anthropogenic uses. Of the remaining 383,000 acres of wetlands left in the Central Valley, 2/3 are privately owned; the remaining 1/3 is divided between state wildlife management areas and federal National Wildlife Refuges (Harrell et. al. 1995). Because of the loss of wetland habitat, wintering waterfowl populations have been reduced to between three and five million (RMI 1997). With the continued loss of wetlands, waterfowl within the Sacramento Valley have become increasingly dependent upon managed seasonally flooded wetlands and agricultural lands, including rice fields, for food and cover. Despite the reduced waterfowl numbers, the Central Valley supports 250 species of birds that includes 60 percent of all wintering waterfowl on the Pacific Flyway. Waterfowl supported by the Central Valley fall into four groups:

- **Permanent residents** – These are primarily breeding ducks, such as mallard ducks, cinnamon teal, gadwell and wood ducks. For successful breeding, "pair",

upland nesting areas, and "brood water" habitats are needed. "Pair" water consists of shallow water (4-12 inches deep) in wetlands, ditches, or small ponds that are adjacent to upland nesting fields. These areas have good invertebrate populations that are believed to be the primary food source of pre-laying hens. Breeding ducks begin establishing territories and accumulating fat and protein reserves between February and May prior to nesting (Smith 1995). Nesting occurs in adjacent uplands. Once the young have fledged, "brood water" is needed to support the hen and ducklings. Spring and summer wetlands can serve as suitable brood water providing these wetlands have a sufficient quantity of invertebrate foods, contain vegetative cover for protection from predators, and are located near upland nesting sites. Spring/summer wetlands that are flooded for part of the year (such as rice fields/duck hunting sites) can provide good duck brood habitat. Wild rice, which is typically planted and flooded in late March, may be especially important as early brood habitat.

- **Winter residents** – These include the greater and lesser sandhill crane (often included with waterfowl because of their closely associated life history requirements), white geese (snow and Ross'), cackling Canada geese, and various species of ducks. Of the wintering ducks, the northern pintail is the most abundant with a winter population of approximately 1.6 million birds. The mallard duck is the next most abundant. Other ducks include the American widgeon, northern shoveler, green-winged teal, gadwell, cinnamon teal, ruddy duck, and canvasback ducks. Winter residents migrate to the Central Valley during the fall (September – November) and depart in spring (March – May) for their summer breeding grounds. Wintering waterfowl tend to use shallow marshes, agricultural fields such as rice, some uplands, and open lakes.

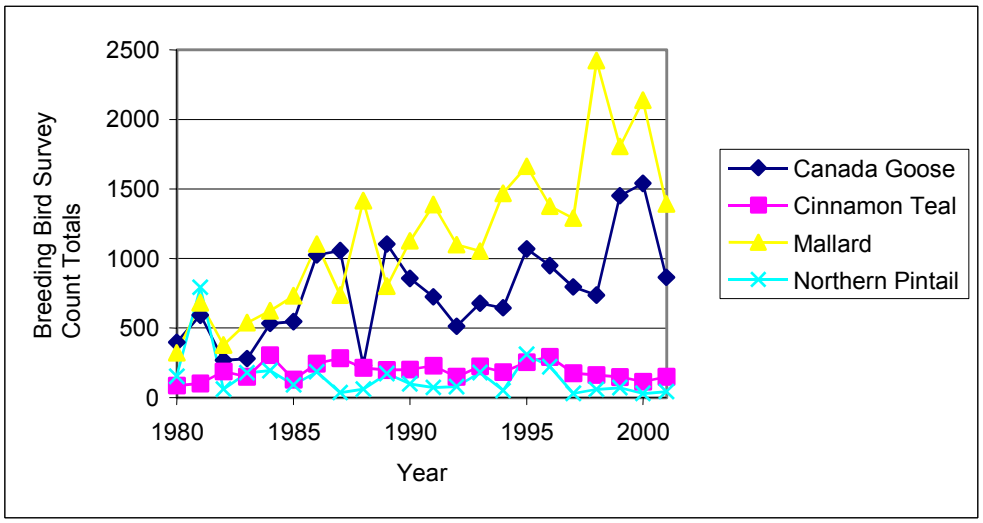
- **Summer Residents** – The cinnamon teal is an example of a summer resident duck of the Central Valley. It begins to arrive in the Central Valley in mid-February to establish territories. Other marsh dwellers begin to arrive in mid-March with yet another wave of species arriving in late May. Summer residents depart the Valley for their wintering grounds in the fall (Engilis 1995).

- **Transient Residents** – Transients residents pass through the Central Valley in March through May and/or August through October while en route to their winter or summer grounds.

To guide management and conservation efforts, research has been conducted to determine habitat usage and foraging behavior by wintering waterfowl. The results of these studies indicate that within the Sacramento Valley, waterfowl used flooded rice fields differently than semi-natural wetlands for both foraging and cover (Elphick et. al. 1996). Birds tended to use dry fields in the early fall when flooded fields were not available and in late winter (February) in the absence of rain-filled fields. (Miller and Newton 1999) Some habitats are used at night to provide food for certain species (such as the green winged teal) but these same habitats only provide thermal cover or protection from nocturnal predators for others (wood ducks, mallards). All studies

indicate that diverse habitats are required/optimal to provide needed uses of all wintering species.

Migrating waterfowl that begin arriving in August depend on food from both the managed wetlands and flooded rice fields. The elimination of historic wetlands within the Sacramento Valley has resulted in rice seed becoming an increasingly essential food in the diet of migrating waterfowl residents. Rice is a particularly important food for green-winged teal, pintail, widgeon and mallard-ducks; white-fronted, Canada, snow and Ross' geese. Critical periods of energy expenditure for individual wintering pintails within the Sacramento Valley determined for a dry and wet year were found to include the early fall period from August through November when rapidly increasing daily energy was required from food (DER_{food}); a period of lowered DER_{food} and increased daily energy required from body reserves ($DER_{reserves}$) during late winter (January and February when food availability is diminished); and a period when daily energy expenditure (DEE) and DER_{food} decreased somewhat during February and March of the wet year (Miller and Newton 1999). In the dry year monitored, $DER_{reserves}$ increased in February and March. The greatest population demand for food occurred in December and January when pintails were most abundant and body mass was low or moderate.



Types of foods that were consumed during these critical periods were investigated in other studies of fall and winter foods consumed by northern pintails overwintering in the Sacramento Valley (Miller 1987 and Miller and Newton 1999). In addition to rice seed from unharvested refuge wetlands, seeds available included swamp timothy, barnyard grass, flat sedges, and smartweeds. Marsh seeds were used intensively in the fall, but rice seed was still a dominant factor in pintail foraging routines. Rice, although high in carbohydrates, lacks essential nutrients that include the proper complements of amino acids, fatty acids, minerals and vitamins in natural marsh seeds that are crucial to survival and reproduction of waterfowl. However, rice fields serve as a supplement when marsh seeds are not available.

After arriving in the Sacramento valley, waterfowl feed exclusively on vegetation. As the winter progresses, vegetation intake was found to decrease while invertebrate intake increased in mid-winter and reached as high as 65 to 70 percent of daily intake in late winter. Flooded-harvested rice fields on the wildlife refuges were excellent sources of midge larvae in late winter. Ponds on private lands, however, are normally drained in mid-January following the last day of hunting season, which eliminates roosting space and productive invertebrate feeding areas. Midges, for example, die within 10 days of drainage. The invertebrates provide dietary protein that may be required several weeks prior to rapid growth of reproductive organs, and therefore late winter consumption of invertebrates may directly affect reproductive performance. Protein is also needed for the mid-winter molt and egg laying process. Pintails were found to roost on flooded rice fields more frequently as the winter progressed where they increasingly relied on night feeding of rice seeds and invertebrates.

Relatively recent methods of straw management have begun to affect the food available to wintering waterfowl on rice fields. These methods, that include flooding and wet rolling, straw chopping and incorporation through discing or other means, and straw removal, have replaced burning as the primary means of straw disposal. This change was brought about as a result of the Rice Straw Burning Reduction Act (AB 1378) passed by the California legislature in 1991 that restricted burning due to concerns over air quality in Northern California (Brouder and Hill 1995). Straw removal/disposal off-site, which is not economical due to poorly developed market options), and traditional straw cutting and discing drastically decreases the amount of residual rice seed and optimal habitat available to waterfowl. Shallow flooding and wet rolling, however, which results in waste rice seed floating on shallow floodwaters, preserves residual rice seed as a carbohydrate source and creates winter habitat that fosters growth of important invertebrate species needed for reproductive success (Brouder and Hill 1995).

Research has shown that after harvest, and before burning (the method traditionally used to dispose of rice straw residue), there was an average of 260 pounds of rice per acre lay on the ground an additional 86 pounds per acre on the straw stubble (Brouder and Hill 1995). These figures were generated from fields on which the rice was harvesting using conventional cutter-bar technology common in the 1980's, which cuts the rice stalks and leaves the stubble. In the 1990's with the advent of stripper headers, which strips seeds off of the seed heads but leaves the rice stalk standing, an average of 260 pounds of rice per acre lay directly on the ground, but only 46 pounds of rice per acre remained on the straw. In addition, rice fields provide approximately 250 pounds per acre of naturally occurring food sources such as small invertebrates, tubers, edible shoots, and seeds. From these figures, it appears that rice fields managed as wetlands can provide almost 600 pounds per acre, which is approximately 80 percent of the food found in natural wetlands (Brouder and Hill 1995).

As stated above, the abundance of waterfowl in the Central Valley has greatly declined from historic numbers. Since the late 1870's, waterfowl wintering in the Central Valley has declined dramatically, due to a variety of reasons that include extended periods of drought on northern breeding grounds and associated decline in suitable nesting habitat, and loss of wetlands in the Central Valley wintering grounds. Concern over loss of wetland habitat peaked when, in 1981, the relationship between winter habitat quantity and quality and hunter success was demonstrated. The discovery of large successful nesting populations in the Central Valley and recognition that duck hunting was better on well managed wetlands than flooded rice fields increased interest in private wetland management in the 1980's. Through efforts of waterfowl conservation groups, proactive management of both breeding and winter waterfowl habitats by the US and Canadian governments, California waterfowl population began to change so that by the early 1990's, numbers began increasing for many species (RMI 1997). (See Figure 10-4.)

Source: Sauer, J. R., et. al..

Figure 10-4
Breeding Bird Survey Results 1980-2001

The USFWS report on trends in duck breeding populations within the traditional survey area (primarily western and central U.S. and Canada) over the period from 1955 through 2001 indicates that the 2001 population estimates for ducks, blue winged teal, gadwalls, green winged teal, and northern shovelers all exceed historical average population figures. Mallards, widgeons, redheads and canvasbacks 2001 populations are approximately equal to historical averages. Pintail and scaup numbers, however, are below historic average population figures (Wilkins et. al. 2001). The pintail population, which has steadily fallen beginning in 1970 (6.4 million), began to increase by the mid-1990's, but the 2001 estimate of 3.3 million is still significantly less than the early 1970 averages (RMI 1997).

10.1.2.14.3 Special-Status Species

Certain special-status species rely on, to varying degrees, seasonally flooded agricultural lands, in particular rice fields and their associated uplands, drainage ditches, irrigation canals, and dikes. Detailed species accounts for species of concern to EWA agencies can be found in Appendix J, the EWA ASIP. The relationship between these species and rice production in the Sacramento Valley is described in Table 10-7, Section 10.2.6.1.7. Figure 10-5 provides a brief overview of the rice production cycle.

10.1.3 Delta Region

The Delta Region encompasses the legal limits of the Delta as described in California Water Code Section 12220. Figure 3-3 in Chapter 3 shows the Delta Region and its facilities. Each NCCP Community was described at a general level of detail in the Upstream from the Delta Region. This section will detail the existing conditions as they apply to the EWA area of analysis within the Delta Region. Some habitats occur in the Upstream from the Delta Region and in the Delta Region. Habitat descriptions for those habitats can be found in Section 10.1.2, Upstream from the Delta Region. The Delta Region sections for these habitats will simply include the habitat location and associated wildlife and special-status species.

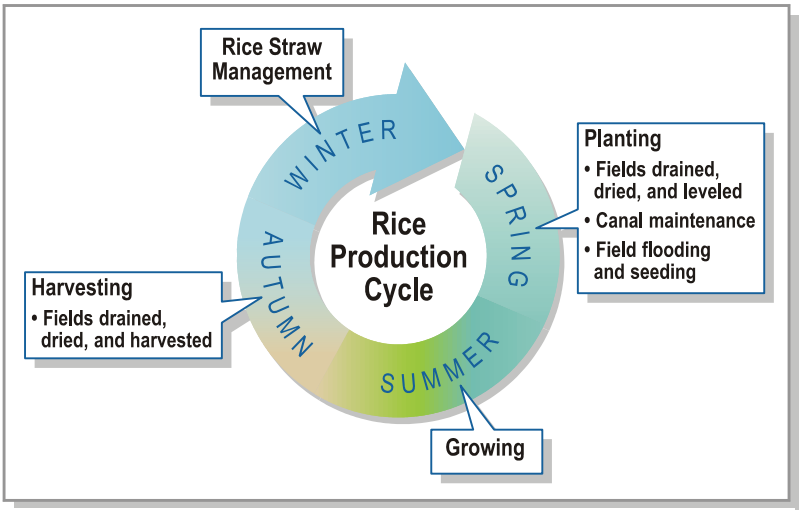


Figure 10-5
Rice Production Cycle

The Sacramento, San Joaquin, and other rivers, join in the Delta and flow westward into Suisun and San Pablo bays, and ultimately, reach the San Francisco Bay. Today, the Delta Region contains about 641,000 acres of agricultural land (72 percent of the total land area) that dominate its lowland areas. Other dominant habitats in the region include valley foothill riparian and fresh and saline emergent wetlands. Although less prominent, other important habitats include seasonal fresh-water wetlands and nontidal freshwater, tidal freshwater, and brackish water emergent marsh. Hundreds of miles of waterways divide the Delta Region into islands, some of which are below sea level. The Delta Region relies on more than 1,000 miles of levees to protect these islands. Suisun marsh represents over ten percent of the remaining wetlands in California and is one of the largest contiguous marshlands in the U.S. (Entrix 1996).

10.1.3.1 Tidal Perennial Aquatic

Tidal perennial aquatic (TPA) habitat is defined as deepwater aquatic (greater than 3 meters deep from mean low lowtide), shallow aquatic (less than or equal to 3 meters deep from mean low lowtide), and unvegetated intertidal (tideflats) zones of estuarine bays, river channels, and sloughs.

Tidal perennial aquatic habitat within the Delta occurs in open water including sloughs and channels in the Delta, and bays. Deep open-water areas are largely unvegetated; beds of aquatic plants occasionally occur in shallower open-water areas.

10.1.3.1.1 Vegetation

TPA habitats are largely unvegetated.

10.1.3.1.2 Wildlife

Tidal perennial aquatic habitat is used as foraging and resting habitat and escape cover for shorebirds, wading birds, and waterfowl. Double-crested cormorant, California gull, ring-billed gull, herring gull, migrating waterfowl such as canvasback, red head, ring-necked duck, greater scaup, lesser scaup, common golden eye, and bufflehead.

10.1.3.1.3 Special-Status Species

Special-status wildlife species associated with TPA habitat include: Aleutian Canada goose, American peregrine falcon, bald eagle, California brown pelican, western snowy plover, California least tern, California gull, long-billed curlew, and osprey.

10.1.3.2 Valley Riverine Aquatic

Delta VRA habitat includes the Sacramento, San Joaquin, Consumnes, Mokelumne, and Calaveras rivers; and sloughs, streams, and ephemeral creeks. Major waterways in Suisun Bay and Marsh area include Suisun, Montezuma, and Nurse sloughs. River channels and sloughs associated with the Sacramento and San Joaquin Rivers.

10.1.3.2.1 Wildlife

Many species rely on riverine habitat and the associated adjacent habitats. Bird species, including herons, shorebirds, and songbirds commonly forage in this habitat. Amphibians, such as newts and frogs are closely associated with the riverine environment. Also, several mammal species are linked to river habitats including the river otter, mink, muskrat, and beaver.

10.1.3.2.2 Special-Status Species

Special-status species associated with VRA include bald eagle, bank swallow, osprey, western pond turtle, California red-legged frog, foothill yellow-legged frog, and eel-grass pondweed.

10.1.3.3 Lacustrine

Lacustrine habitats such as dead end sloughs, forebays, and flooded islands can be found throughout the Delta.

10.1.3.3.1 Wildlife

This habitat provides foraging habitat for a variety of wildlife species including fish-eating birds such as terns, grebes, cormorants, herons, and waterfowl. In addition, it provides habitat for beaver, river otter, and muskrat.

10.1.3.3.2 Special-Status Species

Special-status species associated with lacustrine habitats include bald eagle, Aleutian Canada goose, California gull, osprey, western pond turtle, California red-legged frog, California tiger salamander, and eel-grass pondweed.

10.1.3.4 Saline Emergent

Saline emergent habitat includes the portions of San Francisco, San Pablo, and Suisun Bays and the Delta that support emergent wetland plant species that are tolerant of saline or brackish conditions within the intertidal zone or on lands that historically were subject to tidal exchange (diked wetlands).

The dominant vegetation for saline emergent habitats includes cordgrass, pickleweed, bulrush, glasswort, saltwort, saltgrass, arrowgrass, seablite, hairgrass, cattail, common reed, and algae.

10.1.3.4.1 Wildlife

More than 25 species of birds and mammals used saline emergent wetlands (CALFED 2000a). Examples include herons, egrets, ducks, hawks, and a variety of rodents.

10.1.3.4.2 Special-Status Species

Special-status animal species associated with saline emergent habitats includes salt marsh harvest mouse, San Pablo California vole, Suisun ornate shrew, Aleutian Canada goose, American peregrine falcon, California black rail, California clapper rail, California gull, long-billed curlew, northern harrier, saltmarsh common yellowthroat, San Pablo song sparrow, short-eared owl, Suisun song sparrow, white-tailed kite, Suisun marsh aster, Suisun thistle, soft bird's beak, Delta tule pea, Marin knotweed, and California seablite. Other species include saltmarsh wandering shrew, California least tern, black-crowned night heron, great blue heron, snowy egret, great egret, and marsh wren.

Special-status plant species include Ferris' milkvetch, palmate-bracted bird's beak, narrow-leaf gumplant, heartscale, San Joaquin spearscale, crownscale, brittlescale, Delta button celery, hairy bird's beak, Mason's lilaeopsis, bristly sedge, rose-mallow, mad-dog skullcap, Delta mudwort, and Delta coyote-thistle.

10.1.3.5 Tidal Freshwater Emergent

Tidal freshwater emergent habitat includes portions of the intertidal zones of the Delta that support emergent wetland plant species that are not tolerant of saline or brackish conditions.

Tidal fresh-water and brackish-water emergent marsh habitat occurs on in-stream islands and along mostly unleveed, tidally influenced waterways. Tidal emergent marsh provides habitat for many special-status species. The Suisun Marsh is the largest contiguous brackish water wetland in California (USFWS 2000).

The dominant vegetation for tidal freshwater emergent habitat includes California, river, and big bulrush, tules, cattails, and common reed.

10.1.3.5.1 Wildlife

Freshwater emergent wetlands are among the most productive wildlife habitats in California. They provide food, cover, and water for more than 160 species of birds and numerous mammals, reptiles, and amphibians (Kramer 2003). The Suisun Marsh is a critical resource for wintering waterfowl providing resting, and feeding habitat for up to 28 percent of the waterfowl along the Pacific Flyway during the autumn in low rainfall years (Entrix 1996). Approximately 200 species of birds, 45 species of mammals, and 36 species of amphibians and reptiles inhabit the Suisun Marsh environs (USFWS 2000). Over 50 species of birds, mammals, reptiles, and amphibians use freshwater emergent wetlands in the Delta (CALFED 2000a).

10.1.3.5.2 Special-Status Species

Special-status animal species includes: Suisun ornate shrew, salt marsh common yellowthroat, giant garter snake, Aleutian Canada goose, bald eagle, peregrine falcon, black tern, black rail, California clapper rail, California gull, long-billed curlew, northern harrier, short-eared owl, Suisun song sparrow, white-faced ibis, and white-tailed kite.

Special-status plant species of Suisun Bay include Suisun Marsh aster, Antioch Dunes evening primrose, Carquinez golden bush, Contra Costa goldfields, Delta tule pea, Delta mudwort, brittlescale, Valley spearscale, Suisun thistle, soft bird's-beak, Contra Costa wallflower, Mason's lilaeopsis, California hibiscus, bristly sedge, Jepson's Tule Pea, marsh mudwort, Sanford's arrowhead, marsh scallup, rose-mallow, mad-dog skullcap, Delta coyote-thistle, Point Reyes bird's-beak.

10.1.3.6 Nontidal Freshwater Permanent Emergent

Nontidal freshwater permanent emergent habitat occurs on the landward side of Delta Region levees and in the interiors of Delta Region islands, mostly in constructed waterways and ponds in agricultural areas. Occur throughout the Delta in areas where soils are inundated or saturated for all or most of the growing season, primarily around Delta islands, backwater areas, and in thin bands along Delta rivers and channels where accumulation of sediments has occurred. This habitat also occurs on Delta islands in low-lying areas among crop and pasture land.

10.1.3.6.1 Wildlife

These areas are extremely productive and important habitat for hundreds of different species of birds, mammals, reptiles, and amphibians. Many species entire life cycles rely on this habitat while migratory species, such as ducks and geese, use these wetlands seasonally. Over 50 species of birds, mammals, reptiles, and amphibians use freshwater emergent wetlands in the Delta (CALFED 2000a).

10.1.3.6.2 Special-Status Species

Special-status animal species include: California black rail, giant garter snake, western pond turtle, and greater sandhill crane.

Special-status plant species are similar to those listed above for tidal freshwater permanent emergent habitat.

10.1.3.7 Natural Seasonal Wetland

Seasonal freshwater wetlands include inland freshwater marshes, which maintain surface water during only a portion of the year and vernal pools, which are associated with grasslands.

10.1.3.7.1 Wildlife

The wetlands of the Delta provide habitat for a number of shorebirds and waterfowl species including killdeer, western sandpiper, greater yellow-legs, American coot, American widgeon, gadwall, mallard, canvasback, and common moorhen. Waterfowl and shorebirds prey extensively on invertebrates and forage primarily in permanent saline, brackish, and fresh-water marshes, seasonal wetlands, and agricultural cropland. These areas also support a number of mammals such as coyote, gray fox, muskrat, river otter, and beaver. Several species of reptiles and amphibians also occur in this region.

10.1.3.7.2 Special-Status Species

Special-status species associated with NSW include American peregrine falcon, California gull, greater sandhill crane, long-billed curlew, northern harrier, short-eared owl, Swainson's hawk, tricolored blackbird, white-tailed kite, giant garter snake, California red-legged frog, California tiger salamander, western spadefoot toad, conservancy fairy shrimp, Delta green ground beetle, longhorn fairy shrimp, mid-valley fairy shrimp, vernal pool fairy shrimp, and vernal pool tadpole shrimp.

Special-status plant species associated with NSW include Alkali milk-vetch, Crampton's tuctoria, Colusa grass, Bogg's lake hedge-hyssop, legenere, Hoover's spurge, Butte County meadowfoam, Greene's tuctoria, slender orcutt grass, hairy orcutt grass.

10.1.3.8 Managed Seasonal Wetland

Large seasonal wetlands managed for waterfowl are in the northwestern part of the Delta Region, west of the Sacramento Deep Water Ship Channel. These managed seasonal wetlands are of great importance to migratory waterfowl and shorebird populations for the forage that these wetlands provide during fall, winter, and spring, when bird populations in the Delta increase dramatically.

A significant managed private wetland in the Central Delta is a 395-acre State easement project on Empire Tract west of Lodi (USFWS 2000). According to the Central Valley Wetlands Supply Investigation (USFWS 2000) the Delta Basin (defined to include all land between the American River and the Stanislaus River, the Sierra Nevada foothills and the Sacramento River/Deepwater ship channel and Coast Range to the west) contains 32,210 acres of privately managed wetlands, 92 percent of which occurs in the Suisun Bay area. The water supply for these privately managed wetlands comes primarily from landowners' riparian or appropriative rights and the distribution by diversion from Delta channels and tributaries directly onto properties.

10.1.3.8.1 Wildlife

MSW habitats are often managed for waterfowl such as mallards, pintails, American widgeon, and Canada and other geese. MSW habitats also support a variety of wading and shorebirds, such as herons, egrets, terns, and gulls.

10.1.3.8.2 Special-Status Species

Special-status animal species associated with MSW include saltmarsh harvest mouse, San Pablo California vole, Suisun ornate shrew, Aleutian Canada goose, American peregrine falcon, bald eagle, black tern, California gull, greater sandhill crane, long-billed curlew, northern harrier, San Pablo song sparrow, short-eared owl, Suisun song sparrow, Swainson's hawk, tricolored blackbird, western snowy plover, white-faced ibis, white-tailed kite, giant garter snake, western pond turtle, California red-legged frog, and vernal pool tadpole shrimp.

Special-status plant species associated with MSW are similar to those listed above for natural seasonal wetlands habitats.

10.1.3.9 Valley/Foothill Riparian

Riparian scrub typically occurs on channel islands or levees and along unmaintained, narrow channel banks of Delta Region creeks, waterways, and major tributaries. The major rivers of the Delta Region include the Sacramento, San Joaquin, Mokelumne, Cosumnes, and Calaveras. About 7,000 acres of riparian vegetation occur primarily on the levees of Delta islands and along the Cosumnes and Mokelumne Rivers. The riparian zone along leveed islands is usually very narrow, but more extensive riparian areas occur along the San Joaquin River just below its confluence with the Stanislaus River and along the Cosumnes River. Scattered throughout the Delta System on islands, along levees, in backwater areas, in sloughs, and in thin bands along river channels.

10.1.3.9.1 Wildlife

VFR habitats provide refuge shelter food water resting and nesting sites for at least 50 amphibian and reptile species, 147 birds, and 55 mammals (Entrix 1996). A number of these species are listed in Section 10.1.2.7.

10.1.3.9.2 Special-Status Species

Special-status animal species associated with VFR habitat include greater western mastiff bat, ringtail, riparian brush rabbit, San Joaquin Valley woodrat, western yellow-billed cuckoo, bank swallow, bald eagle, black-crowned night heron, California yellow warbler, Cooper's hawk, double-crested cormorant, golden eagle, great blue heron, great egret, least bell's vireo, little willow flycatcher, long-eared owl, osprey, snowy egret, Swainson's hawk, white-tailed kite, yellow-breasted chat, giant garter snake, western pond turtle, California red-legged frog, foothill yellow-legged frog, and valley elderberry longhorn beetle.

Special-status plant species associated with VFR include slough thistle, silky cryptantha, Delta coyote-thistle, marsh checkerbloom, fox sedge, rose-mallow, northern California black walnut, and Sanford's arrowhead.

10.1.3.10 Grassland

Grasslands occur in many outlying areas surrounding the Delta and on islands in the Delta.

10.1.3.10.1 Wildlife

Grassland provides foraging and denning habitat for several mammal species such as the California ground squirrel, badger, skunk, and coyote. Other common species found in this habitat include the ring-necked pheasant, western meadowlark, red-tailed hawk, western toad, and gopher snake.

10.1.3.10.2 Special-Status Species

Grassland special-status species includes many of those listed in Sections 10.1.2.9 and 10.1.4.4.

10.1.3.11 Inland Dune Scrub

Inland dune scrub (IDS) habitat comprises vegetated stabilized sand dunes associated with river and estuarine systems. This habitat can be found at the Antioch Dunes National Wildlife Refuge (ADNWR) and Brannan Island State Park. IDS habitat also historically occurred in the Antioch-Oakley areas, Delta marshes, and as small isolated dunes on eastern edge Delta.

10.1.3.11.1 Vegetation

Dominant vegetation is comprised of primarily special-status species, but also includes primrose, wallflower, buckwheat, elegant clarkia, California poppy, California croton, Grindelia, deerweed, telegraph weed, California matchweed, and silver bush lupine.

10.1.3.11.2 Wildlife

Wildlife associated with IDS habitat include mink, desert cottontail rabbit, beaver, muskrat, opossum, weasel, skunk, gopher, gray fox, Beechy ground squirrel, coyote, blacktail jack rabbit, raccoon, Townsend's mole, weasel, red fox, California legless lizard, sideblotched lizard, coast horned lizard, San Joaquin whipsnake, glossy snake, western whiptail lizard and the fence lizard.

10.1.3.11.3 Special-Status Species

IDS special-status species include San Joaquin whipsnake, Lange's metalmark butterfly, Antioch dunes evening primrose, Contra Costa wallflower, and Delta green ground beetle.

10.1.3.12 Upland Cropland

Upland croplands are adjacent to nearly every leveed waterway within the Delta. EWA agencies do not propose to acquire water through crop idling actions in the Delta Region.

10.1.3.13 Seasonally Flooded Agriculture

Approximately 20,000 to 30,000 acres of field crops and grain are post-harvest flooded each winter in the Central Delta (USFWS 2000). EWA agencies do not propose to acquire water through crop idling actions in the Delta Region.

10.1.4 Export Service Area

The Export Service Area includes Anderson Reservoir, San Luis Reservoir, the southern San Joaquin Valley, and portions of southern California focused on the following EWA actions:

- Crop idling within the export service area region would be limited to cotton fields in Fresno, Kings, Tulare, and Kern Counties.

- Groundwater substitution transfers initiated by EWA agencies would occur on farms primarily within the Tulare Basin and the jurisdiction of the Kern County Water Agency.

- Groundwater storage transfers initiated by EWA agencies would occur within the Semitropic Water Storage District and the Arvin-Edison Water Storage District. These water districts use San Luis Reservoir to obtain water for groundwater substitution and groundwater purchase actions.

- San Luis Reservoir can also provide borrowed project water for EWA actions when necessary. (See Section 2.4.2.3.2.)

- Source-shifting agreements to be made with Metropolitan Water District (Metropolitan WD) of Southern California and potentially affecting Metropolitan Water District and SWP facilities. Water supplies sent downstream of the Delta are routed through the San Luis Reservoir to southern California via the California Aqueduct. Within the export service area, the EWA agencies would conduct source-shifting actions using Metropolitan Water District storage facilities (Diamond Valley Lake and Lake Mathews [Metropolitan Water District owned]; Castaic Lake, Silverwood Lake, and Lake Perris [State Water Project owned]); and groundwater storage programs (Semitropic, Arvin-Edison, and Hayfield); and, Santa Clara Valley Water District (Anderson Reservoir).

These areas are predominantly agricultural (cotton, dairy, safflower, wheat, and citrus orchards) and urban environments (such as Fresno, Bakersfield, and Los Angeles). Land left for natural habitats consists mostly of non-native annual grasslands in the San Joaquin Valley and upland scrub or desert habitats in Southern California. Many native habitats of the San Joaquin Valley have declined dramatically in size and quality with the rise of the agricultural industry and urban development.

The sections below describe the NCCP habitats within the Export Service Area. Descriptions for each habitat, including the dominant vegetation, have been given in Section 10.1.2. Where this description differs from that provided in Section 10.1.2, it

will list location of the habitat within the Export Service Area, and the wildlife and special-status species associated with each habitat.

10.1.4.1 Lacustrine

Lacustrine habitats in the Export Service Area include Anderson Reservoir, San Luis Reservoir, Castaic Lake, Lake Perris, Lake Mathews, and Diamond Valley Lake.

10.1.4.1.1 Wildlife

Wildlife found within lacustrine habitat include belted kingfisher, Caspian tern, ring-billed gull, Clark's grebe, western grebe, pied-billed grebe, osprey, common egret, spotted sandpiper, and killdeer. Other birds include white-throated swift, cliff swallow, violet-green swallow, northern rough-winged swallow, and various tern, loon, and waterfowl species such as teal, northern shoveler, pintail, and Canada geese.

10.1.4.1.2 Special-Status Species

Special-status species associated with lacustrine habitats in the Export Service Area includes: Aleutian Canada goose, American peregrine falcon, California gull, great blue heron, osprey, double-crested cormorant, bald eagle, western pond turtle, California red-legged frog, and California tiger salamander.

10.1.4.2 Nontidal Freshwater Permanent Emergent

Elizabeth Canyon at Castaic Lake provides for shallow sandy ledges. A high water associated with the lake table support hydrophilic vegetation (Entrix 1996). Intermittent and perennial tributaries of Castaic Lake support small isolated patches of freshwater emergent wetland habitat.

10.1.4.2.1 Wildlife

Wildlife associated with NFPE habitats can be found in Section 10.1.2.4.

10.1.4.2.2 Special-Status Species

Special-status species associated with NFPE habitats can be found in Section 10.1.2.4.

Special-status plant species associated with NFPE in the Export Service Area includes slough thistle, Hispid's bird's beak, California beaked-rush, and Sanford's arrowhead.

10.1.4.3 Valley/Foothill Riparian

This habitat generally occurs at the shorelines and in association with tributaries that enter the lakes. The eastern shoreline of Lake Perris includes an extensive riparian canopy with a well-developed understory. At San Luis Reservoir riparian habitat was limited to scattered patches of mule fat and occasional willows. Riparian habitat at Anderson Reservoir occurs along tributaries.

10.1.4.3.1 Wildlife

Wildlife associated with VFR habitats in the Export Service Area include black phoebe, red-winged blackbird, brewer's blackbird, ash-throated flycatcher, northern rough-winged swallow, scrub jay, black headed grosbeak, California quail, Nuttall's

woodpecker, plain titmouse, California towhee, Merriam's chipmunk, mule deer, coyote, black bear, mountain lion, and raccoon.

10.1.4.3.2 Special-Status Species

Special-status species associated with VFR habitats can be found in Section 10.1.2.7.

Special-status plant species includes slough thistle and northern California black walnut.

10.1.4.4 Grassland

Non-native annual grasslands surround San Luis Reservoir and portions of Anderson Reservoir. These non-native grasses are mixed with native species such as purple needle grass, creeping wild rye, and onion grass.

10.1.4.4.1 Wildlife

Grassland wildlife includes killdeer, white-throated swift, ring-necked pheasant, American crow, rufous-crown sparrow, rock wren, western meadowlark, red-tailed hawk, American kestrel, common loon, American white pelican, Barrow's goldeneye, savannah sparrow, California vole, black-tailed jackrabbit, California ground squirrel, coyote, foxes, badgers, skunk, western rattlesnake, southern alligator lizard, two-striped garter snake, California mountain kingsnake, and western fence lizard.

10.1.4.4.2 Special-Status Species

Special-status grassland species around San Luis Reservoir include San Joaquin kit fox, American peregrine falcon, Swainson's hawk, California red-legged frogs (tributaries), Aleutian Canada goose, bald eagle, greater sandhill crane, California tiger salamander, foothill yellow-legged frog, western pond turtle, California horned lark, San Joaquin whipsnake, double-crested cormorant, long-billed curlew, California gull, osprey, northern harrier, Cooper's hawk, merlin, prairie falcon, white-tailed kite, ferruginous hawk, western burrowing owl, long-eared owl, loggerhead shrike, and San Joaquin pocket mouse.

Special-status plant species associated with grasslands in the Export Service Area includes: heartscale, brittlescale, San Joaquin spearscale, lesser saltscale, Lost Hills crownscale, Tiburon Indian paintbrush, recurved larkspur, Hoover's eriastrum, spiny-sepaled button-celery, Hall's tarplant, Congdon's tarplant, pale-yellow layia, San Joaquin woolythreads, Panoche peppergrass, red-flowered lotus, showy madia, Merced phacelia, Hartweg's golden sunburst, San Joaquin adobe sunburst, rock sanicle, most beautiful jewel-flower, and showy Indian clover.

10.1.4.5 Upland Scrub

Upland scrub habitat occurs on the slopes and shorelines surrounding Lakes Perris and Mathews, Castaic and Diamond Valley Lakes, and Anderson Reservoir. This habitat consists of mixed chapparal and coastal scrub vegetation including chamise, scrub oak, big berry manzanita, mountain mahogany, yucca, and big pod ceanothus. Blue elderberry is infrequent. Upland scrub also includes purple sage, white sage, rabbit brush, California sage, and California buckwheat.

10.1.4.5.1 Wildlife

Wildlife associated with upland scrub habitats in the Export Service Area includes scrub jay, common raven, greater roadrunner, Anna's hummingbird, mourning dove, song sparrow, western fence lizard, granite spiny lizard, black bear, bobcat, mountain lion, Merriam's chipmunk, California ground squirrel, western rattlesnake, coast horned lizard, and alligator lizard.

10.1.4.5.2 Special-Status Species

Special-status upland scrub species around Castaic Lake include arroyo toad and California red-legged frog (tributaries), California newt, foothill yellow-legged frog, San Diego horned lizard, western pond turtle, Cooper's hawk, northern harrier, sharp-shinned hawk, golden eagle, osprey, prairie falcon, and loggerhead shrike.

Special-status upland scrub species around Lake Perris, Lake Mathews, and Diamond Valley Lake include Stephen's kangaroo rat, western spadefoot toad, San Diego horned lizard, double-crested cormorant, Cooper's hawk, osprey, golden eagle, northern harrier, sharp-shinned hawk, loggerhead shrike, short-eared owl, burrowing owl, yellow warbler, and yellow-breasted chat.

Special-status plant species associated with upland scrub habitats in the Export Service Area includes: San Benito evening-primrose, Shrasmith's harebell, tree anemone, Mt. Hamilton coreopsis, Brandegee's eriastrum, Ben Lomond buckwheat, Hall's bush mallow, San Antonio Hills mondarella, Mt. Diablo phacelia, rock sanicle, most beautiful jewel-flower, Mt. Hamilton jewelflower, Coyote ceanothus, and Arburua Ranch jewelflower.

10.1.4.6 Valley/Foothill Woodland and Forest

Scattered blue oak woodlands occur on the western shore of the San Luis Reservoir. Isolated patches of coast live oak woodland occur at scattered locations in association with upland scrub habitats at Castaic Lake. The hillsides adjacent to Anderson Reservoir display a combination of blue oak/foothill pine and coast live oak woodlands.

10.1.4.6.1 Wildlife

Wildlife associated with VFW habitats includes acorn woodpecker, northern flicker, wild turkey, plain titmouse, black-tailed jackrabbit, American crow, California quail, western fence lizard, coyote, mule deer, western bluebird, white-breasted nuthatch, and American kestrel.

10.1.4.6.2 Special-Status Species

Special-status species associated with VWF are listed in Section 10.1.2.11.

Special-status plant species includes, Sharsmith's onion, Big Bear Valley woolypod, San Benito evening-primrose, tree anemone, Mt. Hamilton coreopsis, recurved larkspur, Brandegee's eriastrum, Ben Lomond buckwheat, Hall's tarplant, pale-yellow layia, Madera linanthus, red-flowered lotus, showy madia, San Antonio Hills monardella, Mt. Diablo phacelia, rock sanicle, and Mt. Hamilton jewelflower.

10.1.4.7 Upland Cropland

Upland cropland areas are found throughout the San Joaquin Valley. However, EWA water acquisition actions will only involve cotton fields in the San Joaquin Valley.

"Cotton is of limited value to wildlife because of the intensive management of this crop and the use of chemicals to control pests and disease. Mourning doves and house mice are found in this crop type. During irrigation when vegetation is short and sparse additional wildlife including killdeer, American pipet, and horned lark may be attracted (CALFED 1998)." Associated agricultural ditches are also treated with chemicals to control vegetation, making these ditches also less suitable for wildlife. Figure 10-6 is a picture of cotton farmland habitat.

Figure 10-6
Upland Cropland – Cotton Habitat

10.2 Environmental Consequences/Environmental Impacts

The following section evaluates the effects of the EWA alternatives on vegetation and wildlife. This section includes discussions on the following topics:

- Special-status species and NCCP communities included in the effects analysis;
- Methods used to assess effects of EWA program actions;
- Conservation measures posed to avoid or minimize effects of EWA actions on vegetation and wildlife;
- Effects of each alternative on NCCP habitats and associated wildlife in the area of analysis;
- Comparison of each alternatives' effects on the NCCP habitats and associated wildlife; and
- Analysis of the cumulative effects on the NCCP habitats and associated wildlife.

10.2.1 NCCP Communities and Special-Status Species Addressed in the EIS/EIR and ASIP

To comply with NEPA, CEQA, ESA, CESA, and NCCPA requirements, the EWA agencies must identify a list of NCCP communities and special-status species for evaluation in the EWA EIS/EIR and ASIP. The following section describes the processes for selecting NCCP habitats and special-status species for analysis.

10.2.1.1 Identification of NCCP Communities Analyzed

A total of twenty natural communities were analyzed on a broad, programmatic basis in the MSCS – 18 habitats and two ecologically based fish groups. The term "NCCP communities" refers to both NCCP habitats and fish groups. Chapter 9 of this EIS/EIR analyzes the fish groups. This EIS/EIR includes addresses 15 of the 18 NCCP habitats analyzed in the MSCS.

10.2.1.1.1 Determining the Likelihood that EWA Actions would Affect NCCP Habitats

EWA actions were considered likely to affect evaluated habitats adversely or beneficially:

- If the quality of the habitat to support populations of species is changed;
- If habitat of a species, critical to the viability of the population, is present in the area where actions could be implemented;
- Implementing one or more actions may affect or could result in take of the species; or
- Implementing the actions would increase or decrease the extent or quality of habitat potentially occupied by the species.

Out of the 20 community types, this EIS/EIR does not evaluate five community types for the reasons given below. Detailed descriptions of the 20 habitats, including their assigned conservation goal from the MSCS, can be found in the EWA ASIP Chapter 5 and Appendix A of the EWA ASIP, which are included as Appendix H of this EIS/EIR.

10.2.1.1.2 Grassland

EWA actions would not affect this habitat because the root zone of the plant species is elevated above any EWA water acquisition/management-induced groundwater and reservoir level change. EWA actions would not lead to restoration of the function of this habitat.

10.2.1.1.3 Upland Scrub

EWA actions will not affect this habitat because the root zone of the plant species is elevated above any EWA water acquisition/management -induced groundwater and reservoir level change. EWA actions will not lead to restoration of the function of this habitat.

10.2.1.1.4 Valley/Foothill Woodland and Forest

EWA actions will not affect this habitat because the root zone of the plant species is elevated above any EWA water acquisition/management -induced groundwater and reservoir level change. EWA actions will not lead to the restoration of this habitat.

10.2.1.1.5 Montane Woodland and Forest

EWA actions will not affect this habitat because the root zone of the plant species is elevated above any EWA water acquisition/management -induced groundwater and reservoir level change. EWA actions will not lead to the restoration of this habitat.

10.2.1.1.6 Inland Dune Scrub

EWA actions will not affect this habitat because the root zone of the plant species is elevated above any EWA water acquisition/management -induced groundwater and reservoir level change. EWA actions will not lead to the restoration of this habitat.

10.2.1.2 Identification of Species to be Analyzed

The analysis includes the special-status species that fit into at least one of the following categories and potentially occur in the EWA Asset Acquisition and Management Areas (Figure 2-3):

- Listed as threatened or endangered under FESA;
- Proposed for listing under FESA;
- Candidates for listing under FESA;
- Listed as threatened or endangered under CESA;
- Candidates for listing under CESA;
- Plants listed as rare under the California Native Plant Protection Act;
- Fully protected species or specified birds under various sections of the California Fish and Game Code;
- California species of special concern (CSC);
- Plants included on California Native Plant Society (CNPS) List 1 A, lB, 2, or 3;
- Other native species of concern to CALFED; or
- Aquatic species with designated Essential Fish Habitat within the area of analysis.

Pursuant to Section 7(c) of ESA, the EWA agencies requested species lists from USFWS, NOAA Fisheries, and CDFG regarding any species listed or proposed for listing as threatened or endangered, including designated or proposed critical habitats under ESA and CESA that may be present in the EWA area of analysis. Additionally, the EWA agencies developed a list of special-status species known to occur or with

the potential to occur within the area of analysis compiled from the California Natural Diversity Database (CNDDB) and California Native Plant Society's Inventory of Rare and Endangered Plants. More than 400 special-status fish, wildlife, and plant species considered[4] in the MSCS were combined with the results from the species request lists and the database search to generate a preliminary species list. (See EWA ASIP, Table A-1.)

Species included in this preliminary species list were then screened to identify all species that occur outside of the area of analysis. Additional species were screened out because they occur in habitats that the EWA actions would not affect (as described in Section 1.4.2 of the ASIP).

The final selection process determined which special-status species should be included based on several considerations that helped determine if EWA asset acquisition and management actions could affect the species or the habitat of listed species[5]. After all of the screening steps, this EIS/EIR and EWA ASIP includes the following species:

- MSCS covered terrestrial species whose life cycles are dependent on seasonally flooded agricultural land;
- MSCS covered species that extensively use agriculture water supply/return ditches as habitat; and
- MSCS covered species that use seasonally flooded agriculture land for a portion of their life cycle (e.g., nesting/forage during the summer, over-winter forage for winter migrants).

Species that are analyzed in detail in the EWA ASIP are described in relation to their association with seasonally flooded agricultural land below. These species include the Aleutian Canada goose, black tern, black-crowned night heron, great blue heron, great egret, greater sandhill crane, long-billed curlew, snowy egret, tricolored blackbird, white-faced ibis, giant garter snake, and western pond turtle.

Aleutian Canada Goose: During the winter, the Aleutian Canada Goose forages on post-harvest wastegrain, among other items, in the Sacramento Valley.

Black Tern: The black tern uses rice fields, primarily in Glenn and Colusa Counties for both nesting and foraging.

---

4 Actions considered by CALFED when analyzing effects in the PEIS/EIR and MSCS did not include crop idling; therefore, this ASIP used the list of MSCS considered species as a basis for its preliminary species list rather than the list of MSCS evaluated species.

5 Based on the description of the Flexible Purchase Alternative provided in Chapter 2 the following EWA actions are most likely to affect MSCS covered species: 1) the pumping of EWA assets to the Export Service Area, 2) reduction in Delta outflows, 3) changes in timing of releases of water from reservoirs, and 4) crop idling involving seasonally flooded agriculture (rice).

Black-crowned Night Heron: The black-crowned night heron forages along irrigation canals and other waterways associated with rice crops throughout the Sacramento Valley.

Great Blue Heron: The great blue heron forages along irrigation canals and other waterways associated with rice crops throughout the Sacramento Valley.

Great Egret: The great egret has similar life history requirements as the great blue heron.

Greater Sandhill Crane: During the winter, the greater sandhill crane forages on waste grain remaining in fields following the harvesting of the rice crop, particularly in the Butte Basin.

Long-billed Curlew: The Long-billed Curlew uses rice fields to forage for invertebrates during the winter.

Snowy Egret: The snowy egret has similar life history requirements as the great blue heron and great egret.

Tricolored Blackbird: The tricolored blackbird forages on grain provided by rice along with insects.

White-faced Ibis: The white-faced ibis uses rice fields to forage for invertebrates during the winter.

Giant Garter Snake: In some portions of the Sacramento Valley, the giant garter snake is highly dependent upon rice fields for the majority of its habitat requirements.

Western Pond Turtle: The western pond turtle uses irrigation and drainage ditches adjacent to rice fields for resting and foraging habitat.

10.2.1.3 Description of Species Not Analyzed In Detail

Species are not included in this EIS/EIR if they may occasionally visit, but are not dependent on, seasonally flooded agriculture land (e.g., migrants or species with broad home ranges) and would not be affected by EWA crop idling actions. The following text lists those species and explains the rationale for the no effects determination. The EWA ASIP Appendix A (Appendix J to this EIS/EIR) presents additional details regarding the life histories and status of these species.

10.2.1.3.1 Western Spadefoot Toad

Levees and drainage ditches are potential habitat for the western spadefoot toad. They use ditch bottoms in the spring for breeding (at times when EWA idling actions would not be occurring) and the levee sides as habitat the remainder of the year. The EWA asset acquisition and management actions would not physically affect levees or the quantity of rainwater in ditches adjacent to rice fields.

10.2.1.3.2 Double-Crested Cormorant

Double-crested cormorant use levees adjacent to rice fields to dry their wings. EWA asset acquisition and management actions would not affect levees adjacent to rice fields.

10.2.1.3.3 American Bittern

American bitterns forage in flooded rice fields and adjacent irrigation ditches during the winter primarily for invertebrates. EWA asset acquisition and management actions would not prevent flooding of fields in the winter.

10.2.1.3.4 White-tailed Kite

During the winter, white-tailed kites forage for small rodents, insects, frogs, and snakes over flooded and idled rice fields. EWA asset acquisition and management actions would not prevent the winter flooding of fields. EWA actions have the potential to increase the overall acreage of idled rice fields increasing the forage base for this species. This potential benefit cannot be quantified and is not addressed further in this EIS/EIR.

10.2.1.3.5 Bald Eagle

Bald eagles forage for ducks, geese, and sometimes fish over large areas, including rice fields. This species, however, is highly mobile with a home range radius of approximately 1 mile, whereas the largest possible block of idled land will be 160 acres (½ mile X ½ mile). EWA asset acquisition and management actions would not reduce the forage supply of waterfowl and fish within the Sacramento Valley.

10.2.1.3.6 Swainson's Hawk

Swainson's hawks forage in idled rice fields. EWA asset acquisition and management actions have the potential to increase the overall acreage of idled rice fields, increasing the forage base for this species. This potential benefit cannot be quantified and is not addressed further in this EIS/EIR.

10.2.1.3.7 Ferruginous Hawk

Ferruginous hawks forage for small mammals in idled rice fields. EWA asset acquisition and management actions have the potential to increase the overall acreage of idled rice fields. This potential benefit cannot be quantified and is not addressed further in this EIS/EIR.

10.2.1.3.8 Golden Eagle

Golden eagles forage over large areas that include rice fields near their nests in the foothills surrounding the Central Valley. This species, however, is highly mobile with an extensive home range, whereas the largest possible block of idled land will be 160 acres (½ mile X ½ mile).

10.2.1.3.9 Merlin

During the winter, merlins forage for songbirds and shorebirds over flooded and idled rice fields. EWA asset acquisition and management actions would not prevent the winter flooding of fields. EWA actions have the potential to increase the overall

acreage of idled rice fields. This potential benefit cannot be quantified and is not addressed further in this EIS/EIR.

10.2.1.3.10 Peregrine Falcon

During the winter, peregrine falcons forage for ducks and shorebirds over flooded and idled rice fields. EWA asset acquisition and management actions would not prevent flooding of fields. EWA actions have the potential to increase the overall acreage of idled rice fields. This potential benefit cannot be quantified and is not addressed further in this EIS/EIR.

10.2.1.3.11 Prairie Falcon

During the winter, the prairie falcon forages over flooded and idled rice fields. EWA asset acquisition and management actions would not prevent flooding of fields. EWA actions have the potential to increase the overall acreage of idled rice fields.

10.2.1.3.12 Mountain Plover

The mountain plover uses disced rice fields in late winter to find insects. EWA asset acquisition and management actions would not prevent disking of these fields, which would ensure forage habitat is maintained for the mountain plover.

10.2.1.3.13 Short-eared Owl

The short-eared owl could find a suitable prey base in idled rice fields. EWA asset acquisition and management actions have the potential to increase the overall acreage of idled rice fields. This potential benefit cannot be quantified and is not addressed further in this EIS/EIR.

10.2.1.3.14 Northern Harrier

The northern harrier could find a suitable prey base in idled rice fields. EWA asset acquisition and management actions have the potential to increase the overall acreage of idled rice fields. This potential benefit cannot be quantified and is not addressed further in this EIS/EIR.

10.2.1.3.15 Long-eared Owl

Long-eared owls can be found in trees along rice fields and forage over idled fields at night. EWA asset acquisition and management actions have the potential to increase the overall acreage of idled rice fields and would not affect woodlands.

10.2.1.3.16 Burrowing Owl

Burrowing owls can be found on the levees bordering rice fields. EWA asset acquisition and management actions would not affect these levees.

10.2.1.3.17 Bank Swallow

During the spring and summer, bank swallows can be found foraging for insects over rice fields. This species, however, is highly mobile with a foraging range of 8-10 km, whereas the largest possible block of idled land will be 160 acres (½ mile X ½ mile).

10.2.1.3.18 Bewick's Wren

Bewick's wrens are casual visitors to rice fields in the fall and winter. They are sometimes found feeding along weedy irrigation ditches or in idled rice fields. EWA asset acquisition and management actions would not affect irrigation ditches and would increase the acreage of idled rice fields.

10.2.1.3.19 Loggerhead Shrike

Loggerhead shrikes can be found hunting along the borders of rice fields and in idled rice fields. EWA asset acquisition and management actions would increase the acreage of idled rice fields and would not affect adjacent ditches.

10.2.1.3.20 Lark Sparrow

Lark Sparrows are casual visitors to rice fields in the fall and winter. They are sometimes found feeding along weedy irrigation ditches or in idled rice fields. EWA asset acquisition and management actions would increase the acreage of idled rice fields and would not affect adjacent ditches.

Terrestrial species that may be associated with lacustrine habitats (lakes, ponds, oxbows, gravel pits), such as bald eagles and osprey, are also not included because the analysis of EWA actions produced no adverse affect to fish populations (see Chapter 9), which can be a primary food source.

10.2.2 Assessment Methods

The assessment methods used for this analysis address effects on vegetation and wildlife, special-status species, and NCCP communities caused by implementation of EWA actions. The EWA ASIP (Appendix J) presents additional information on special-status species and associated habitats. ASIP preparation satisfies compliance with the state and federal endangered species laws.

EWA actions to benefit fish include pump reductions, Delta cross channel closure, instream flow increases, and Delta outflow augmentation. EWA asset acquisition and management actions include pre-delivery, source shifting, purchasing stored reservoir water, using groundwater substitution and/or storage, purchasing stored groundwater, and crop idling. These actions may affect the following variables: 1) the timing of water releases, 2) river flows, 3) reservoir levels, 4) water table levels, or 5) the number of acres of seasonally flooded land. Effects to plant communities may include changes in water availability, alteration of species composition, and removal, conversion, or fragmentation of communities. Changes in the quantity or quality of habitat, loss of forage and cover, and fragmentation of habitat could affect wildlife species.

This section analyzes effects to vegetation, wildlife, and NCCP communities at a community level; that is, this analysis assumes that if the EWA asset acquisition and management actions adversely affect an NCCP community, then the EWA asset acquisition and management actions would also adversely affect any species associated with that community. Where necessary, this analysis evaluates effects to

special-status species both on a community and species level. Additional details regarding the NCCP communities and special status species are presented in the ASIP.

10.2.2.1 Tidal Perennial Aquatic, Saline Emergent, and Tidal Freshwater Emergent Habitats

These three habitat types are found in portions of the Delta, and could potentially be affected by changes in magnitude and timing of Delta flows, which could also affect Delta water quality. The CALSIM II model simulates Delta inflows, Delta outflows, and Delta exports with and without the EWA program. CALSIM provides monthly flow data, which does not reflect the daily tidal variations that occur within the Delta. To determine more Delta-specific effects, DWR's Delta Simulation Model (DSM) 2 calculated Delta water quality and flow data at a more detailed level. Attachment 1 to this EIS/EIR describes these modeling efforts in greater detail. Model results were used to compare the frequency and magnitude of changes within the Delta to determine if these changes could affect Tidal Perennial Aquatic, Saline Emergent, or Tidal Freshwater Emergent Habitats or the species that depend on them.

10.2.2.2 Nontidal Freshwater Permanent Emergent

Within the Delta, the methods of assessing impacts to the Nontidal Freshwater Permanent Emergent habitat are the same as for the Tidal Freshwater Emergent, Upstream from the Delta, where this community may be supported by an elevated groundwater table, the lowering of the water table as part of groundwater substitution could affect this habitat. The effects analysis considers groundwater level changes from groundwater substitution, and a geographic comparison of the potential groundwater changes to areas with Nontidal Freshwater Permanent Emergent habitat.

10.2.2.3 Valley Riverine Aquatic, Montane Riverine Aquatic, Valley/Foothill Riparian, and Montane Riparian Habitats

EWA actions could affect these habitat types by changing the timing and volume of flows within rivers. The sections below describe how the flows were determined for each river.

10.2.2.3.1 Sacramento, Lower Feather, and Lower American Rivers

The analysis of potential effects on these habitats associated with rivers that are part of the CVP and SWP systems utilized the hydrologic modeling results. Attachment 1, the Modeling Description, provides a discussion of the hydrologic modeling process and its application to the EWA program analysis, including 1) the primary assumptions and model inputs that represent hydrologic, regulatory, structural and operational conditions; and 2) the model simulations that helped derive effects. For these rivers, modeling results were based on the maximum assets contained in Table 2-5, rather than available pump capacity as was used in Chapter 9.

10.2.2.3.2 Yuba, Upper Feather, Upper American, and Merced Rivers

These rivers are not a part of the CVP or SWP systems, and are therefore not included in the CALSIM II model. Attachment 1, the Modeling Description, describes the alternative methodology used to calculate changes in monthly operations based on historic water river flow data gathered from USGS. The effects analysis compares the changes in river flows to the surrounding vegetation to determine if the changes would affect these habitat types.

10.2.2.4 Lacustrine

EWA water storage and management actions involving reservoirs would alter reservoir levels compared with the Baseline, potentially causing effects to the lacustrine community. Fluctuations in reservoirs levels as a result of EWA asset storage and releases, if significantly different from the Baseline Conditions of the reservoirs could affect vegetation and associated wildlife species that are established at or near the water surface and within the drawdown zone and are not accustomed to the changes in reservoir levels. The sections below discuss the analysis methodologies for the rivers within the area of analysis.

10.2.2.4.1 CVP and SWP Reservoirs (Shasta, Oroville, and Folsom Reservoirs)

The analysis of potential effects on lacustrine habitat associated with CVP and SWP reservoirs utilized the hydrologic modeling results. Attachment 1, the Modeling Description, provides a discussion of the hydrologic modeling process and its application to the EWA program analysis, including 1) the primary assumptions and model inputs that represent hydrologic, regulatory, structural and operational conditions; and 2) the model simulations that helped derive effects.

10.2.2.4.2 Upstream from the Delta Non-Project Reservoirs

Several non-Project reservoirs upstream of the Delta (Little Grass Valley, Sly Creek, New Bullards Bar, French Meadows, Hell Hole, Lake McClure) could sell water to the EWA agencies. Because the CVP and SWP do not manage these non-Project reservoirs, the CALSIM II hydrologic modeling simulations do not reflect these reservoir operations. Attachment 1, the Modeling Description, describes the alternative methodology used to calculate changes in monthly operations based on historic water storage data. The effects analysis compares the rate of changes in storage and elevation to the surrounding vegetation to determine if the reservoir changes would affect the lacustrine community.

10.2.2.5 Natural Seasonal Wetland

High groundwater levels can create Natural Seasonal Wetlands; therefore, if the EWA asset acquisition and management actions decrease groundwater levels, this change could affect this habitat type. The specific locations in the Sacramento and San Joaquin valleys where groundwater substitution and groundwater purchase could occur are not currently identified and can vary year to year based on EWA water acquisition strategies and willing sellers. Mitigation measures proposed for groundwater actions (Chapter 6) may preclude this effect, but the groundwater measures have not been tested and there is no current mechanism for assessment of

the effect because specific locations for groundwater actions are not known. Therefore, the effect of the EWA water acquisitions can only be assessed in a qualitative sense.

10.2.2.6 Managed Seasonal Wetland

The EWA agencies have not identified the specific locations in the Sacramento and San Joaquin valleys where crop idling and groundwater substitution transfers could occur because they can vary year to year based on the location of willing sellers and EWA water acquisition strategies. Therefore, the following section assesses the effect of the EWA water acquisitions in a qualitative sense.

To determine if groundwater substitution transfers affect water in ditches, the analysis qualitatively examines the process that water agencies would use to sell water to the EWA agencies to determine if this process could decrease the water available to managed seasonal wetlands. Return flows may decrease if farmers idle lands that are upstream of managed seasonal wetlands. The analysis qualitatively examines the likelihood that crop idling would reduce flows within agricultural ditches, and compares the locations of ditches with decreased flows to wetlands that receive water from the same sources.

10.2.2.7 Upland Cropland

The impact assessment methods for this community were based on the relative value of a particular crop as wildlife habitat and forage. The EWA agencies propose to purchase water that would have been used to irrigate cotton farmland. This would idle the land, resulting in bare fields. Neither the cotton land nor bare field would provide for significant wildlife habitat. Dust suppression plans may involve the use of a substitute crop, providing some wildlife value. The EWA agencies are not specifically requiring farmers to substitute other crops; therefore, crop substitution is not factored into the effects analysis. However, because cotton land provides extremely marginal habitat and forage, the effects analysis does not assess the EWA's asset acquisition and management action effects on this habitat.

10.2.2.8 Seasonally Flooded Agriculture

Potential effects on special-status species associated with SFA were determined based on an analysis of changes in the amount of habitat and forage provided by rice fields within each county having water agencies that potentially would sell water to EWA agencies.

10.2.2.8.1 Changes in Habitat Availability

This SFA effects analysis addresses water acquisitions that would result in the maximum potential quantities available from crop idling. The SFA impact analysis includes the following steps:

- Derivation of the acquisition quantity for each county by the evapotranspiration of applied water[6] to determine the amount of idled acreage required to obtain the acquisition amount;

- Comparing the total acreage required for EWA crop idling to the amount in the rice land in the 1997 Agricultural Census data to obtain the change in rice acreage per county; and

- Calculating the absolute and relative change in rice habitat availability using the changes in rice acreage numbers.

The analysis presents change in rice habitat availability both as an absolute quantity (number of acres) and relative value (percent of rice acreage).

10.2.2.8.2 Changes in Forage Availability

Waste grain remaining after rice harvest serves as a food resource for wildlife species, including the special-status species associated with rice fields identified in Table 10-3. Consequently, changes in the amount of rice acreage would change the availability of forage for special-status species associated with rice fields. Each acre of rice provides approximately 300 to 350 pounds per acre (lbs/ac) of waste grain (Brouder and Hill 1995). Although newer technologies used for harvesting generate less waste grain per acre, this analysis uses 350 lbs/acre to provide a conservative estimate for the amount of waste grain lost due to rice idling (Brouder and Hill 1995). This analysis presents the total amount of waste grain lost due to rice idling for each county, and expressed as an absolute quantity (lbs) and relative value (percent of forage provided by rice in the county).

Rice fields also provide approximately 250 lbs/ac of other food (not waste rice grain), which is comprised primarily of invertebrates (Brouder and Hill 1995). This analysis assumed that some plant species (weeds and other plant species that could colonize idled fields) and invertebrates would still be available in idled fields, and that crop idling would not substantially reduce this food source. Accordingly, potential effects on other food available to wildlife species were considered to be insignificant and are not further analyzed in this section.

10.2.2.8.3 Habitat Fragmentation

A decrease in the availability of SFA under the EWA program has the potential to contribute to fragmentation and isolation of wetland habitats within an individual county on a temporary basis. Because the EWA is a program, and the specific fields where idling will occur cannot be predicted and will change from year to year, the degree of fragmentation within a county cannot be quantified. In addition, EWA program crop idling actions are dependent upon hydrologic year type and more than likely will not occur every year. Consequently, this section does not include an analysis of habitat fragmentation and isolation. Potential temporary fragmentation

---

[6] The Evapotranspiration of Applied Water (ETAW) represents the amount of applied water that is used by the crop for evapotranspiration. This number is defined in Section 2, Program Description, and is approximately 3.3 acre-feet per acre for rice.

and isolation effects, however, will be avoided through crop idling conservation measures. Specifically, the EWA agencies will minimize crop idling in adjacent fields within each county.

10.2.3 Significance Criteria

Under criteria based on State CEQA Guidelines and the CALFED Programmatic EIS/EIR, the proposed project would be considered to have a significant effect on vegetation and wildlife if it would result in any of the following:

- Adversely affect, either directly or through habitat modifications, any endangered, rare, or threatened species, as listed in Title 14 of the California Code of Regulations (sections 670.2 or 670.5) or in Title 50, Code of Federal Regulations. (See sections 17.11 or 17.12;)

- Have a substantial adverse impact, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special status species in local or regional plans, policies, or regulations, or by the California Department of Fish and Game or U.S. Fish and Wildlife Service;

- Cause a reduction in the area or habitat value of critical habitat areas designated under the federal ESA;

- Substantially fragment or isolate wildlife habitats or movement corridors, especially riparian and wetland habitats, or impede the use of wildlife nurseries;

- Have a substantial adverse impact, such as a reduction in area or geographic range, on any riparian habitat, other sensitive natural community, or significant natural areas identified in local or regional plans, policies, regulations, or by the California Department of Fish and Game or U.S. Fish and Wildlife Service;

- Adversely affect federally protected wetlands (including, but not limited to, marsh, vernal pool, coastal, etc.) either individually or in combination with the known or probable impacts of other activities through direct removal, filling, hydrological interruption, or other means;

- Substantially decrease the size of important native upland wildlife habitats or wildlife use areas; and

- Substantially decrease the amount of available forage, including forage from agricultural lands for wintering waterfowl.

10.2.4 Environmental Measures Incorporated into the Program

Environmental measures applicable to the EWA actions for each species and NCCP habitat that have been incorporated into the program description are described in this section. The MSCS also includes programmatic conservation measures for each species and NCCP community.

10.2.4.1 Environmental Measure Applicable to all Species

The EWA Project agencies will coordinate EWA water acquisition and transfer actions with Federal (Reclamation, USFWS and NOAA Fisheries), State (DWR and CDFG), other CALFED agencies, and regional programs (e.g., the San Francisco Bay Ecosystem Goals Project, the Anadromous Fish Restoration Program, the Senate Bill [SB] 1086 program, the U.S. Army Corps of Engineers' (USACE's) Sacramento and San Joaquin Basin Comprehensive Study, the Riparian Habitat Joint Venture, the CVPIA, the Central Valley Habitat Joint Venture, and the Grassland Bird Conservation Plan) that could affect management of evaluated species. Coordination would avoid conflicts among management objectives and would be facilitated through CALFED's water transfer program.

10.2.4.1.1 Giant Garter Snake (T-FESA; T-CESA)

Within the Sacramento River valley, the giant garter snake (GGS) is highly dependent on rice fields and associated irrigation ditches. EWA actions, or cumulatively, water acquisitions, could idle up to 20 percent of flooded rice fields in each county. The following text provides the proposed approach and conservation measures to protect the GGS.

As part of the EWA consultation, the USFWS will give programmatic approval to crop idling, followed by a site-specific consultation process to ensure consistency with the programmatic approval. The programmatic consultation will include three main elements: 1) the process by which site-specific agreements will be attained; 2) the list of conservation measures (avoidance, minimization, and conservation measures) which would be used wholly or in part to minimize effects of water transfers involving fallowing or crop-shifting; and 3) a description of GGS conservation strategy in Chapter 4 of this ASIP.

USFWS EWA consultation with the Project Agencies will outline a year-by-year "site specific" process to address crop idling impacts to GGS and will put boundaries on upper limit on the amount of crop idling that may occur in any given year, considering the existing 20 percent limit. Additional measures to those presented in this EIS/EIR may be incorporated as a part of consultation based on site-specific conditions.

Each year, once it has been determined that crop idling will occur, the EWA Project Agencies will contact USFWS staff to begin informal consultation and will put together a package describing where the idling activities will take place and what proposed minimization measures will be followed. This package will include maps of the proposed idled fields. USFWS will work with the EWA Project Agencies to determine if minimization measures proposed are sufficient and if additional compensatory habitat is required.

The EWA agencies will ensure through contract terms or other requirements that the following conservation measures will be implemented:

- The EWA agencies will ensure parcels from which water is to be acquired are outside of mapped proscribed areas (see ASIP Figure 3-11), which include:

    - *Refuges* – Land adjacent and within 1 mile of Sacramento, Delevan, Colusa, Sutter, and Butte Sink National Wildlife Refuge (NWR), and the Llano Seco Unit of the Sacramento River NWR, Gray Lodge Wildlife Area (WA), Upper Butte Basin WA, Yolo Bypass WA, and Gilsizer Slough CE;

    - *Corridors Between Refuges* – Lands adjacent to Hunters and Logan Creeks between Sacramento River NWR and Delevan NWR; Colusa Basin Drainange Canal between Delevan NWR and Colusa NWR; Little Butte Creek between Llano Seco units of Sacramento River NWR and Upper Butte Basin WA, and Howards Slough Unit of the Upper Butte Basin WA, Butte Creek Upper Butte Basin WA, and Gray Lodge WA;

    - *Waterways Serving as Corridors* – Land adjacent to Butte Creek, Colusa Basin Drainage Canal, Gilsizer Slough, land side toe drain along east side of the Sutter Bypass, Willow Slough and Willow Slough Bypass in Yolo County, North Drainage Canal and East Drainage Canal in Natomas Basin

    - *Other Core Areas* – East of SR99 and between Sutter-Sacramento County line and Elverta Road in Natomas Basin, Yolo County east of Highway 113;

- The water seller will ensure that water is maintained in irrigation and drainage canals to provide movement corridors;

- The water agency will ensure that the block size of idled rice parcels will be limited to 160 acres (includes rice fields shifting to another crop);

- The water agency will ensure that mowing along irrigation and drainage canals will be minimized and mowers will be elevated to at least 6 inches above the ground level;

- The water agency will ensure that, if canal maintenance such as dredging is required, vegetation will be maintained on at least one side; and

- The EWA agencies will maximize geographic dispersal of idled lands.

GGS conservation measures may include the following, as appropriate:

- The EWA agencies will avoid purchasing water from the same field for more than two consecutive years;

- The EWA agencies will recommend that sellers replace culverts already planned for repair or replacement with oversized culverts to facilitate better wildlife dispersal;

- The EWA agencies will recommend that sellers replace water control structures with those requiring less maintenance and less frequent replacement in order to minimize maintenance impacts (steel or wooden control boxes with pre-poured concrete boxes); and

- The water agencies may fund research or surveys.

10.2.4.1.2 Greater Sandhill Crane (T/FP-CESA)

Crop idling of seasonally flooded agricultural land could reduce the amount of over winter forage for migratory birds.

- Avoid or minimize actions near known wintering areas in the Butte Sink (from Chico in the north to the Sutter Buttes, and from Sacramento River in the west to Highway 99) that could adversely affect foraging and roosting habitat.

10.2.4.1.3 Black Tern (SSC-CDFG)

Crop idling of seasonally flooded agricultural land could reduce the amount of nesting and forage habitat during the summer rearing season.

- As part of the review process for the identification of areas acceptable for crop idling, the Management Agencies will review current species distribution/occurrence information from the Natural Diversity Database and other sources (including rookeries, breeding colonies, and concentration areas). The Management Agencies will then use the information to make decisions that will avoid EWA crop idling actions that could result in the substantial loss or degradation of suitable habitat in areas that support core populations of evaluated species that are essential to maintaining the viability and distribution of evaluated species.

- As part of contractual agreements, the willing seller will be required to maintain quantities of water in agriculture return flow ditches that maintains existing wetland habitat providing habitat to the covered species.

10.2.4.1.4 Western Pond Turtle (SSC-CDFG)

Ditches and drains associated with rice fields provide suitable habitat for the western pond turtle. The following environmental measures would ensure effects of crop idling actions on western pond turtle habitat are avoided or minimized.

- The willing seller will be required to maintain water levels in irrigation and drainage canals to within 6 inches of non-program conditions and do not completely dry out canals.

10.2.4.1.5 Non-tidal Freshwater Permanent Emergent, Natural Seasonal Wetland, and Valley/Foothill Riparian Communities

Natural and Managed Seasonal Wetlands and Riparian Communities often depend on surface water-groundwater interactions for part or all of their water supply. The following environmental measures would ensure effects on these communities from groundwater substitution actions are avoided or minimized.

- **A Well Adequacy Review.** Before groundwater substitution actions the hydrogeologic conditions of wells used to transfer EWA water will be examined to minimize the potential risk of depleting surface water sources and adversely affecting associated vegetation; and

- **A Monitoring Program.** The Project Agencies will implement a monitoring program that will provide data to determine if direct or indirect effects exist.

10.2.4.1.6 Valley/Foothill Riparian and Montane Riparian Communities

Riparian plant germination, establishment, growth, and distribution are driven by water availability and floodplain and channel geomorphology that conform to historical patterns. The following environmental measure would ensure effects on these communities would be avoided or minimized.

- The EWA agencies will implement a monitoring program, in cooperation with other programs, that will provide flow data and observations of habitat changes to determine if changes in flows are having a direct or indirect effect on riparian communities, particularly establishment of seedlings and survival of middle age classes.

10.2.4.1.7 Managed Seasonal Wetlands

Landowners with managed seasonal wetland communities often depend upon agricultural return flows for part or all of their water supply. The following environmental measure would ensure effects on this wetland community would be avoided or minimized.

- As a part of the contractual agreements, the EWA agencies will require the willing seller of water for crop idling to maintain their drainage systems at a water level that would maintain existing wetlands providing habitat to covered species. As part of monitoring program to ensure compliance with the contractual requirements, EWA agencies will periodically verify that the seller is adhering to the agreement and that no effects are occurring.

10.2.4.1.8 Seasonally Flooded Agricultural Lands

Environmental measures for seasonally flooded agricultural lands are provided for the giant garter snake.

10.2.5 Environmental Consequences/Environmental Impacts of the No Action/No Project Alternative

The No Action/No Project alternative would involve not implementing EWA asset acquisition and management actions as described in Section 2.4.2. Under the No Action/No Project alternative there would be no new construction work by either the Project Agencies or project contractors to address the reduction in water supply that would result in a loss of vegetation or wildlife habitat. The No Action/No Project alternative would not alter (increase development or slowdown development) of the other agriculture, urban development, or land management projects that would affect vegetation and wildlife habitat.

As under the Baseline Condition, during some years, project contractors may not receive their full water allocations and would respond accordingly. Agricultural interests could fallow crops, substitute crops requiring less water, or pump groundwater as a substitute water supply. Municipal agencies could use alternative sources such groundwater, seek other surface water sources, or attempt additional water conservation measures. The effects of these water measures would be the same as under the Baseline Condition and thus there would be no effects to vegetation and wildlife in the Export Service area due to the No Action/No Project Alternative.

As a potential additional response to reduced water allocations, south of the Delta interests could also seek to obtain water from north of the Delta sellers using water transfer processes similar to those described for the EWA program. If the water transfers are similar to those described in Section 10.2.6, the effects of the transfers would be similar. Because transfers involving project facilities would require individual environmental documents, the effects would be disclosed through a separate environmental review process.

No effects to Delta vegetation and wildlife habitat would occur under the No Action/No Project alternative. No actions would be taken within the Delta that could affect vegetation and wildlife relative to the reduction in water allocation, other than those actions currently in the planning stages under the CALFED program.

Within the Export Service Area, North of Delta, and Delta areas, there are a number of urban, agricultural, and habitat restoration projects either planned or being implemented that could change Baseline Conditions during the next four years. Urban developments would reduce some wildlife habitat, agricultural land conversion could increase wildlife habitat, while mitigation programs and ERP-directed programs will increase habitat in general. These future restoration projects are also expected to increase the quality, distribution, and quantity of vegetation and wildlife habitats described in Section 10.1. The success of these projects during the Stage 1 phase of CALFED currently is not known. The EWA No Action/No Project alternative will not affect the current trend in changes in plant and animal habitats within the EWA area of analysis.

Future conditions also include habitat losses caused by other projects. Some of these losses are described in the Cumulative Effects section of this chapter. (See Section 10.2.11.) Additional losses that may occur during the five-year assessment period are not currently known.

10.2.6 Environmental Consequences/Environmental Impacts of the Flexible Purchase Alternative

During portions of the year, EWA actions could raise or lower reservoir levels and increase or decrease river flows compared to the Baseline Condition. The following section describes how these changes could affect vegetation and wildlife within each community.

Additionally, as stated in Section 10.1, numerous HCPs and NCCPs have been approved or are in-progress for areas throughout the State of California. A portion of these plans cover areas outside where EWA actions would take place. For those plans that cover areas where EWA actions would take place, such as the Placer County HCP/NCCP, EWA actions would not affect the species and communities covered by the plans. EWA water acquisition and transfer actions would not involve the construction of new facilities and crop idling effects would be temporary.

10.2.6.1 Upstream from the Delta

10.2.6.1.1 Valley Riverine Aquatic/Valley Riverine Riparian

This section analyzes the EWA water acquisition and management effects on aquatic habitat and associated riparian vegetation and associated wildlife within the valley reach of each river system in the Upstream from the Delta Region. Effects would be considered significant should 1) decreases in river flows or reservoir levels reduce the water source for riparian vegetation, thereby decreasing its extent; 2) decreases in stream flow do not allow for temporary flooding of adjacent floodplain thereby inhibiting germination and growth of seedlings; 3) decreases in river flows strand populations of wildlife species (e.g., tadpoles) increasing their loss through predation; 4) increases in stream flow cause erosion of stream banks resulting in a loss of shaded riverine habitat; 5) increases in stream flows flush populations (non-volitional movement) of wildlife from protected areas or wash seedlings of riparian vegetation away from stream banks/shallow areas causing a loss in recruitment vegetation; or 6) increases and timing of flows are such that natural geomorphic processes such as point bar formation do not occur and establishment of seedlings in adversely affected.

The timing and amount of EWA water releases, will, in general, decrease mean flow peaks in early spring and increase summer water levels available for plants. Peak spring flows typically clear the river channel of debris and unclog sediments, depositing them downstream creating point bars and nutrient rich floodplains essential for early successional plant germination. Decreasing summer water levels ensure that pioneer seedlings are able to match growth with increasingly unavailable water supplies and outcompete non-pioneer species for resources. Currently, river regulation in the Central Valley has created artificially stable hydrological conditions and EWA actions would further exacerbate this trend. Affects to riparian habitat

include the loss of point bars and other substrates for seed germination and increased water supply availability during the summer allowing non-pioneer species to compete for resources once only available to pioneer species.

Another consequence of altered hydrological conditions is the presence of amphibian species in river mainstems where they were previously confined to tributaries. Dams, particularly those created for power generation have often reduced flows to such a degree that newly created slow moving water habitats attract frogs such as the foothill yellow-legged frog (FYLF). These frogs lay eggs March through May, and the tadpoles metamorphose three to four months later. Frogs at this stage are highly vulnerable to non-volitional movements because of increased flows. However, a search of the CNDDB and current literature did not reveal any occurrences of species such as the FYLF in the mainstems of the rivers being affected by EWA actions.

The following sections provide detailed timing and flow rate discussions for each river and associated EWA actions. The effects on riparian habitats adjacent to each river and associated wildlife are the same as those just discussed, the only difference being the magnitude of the effect. The environmental measure outlined in Section 10.2.4 will ensure that effects on riparian habitat are avoided or minimized.

Sacramento River

EWA acquisition of Sacramento River contractor water via groundwater substitution and crop idling would decrease Sacramento River flows from Lake Shasta downstream to the point of diversion in June[7]*.* EWA acquisition of up to 120,000 acre-feet of water via groundwater substitution and up to 158,000 acre-feet from crop idling would decrease Sacramento River flows by 1,160 cfs in June. The reduction from 18,180 cfs to 17,020 cfs in June would not affect shoreline vegetation. Thus, the decrease in median monthly flows during June is less than significant.

EWA acquisition of Sacramento River contractor water via groundwater substitution and crop idling would change Sacramento River flows downstream from Lake Shasta in April through September. EWA acquisition of up to 120,000 acre-feet of water via groundwater substitution and up to 158,000 acre-feet from crop idling would increase Sacramento River flows by 240 cfs between Lake Shasta and the point of diversion in July. Flows in this reach would decrease 133 cfs and 111 cfs in August and September, respectively. Downstream from the diversion point, flows would increase by 289 cfs, 372 cfs, 429 cfs, 1,940 cfs, 777 cfs, and 157 cfs in April through September, respectively. This represents a 1 to 11 percent increase in flow and is not considered significant to cause adverse effects.

---

[7] Because of flow and temperature requirements in the Sacramento River, Lake Shasta would not be able to store EWA water from groundwater substitution and crop idling in April and May. During these months, flows in the Sacramento River would be the same as under the Baseline Condition. In some years, (depending on hydrologic conditions) Lake Shasta would store EWA water in June.

Feather River

EWA acquisition of Feather River contractor water via groundwater substitution, crop idling, and stored reservoir water would change Feather River flows downstream of Oroville Reservoir from July through September relative to the Baseline Condition. Under the Flexible Purchase Alternative, crop idling and groundwater substitution transfers would not affect flow in the lower Feather River from April through June (the hold-back period) because this water would typically have been released from the Thermalito Afterbay directly to the water agencies. Crop idling and groundwater substitution transfers would act in conjunction with Oroville-Wyandotte ID stored reservoir water transfers to increase flows in the lower Feather River from July through September. Long-term average flows in the lower Feather River below Oroville Dam during the March through October growing season would increase 2105 cfs (from 5, 896 cfs to 6,497 cfs) in July, increase 850 cfs (from 4,434 cfs to 4,515 cfs) in August, and increase 149 cfs (from 1,600 cfs to 1,421 cfs) in September compared to the Baseline Condition. These changes represent a 36 percent increase in July, a 19 percent increase in August, and a 9 percent increase in September. EWA agencies would monitor the releases to ensure that adverse effects do not occur, and institute changes to quantities of water released through adaptive management processes to avoid or minimize any adverse effect.

Yuba River

EWA acquisition of Yuba County WA water via groundwater substitution would decrease Yuba River flows from the power facility discharge upstream from Englebright Dam to the users' diversion points, typically at Englebright and Daguerre Point Dams, from April to June. Yuba River flows would decrease at most by 239 cfs in late spring as farmers use groundwater for irrigation instead of surface water from New Bullards Bar Reservoir. (A total of 12 to 19 percent reduction in April through June compared to the median flow under the Baseline Condition.) EWA agencies would monitor the releases to ensure that adverse effects do not occur, and institute changes to quantities of water released through adaptive management processes to avoid or minimize any adverse effect.

EWA acquisition of Yuba County WA water via stored reservoir water and groundwater substitution would increase Yuba River flows from July through September. EWA agencies acquisition of Yuba County WA stored reservoir water and Yuba River contractor water via groundwater substitution would increase Yuba River flows, downstream of Englebright Dam, from July to September relative to the Baseline Condition. Flows would increase at most by 1,005 cfs in July through September, approximately 60 percent above the Baseline Condition. While this increase would be a noticeable change, releases would be operated to maintain relatively constant flows during this time period in accordance with existing Yuba County WA operations to protect fish and the environment. This increase in flow would have the potential to increase non-volitional movement of aquatic wildlife that cannot find quieter water to remain in during periods of increase. However, species such as the California red-legged frog and foothill yellow-legged frog are not known to inhabit this reach of the Yuba River. These effects cannot be quantified, but may be considered significant adverse effects if

the EWA-related water releases are maintained at significantly higher flows for long periods of time. EWA agencies would monitor the releases to ensure that adverse effects do not occur, and institute changes to quantities of water released through adaptive management processes to avoid or minimize any adverse effect.

American River

EWA acquisition of Placer County WA stored reservoir water would decrease flows in the American River compared to the Baseline Condition while the reservoir refills during winter months. During the rainy season after December, Placer County WA would refill its reservoirs, which would decrease the flow that travels downstream of French Meadows, and Hell Hole Reservoirs. These decreases would occur during the winter rainy season, and would not likely have an effect on flow downstream of Folsom Lake.

EWA acquisition of Sacramento Groundwater Authority water via groundwater substitution and Placer County WA stored reservoir water under the Flexible Purchase Alternative would increase flows in the Lower American River compared to baseline from June to December. American River flows would increase from June through December because of increased releases from Folsom Lake because of Sacramento Groundwater Authority groundwater purchase transfers and Placer County WA stored reservoir water. The change in flow is not predicted to adversely affect stream habitat.

Merced and San Joaquin Rivers

EWA acquisition of Merced ID water via groundwater substitution would increase Merced River fall flows relative to the Baseline Condition. EWA agency acquisition of Merced ID water via groundwater substitution would increase Merced River flows by a maximum of 210 cfs (from 231 to 441 cfs; 52 percent above the median) below Crocker-Huffman Dam in the fall relative to the Baseline Condition as the water is released from Lake McClure. EWA agencies would monitor the releases to ensure that adverse effects do not occur, and institute changes to quantities of water released through adaptive management processes to avoid or minimize any adverse effect.

10.2.6.1.2 Montane Riverine Aquatic/Montane Riparian Habitat

The EWA program could affect Montane Riverine Aquatic habitats that are on the same rivers as the Valley Riverine Aquatic habitats, but at higher elevations. Several of the following sections include abbreviated discussions from the Valley Riverine Aquatic habitat evaluation.

Sacramento River

Montane Riverine Aquatic habitat within the EWA area of analysis on the Sacramento River occurs between approximately Red Bluff, CA and Lake Shasta.

EWA acquisition of Sacramento River contractor water via groundwater substitution and crop idling under the Flexible Purchase Alternative would change Sacramento River flows from June through September. The flow changes would be the same as those described in Section 10.2.6.1.1 for Valley Riverine Aquatic habitat. The numbers represent a 1 to 11

percent increase in flow. No adverse effect to habitat is predicted due to the low changes in flow.

Feather River

EWA acquisition of Oroville-Wyandotte ID stored reservoir water would increase Feather River flows below Sly Creek and Little Grass Valley Reservoirs to Lake Oroville in November and December. The water released from Little Grass Valley and Sly Creek Reservoirs into Lake Oroville would get diverted through Woodleaf and Forbestown tunnels to run through the corresponding power generation facilities and end up in Ponderosa Reservoir. Transfer water spills from Ponderosa Reservoir directly into Lake Oroville. Because the water transferred from Little Grass Valley and Sly Creek Reservoirs into Lake Oroville would almost entirely bypass the Feather River, there would be no effects on vegetation and wildlife.

EWA acquisition of Oroville-Wyandotte ID stored reservoir water could decrease flows in the South Fork of the Feather River during the winter. Oroville-Wyandotte ID would deliver stored reservoir water for the EWA agencies from October through December, and store it in Lake Oroville until it could be transferred through the Delta during the following summer. During the rainy season after December, Oroville-Wyandotte ID would refill its reservoirs, which would decrease the flow that travels downstream of Sly Creek and Little Grass Valley Reservoirs. The effect is not considered significant because it does not occur during the growing season for vegetation along the river.

Yuba River

Montane Riverine Aquatic habitat occurs on the Yuba River between approximately Timbuctoo Bend and New Bullards Bar Reservoir.

EWA acquisition of Yuba County WA water via stored reservoir water and groundwater substitution would decrease Yuba River flows downstream of New Bullards Bar Reservoir from April to June and increase flows from July through September. The flow changes would be the same as those described in Section 10.2.6.1.1 for Valley Riverine Aquatic habitat. The only stretch of the river that includes Montane Riverine Aquatic habitat is from Englebright Dam downstream to Timbuctoo Bend (between Englebright and Daguerre Point Dams). The increases from July through September would noticeably change river flows. The Yuba County WA would operate the system to maintain relatively constant flows during this time period in accordance with existing Yuba County WA operations to protect fish and the environment.

American River

EWA acquisition of Placer County WA stored reservoir water from French Meadows and Hell Hole Reservoirs would increase flows in the Middle Fork of the American River compared to the baseline downstream from Oxbow Power House to Folsom Lake from June to October. At a maximum, releases would increase flows from June through August relative to the Baseline Condition. Median flows downstream from Oxbow Power House (where the reservoirs' power facilities release water into the river) on the Middle Fork are 790, 793, and 776 cfs during June, July, and August, respectively. EWA agencies would monitor the releases to ensure that adverse effects do not occur, and institute

changes to quantities of water released through adaptive management processes to avoid or minimize any adverse effect.

EWA acquisition of Placer County WA stored reservoir water would decrease flows in the Middle Fork of the American River compared to the Baseline Condition while the reservoir refills during winter months. During the rainy season after December, Placer County WA would refill its reservoirs, which would decrease the flow that travels downstream of Oxbow Power House. These decreases would occur during the winter rainy season, and would likely not substantially decrease flows in the river.

EWA acquisition of Placer County WA stored reservoir water would decrease flows in the Middle Fork of the American River compared to the Baseline Condition while the reservoir refills during winter months. During the rainy season after December, Placer County WA would refill its reservoirs, which would decrease the flow that travels downstream of French Meadows, and Hell Hole Reservoirs.

Merced River

Montane Riverine Aquatic habitat occurs on the Merced River between approximately Merced Falls and Lake McClure.

EWA acquisition of Merced ID water via groundwater substitution would decrease Merced River summer flows and increase Merced River fall flows relative to the Baseline Condition. Merced ID would hold the EWA transfer water in Lake McClure until the fall, when it would release the water downstream. This pattern would decrease flows downstream of New Exchequer Dam in the summer by a maximum of 70 cfs, but only for the short distance between New Exchequer Dam and Lake McSwain (the typical diversion point). EWA agency acquisition of Merced ID water via groundwater substitution would increase Merced River flows in fall relative to the Baseline Condition as the water is released from Lake McClure. EWA agencies would monitor the releases to ensure that adverse effects do not occur, and institute changes to quantities of water released through adaptive management processes to avoid or minimize any adverse effect.

10.2.6.1.3 Lacustrine

Comparing EWA actions to the Baseline Condition determines project effects. Reservoirs fluctuate seasonally in response to use and hydrology; therefore, this normal fluctuation creates the Baseline Condition. EWA actions further modify these fluctuations, sometimes accentuating changes and other times attenuating changes in reservoir levels. Any change in reservoir level that could reduce the extent of riparian vegetation along the shore of the reservoir or populations of species inhabiting the shoreline environment would be significant. Chapter 9 presents the analyses of effects to fish populations inhabiting reservoir being used to store and manage EWA assets.

Sacramento River

EWA acquisition of Sacramento River contractor water via groundwater substitution and crop idling would change the timing of releases from Lake Shasta. Lake Shasta would hold back at most 68,900 acre-feet that would have been released under the Baseline Condition.

The lake level would decline faster in July and August compared to the Baseline Condition; however, end of month elevation in September would be the same as the Baseline Condition because of reduced releases during September. (See Figure 14-5.) Lake Shasta elevation would be 1.1 feet lower in July, 0.5 of a foot lower in August, and equal to the Baseline Condition in September. These small changes of less than 0.5 inches per day would not be enough to affect the lacustrine habitat within the lake or surrounding the lake perimeter. The water source for riparian vegetation will not be affected and the upland scrub vegetation surrounding the reservoir does not rely on the reservoir for its water source. Therefore, the change in Lake Shasta water surface elevation would have a less-than-significant effect on the lacustrine habitat used by special-status species or other wildlife, particularly as wildlife movement corridors or nurseries along the water edge.

Feather River

EWA acquisition of Oroville-Wyandotte ID stored reservoir water would decrease surface water elevations from December until refill for Sly Creek and Little Grass Valley Reservoirs. Little Grass Valley and Sly Creek Reservoirs could release a combined maximum of 15,000 acre-feet of water from October to December (a maximum of 12,000 acre-feet from Little Grass Valley and a maximum of 5,000 acre-feet from Sly Creek Reservoir). Reservoir levels within Little Grass Valley would decrease approximately 12 feet because of the maximum potential release. Reservoir levels within Sly Creek Reservoir would decrease approximately 17 feet because of the maximum potential release. These reductions would not affect shoreline vegetation because this vegetation is not dependent upon reservoir levels for water (the shore-line vegetation is not riparian, it is associated with upland scrub that is not dependent on saturated soil for water). In addition, Sly Creek and Little Grass Valley reservoir water levels fluctuate seasonally and annually; therefore, the drawdown zone is vegetated primarily with non-native herbaceous plants and scattered willow shrubs that do not form a contiguous riparian community and would not be affected by decreases in reservoir levels caused by EWA actions (CALFED 1998). Therefore, the EWA agencies' acquisition of Oroville-Wyandotte ID stored reservoir water would have a less-than-significant effect on the lacustrine habitat of Sly Creek and Little Grass Valley reservoirs used by special-status species or other wildlife, particularly as wildlife movement corridors or nurseries.

EWA acquisition of Feather River contractor water via crop idling and groundwater substitution would increase the surface water elevation April to June and decrease the surface water elevation in July and August in Lake Oroville compared to the Baseline Condition. EWA agencies would acquire 110,000 acre-feet through groundwater substitution and 126,550 acre-feet through crop idling. During April through June, Lake Oroville would hold back water that would have been released under the Baseline Condition. By the end of June, the surface water elevation in the reservoir would be, at most, two feet higher than under Baseline Conditions. (See Figure 14-8.) Increased releases in July and August as the stored EWA water is released for cross-Delta transfer would cause the lake level to decline faster compared to Baseline Conditions; however, reduced releases in September would allow end of month elevation in September to

be the same as Baseline Conditions. The increase water surface elevation would result in increased flooding of shoreline habitat. The increased level would come slowly (less than an inch per day) so that wildlife would not be affected and riparian vegetation are accustomed to flooding and will not be adversely affected. Therefore, the change in Lake Oroville water surface elevation would have less-than-significant effects on the lacustrine habitat used by special-status species or other wildlife, particularly as wildlife movement corridors or nurseries along the shoreline.

Yuba River

EWA acquisition of water from Yuba County Water Agency (Yuba County WA) via stored reservoir water and groundwater substitution would alter the surface water elevation April to refill at New Bullards Bar Reservoir. EWA agencies would acquire 85,000 acre-feet through groundwater substitution. During April through June, New Bullards Bar Reservoir would hold back water that would have been released under the Baseline Condition. By the end of June, the surface water elevation in the reservoir would be, at most, 5 feet higher than under the Baseline Condition. (See Figure 14-9.) An increase in the surface water elevation would only inundate the existing drawdown zone and would not affect vegetation and wildlife.

Yuba County WA would not enter into a transfer agreement unless local needs, instream flows, and system demand requirements were met. If these elements were met, EWA agencies could acquire water during July through September. Releases from New Bullards Bar Reservoir would be, at a maximum, 100,000 acre-feet of water from stored reservoir water and 85,000 acre-feet from groundwater substitution. The combination of these releases would reduce lake levels compared to the Baseline Condition by 1 foot, 10 feet, and 24 feet in July, August, and September, respectively. This reduction would not affect shoreline vegetation because this vegetation is not dependent upon reservoir levels for water (the shorel;ine vegetation is not riparian, it is associated with upland scrub that is not dependent on saturated soil for water). In addition, New Bullards Bar Reservoir water levels fluctuate seasonally and annually; therefore, the drawdown zone is vegetated primarily with non-native herbaceous plants and scattered willow shrubs that do not form contiguous riparian communities and would not be affected by decreases in water levels caused by EWA actions (CALFED 1998). Therefore, the EWA agency acquisition of Yuba County Water Agency water would have less-than-significant effects on the lacustrine habitat of New Bullards Bar Reservoir used by special-status species or other wildlife, particularly as wildlife movement corridors or nurseries along the shoreline.

The EWA agencies and Yuba County WA could agree to transfer water under a multi-year contract. If full refill occurred, which it has for 85 percent of the past transfers, effects on vegetation and wildlife for subsequent years would be the same as described above. If full refill did not occur, Yuba County WA would consider selling less water the following year.

American River

EWA acquisition of Placer County Water Agency stored reservoir water would decrease surface water elevations June to refill at Hell Hole and/or French Meadows Reservoirs. Hell

Hole Reservoir and French Meadows Reservoir would release a combined maximum of 20,000 acre-feet of water. The amount released from each reservoir would be at the discretion of Placer County Water Agency; however, this analysis assumes that releases would be in proportion to the sizes of the reservoirs (61 percent from Hell Hole, the remainder from French Meadows). Releases of reservoir water from French Meadows and Hell Hole could begin as early as June and end as late as October. For the purposes of this analysis, releases were assumed to take place between July and September. Using these assumptions, French Meadows would release 7,800 acre-feet, decreasing water surface levels by approximately eight feet. Hell Hole would release 12,200 acre-feet decreasing water surface levels by 14 feet. These reductions would not affect shoreline vegetation because this vegetation is not dependent upon reservoir levels for water. In addition, French Meadows and Hell Hole Reservoir water levels fluctuate seasonally and annually; therefore, the drawdown zones are vegetated primarily with non-native herbaceous plants and scattered willow shrubs that do not form a contiguous riparian community and would not be affected by decreases in reservoir levels caused by EWA actions (CALFED 1998). Therefore, the EWA agency acquisition of stored reservoir water and the decrease in surface water elevations at French Meadows and Hell Hole Reservoirs would have a less-than-significant effect on lacustrine habitat used by special-status species or other wildlife, particularly as wildlife movement corridors or nurseries along the shoreline.

EWA acquisition of Sacramento Groundwater Authority's water via stored groundwater purchase and Placer County WA's water via stored reservoir water would change surface water elevations in Folsom Lake. During July and August, the surface water elevation at Folsom Lake would be 0.8 of a foot lower than the Baseline Condition. The lake level would decline faster in July and August compared to the Baseline Condition; however, end of month elevation in September would be the same as the Baseline Condition because of reduced releases during September. (See Figure 14-12.) Therefore, the change in Folsom Lake surface water elevations would have less-than-significant effects on lacustrine habitat used by special-status species or other wildlife, particularly as wildlife movement corridors or nurseries.

Merced River

EWA acquisition of Merced ID water via groundwater substitution would increase the water surface elevation in Lake McClure compared to the Baseline Condition. EWA agencies could acquire 25,000 acre-feet through groundwater substitution. During April through September, Lake McClure would hold back water that would have been released under the Baseline Condition. By the end of September, the surface water elevation in the reservoir would be, at most, three feet higher than under Baseline Conditions. (See Figure 14-13.) This increase would occur slowly over the six-month period, less than 0.5 inches per day. The increase would not flood sensitive habitats or nesting areas. Therefore, the change in Lake McClure surface water elevations would have a less-than-significant effect on lacustrine habitat used by special-status species or other wildlife, particularly as wildlife movement corridors or nurseries along the shoreline.

10.2.6.1.4 Nontidal Freshwater Permanent Emergent

EWA acquisition of water via groundwater substitution transfers in the Upstream from the Delta Region could lower groundwater levels. As a part of groundwater substitution transfers, the willing sellers would pump additional groundwater resulting in a decreased use of surface water. Pumping additional groundwater would decrease groundwater levels in the vicinity of the sellers' pumps. Some areas of Nontidal Freshwater Permanent Emergent habitat have groundwater as a source of water, and decreasing groundwater levels could reduce the supplies for these habitats thereby drying up the habitat.

Chapter 6, Groundwater Resources, analyzes in detail how groundwater substitution transfers could affect groundwater levels and surrounding beneficial users, including the environment. The section concludes that these effects could be potentially significant, and requires several measures. These measures would require monitoring to identify if any effects are occurring, and implementation of additional mitigation by the seller if any effects should occur. The additional mitigation steps could be cessation of pumping or use of a replacement water source for the affected area. Because the mitigation involves monitoring and the effect may only be determined after the drying of a habitat is observed, groundwater substitution has the potential for a significant effect on nontidal permanent emergent wetlands. The degree of that effect will be dependent on how soon the effect is noted and the response by the willing seller to mitigate that effect. Implementation of Environmental Measures in Section 10.2.4 will reduce this effect to a less-than-significant level.

10.2.6.1.5 Natural Seasonal Wetland

EWA acquisition of water via groundwater substitution transfers in the Upstream from the Delta Region could lower groundwater levels. As a part of groundwater substitution transfers, the willing sellers would use groundwater to irrigate crops and decrease use of surface water. Pumping additional groundwater would decrease groundwater levels in the vicinity of the sellers' pumps. Some areas of Natural Seasonal Wetland habitat have groundwater as a source of water, and decreasing groundwater levels could reduce the water base for these habitats.

Chapter 6, Groundwater Resources, analyzes in detail how groundwater substitution transfers could affect groundwater levels and surrounding beneficial users, including the environment. The section concludes that these effects could be potentially significant, and requires several measures. These measures would require monitoring to identify if any effects are occurring, and implementation of additional measures by the seller if any effects should occur. The additional mitigation steps could be cessation of pumping or use of a replacement water source for the affected area. Because the mitigation involves monitoring and the effect may only be determined after the drying of a habitat is observed, groundwater substitution has the potential for a significant effect on natural seasonal wetlands. The degree of that effect will be

dependent on how soon the effect is noted and the response by the willing seller to mitigate that effect. Implementation of Environmental Measures in Section 10.2.4 will reduce this effect to a less-than-significant level.

10.2.6.1.6 Managed Seasonal Wetland

Groundwater substitution and crop idling actions could have adverse effects on managed seasonal wetlands by reducing the water supply to these areas. The project effects on managed seasonal wetlands would be the same as for the nontidal emergent and natural seasonal wetland communities due to their potential association with high groundwater tables. The groundwater substitution mitigation strategy would also apply to this community. Effects to the community would be considered significant if the willing seller does not mitigate for the loss of the water source for this community.

In addition, both groundwater substitution and crop idling actions could result in less water in agriculture supply and return flow ditches, potentially resulting in the desiccation of managed seasonal wetlands. The sections below analyze potential project effects on agricultural water supplies caused by these two EWA actions.

Groundwater Substitution Transfers in the Sacramento Valley

Groundwater substitution transfers would decrease flows in agricultural delivery ditches. When water agencies agree to sell water to the EWA agencies through groundwater substitution transfers, the water agencies will identify the specific farms within each area participating in the idling action. The water sellers then forgo their surface water supplies and substitute water supplies with groundwater. This change results in less diversion into the agricultural delivery system, which could affect species within the delivery ditches. This decrease is likely to adversely affect the species and vegetation that depend on this flow; therefore, this effect is potentially significant. Measures in Section 10.2.4 would reduce effects to a less-than-significant level.

Crop Idling Transfers

The effects of crop idling transfers on managed seasonal wetlands depend on the location of the transfers. The following section is divided by river system to fully explain these potential effects.

EWA acquisition of Sacramento River water via crop idling would reduce the water supply for managed seasonal wetlands that rely on return flows from fields that would be idled. Glenn, Colusa, and Yolo Counties could idle up to 47,980 acres. The EWA agencies would purchase approximately 3.3 acre-feet per acre (the amount of water consumed by the crop); however, under the Baseline Condition, water agencies divert additional water from the Sacramento River to account for system losses. System losses include conveyance losses (evaporation or percolation within the conveyance system), riparian evapotranspiration (water used by vegetation along the conveyance system), and on-farm losses (deep percolation to groundwater or tailwater runoff). The amount of water diverted varies depending on the amount of system losses.

If farmers idled their crops, their water agency would reduce diversions by the 3.3 acre-feet per acre plus the additional amount that goes to on-farm losses. Of this additional amount that is applied to fields in the Baseline Condition, a portion percolates into the groundwater aquifer below and a portion runs off the field back into the conveyance system. This "tailwater" that runs back into the conveyance

system could then be used again by managed wetlands downstream on the conveyance system. If farmers idled land, tailwater would no longer be available to downstream users, either other farmers or managed wetlands.

Few managed seasonal wetlands exist downstream of the water agencies that may sell water to the EWA agencies via crop idling. The effects on these wetlands because of the reduction of return flows, however, could be potentially significant. The environmental measures in Section 10.2.4 would reduce effects to managed seasonal wetlands to a less-than-significant level.

EWA acquisition of Feather River water via crop idling would reduce the water supply for managed seasonal wetlands that rely on the return flows from fields that would be idled. Butte and Sutter Counties could idle up to 38, 340 acres. As described above for the Sacramento River, idling these fields would reduce tailwater, which could reduce supplies to downstream wetlands. Several of the agencies within Butte and Sutter Counties discharge return flows from the irrigation systems into Butte Creek, which provides water for several managed seasonal wetlands. The reduction in return flows could have potentially significant effects on these managed seasonal wetlands. The environmental measures in Section 10.2.4 would reduce effects to managed seasonal wetlands to a less-than-significant level.

EWA acquisition of American River water via crop idling would reduce the water supply for managed seasonal wetlands that rely on return flows from fields that would be idled. Placer County could idle up to 3,280 acres. As described above for the Sacramento River, idling these fields would reduce tailwater, which could reduce supplies to downstream wetlands. The reduction in return flows could have potentially significant effects on managed seasonal wetlands. The environmental measures in Section 10.2.4 would reduce effects to managed seasonal wetlands to a less-than-significant level.

10.2.6.1.7 Seasonally Flooded Agriculture

Crop idling would reduce the rice acreage in the Sacramento Valley. Table 10-4 displays SFA acreage and waste grain reduction for the maximum acreage of crop idling anticipated for all counties where idling action could occur for the EWA program. These numbers reflect the maximum water transfers (for all water programs acquiring water through crop idling) based on the project limitation of 20 percent maximum crop acreage idled per county. Idling this acreage would reduce the extent of habitat available to those special-status species dependent upon SFA for some portion of their lifecycle (identified with an * in Table 10-3), which would result in potentially significant effects to those species. Section 10.2.4 proposes environmental measures to help minimize any adverse effects to special-status species.

Table 10-4 also displays the reduction in the availability of waste grain as forage to wildlife by county and total for all crop idling actions (depending on agricultural practices). This amount would result in a potentially significant effect to those special-status species dependent upon waste grain for a large portion of their forage

(identified with an * in Table 10-3). Section 10.2.4 proposes environmental measures to help minimize any adverse effects to special-status species.

Associated with the idling of SFA is the potential loss of water within adjacent irrigation and return ditches in all six counties. EWA water would not enter water agencies' distribution systems because it is no longer being delivered to the agricultural users, and unused flows from the fields would not return to the delivery system. These changes have the potential to reduce flow in these ditches, thereby reducing the value of habitat provided. Some irrigation ditches provide forage, resting, and nesting habitat and serve as migration corridors. Devaluing or losing this habitat could affect giant garter snakes, herons, egrets, western pond turtles, etc. This decrease to water in agricultural ditches is a potentially significant effect to these special-status species. Section 10.2.4 proposes environmental measures to help minimize any adverse effects to special-status species.

Table 10-4
Seasonally Flooded Agriculture Acreage and Waste Grain Reductions in Each County Based on Crop Idling Maximum Purchases under the Flexible Purchase Alternative

	Rice Acreage (97 Ag Census) (AC)	Maximum Idled Acreage (AC)	Maximum Percent Rice Acreage (%)	Waste Grain per Acre (lbs)	Total Waste Grain (million lbs)	Maximum Waste Grain Loss (million lbs)	Maximum Percent Waste Grain Loss (%)	Maximum Total Acre-Feet of Water Available for EWA Fish Actions (TAF)	Maximum Potential Square Miles Idled
Butte	95,120	19,000	20%	350	33.3	6.6	20%	62.7	30
Colusa	132,338	26,460	20%	350	46.3	9.2	20%	87.3	41
Glenn	83,777	16,750	20%	350	29.3	5.7	20%	55.2	26
Placer	16,379	3,280	20%	350	5.7	1.1	20%	10.8	5
Sutter	96,722	19,340	20%	350	33.9	6.8	20%	63.8	30
Yolo	23,822	4,770	20%	350	8.3	1.7	20%	15.7	7
Total	448,158	89,608	20%	350	156.9	31.1	20%	295.7	140

Associated with the idling of SFA is the potential for fragmentation of seasonally flooded agriculture land habitat. Assuming the maximum acreage is idled (20 percent of rice within each county), a total of 140 square miles of formerly flooded land would be dry in all six counties over the late spring, summer, and early fall months. This impact would be significant if it occurred as one contiguous block of SFA. The idled land would have the potential to interfere with wildlife migration and the dispersal of individuals within a metapopulation (hence a loss of genetic diversity). The inability of a snake to migrate to more suitable habitat would potentially be a significant effect to this special-status species, especially those populations that are succumbing to other population pressures. Section 10.2.4 identifies environmental measures intended to reduce the significant effects to species utilizing SFA for an important part of their life cycle.

Also associated with idling SFA is the potential to affect wildlife, in particular special-status species. The following text provides a summary of the special-status species assessment conducted in the EWA ASIP. Table 10-5 provides the relationship of special-status species associated with rice lands and the rice production cycle.

10.2.6.1.8 Aleutian Canada Goose

Aleutian Canada Goose Effects Statement: Crop idling would reduce the SFA acreage in the Sacramento Valley reducing winter forage and habitat for this recovering species. The Aleutian Canada goose is a winter visitor to the Central Valley. The primary cause of its population decline was the introduction of foxes to its breeding islands in Alaska. A recovery plan (USFWS 1991a) has been put in place to address the threat predators pose to its breeding habitat. The concern for its winter use in California is to ensure the survival of the over wintering populations as measure of addressing the species overall recovery.

Like many migratory waterfowl, the Aleutian Canada goose forages on waste grain on agricultural fields in the Colusa Basin. This includes flooded rice land and rice land stubble. In addition to waste grains, the birds also consume insects and vegetative matter.

The concern for SFA idling is a reduced winter food supply for the Aleutian Canada goose. However, the analysis of waterfowl population trends for the Central Valley (Figure 10-4) shows no correlation between the amount of waste grain and waterfowl numbers. It appears that waste grain is not a limiting factor for controlling waterfowl populations and therefore the reductions of winter forage resulting from EWA crop idling would have a less-than-significant effect on the species. No environmental measure for the Aleutian Canada goose related to reduction in winter forage is proposed.

Crop idling actions taken by EWA agencies would have less-than-significant effects on the Aleutian Canada goose.

10.2.6.1.9 Black Tern

Black Tern Effects Statement: Crop idling would reduce the SFA acreage in the Sacramento Valley reducing breeding habitat and summer habitat for this special status species. The black tern was once a common spring and summer visitor to the emergent wetlands of the Central Valley, but its numbers have declined due to habitat losses. Although restricted to freshwater habitats for breeding, it migrates to bays, rivers, and pelagic waters the remainder of the year. SFA habitat has partially replaced the lost emergent vegetation breeding habitat for this species. The rice production cycle coincides with the tern's seasonal behavior in two ways: 1) fields are flooded during the tern's Central Valley breeding season, and 2) fields are dry when the birds have migrated to other aquatic habitats.

Remain in drainages and canals with emergent vegetation until hibernation. Canals have concentrated prey to prepare for hibernation.	Turtles are dormant.	Turtles are dormant.

* The determination of when field preparation initiates is dependent on the last significant rainfall. If rainfall ends in March, field prep can start in April, if rain extends into May, field preparation may wait until early June..

The black tern forages by hovering above wet meadows and emergent wetlands, catching insects in the air and diving into the water to capture tadpoles, crayfish, small fish, and mollusks. It nests in loose mats of dead vegetation on the ground or anchored to other vegetation. In rice fields, the tern can also nest on dikes that separate the fields.

Because this species uses SFA for nesting and forage, a reduction of rice habitat could be detrimental to local populations. As an environmental measure, idling of rice habitat known to support colonies of black terns should be avoided. The EWA agencies will review maps of areas proposed for EWA water acquisition crop idling for the presence of the nearest colony. Fields supporting colonies will not be idled. The environmental measures in Section 10.2.4 would reduce effects on the black tern to less than significant.

10.2.6.1.10 Black-Crowned Night Heron

Black-Crowned Night Heron Effects Statement: Crop idling would reduce the SFA acreage in the Sacramento Valley affecting roosting habit and reducing forage for this special status species. The black-crowned night heron is a fairly common, yearlong resident of lowlands and foothills in California. It nests and roosts in dense tree foliage. Nesting roosts are typically near water, but non-breeding roosts can be some distance from water. Unlike other herons, the black-crowned night heron feeds primarily at night. It has a highly variable diet consisting of fish, crustaceans, aquatic insects, and other invertebrates, amphibians, and small mammals. There are reports of black-crowned night herons raiding bird colonies, including terns and tricolored black birds.

SFA habitat is just one of the many habitats used by the black-crowned night heron. These birds commonly fly up to three miles from their roosts to their feeding areas. Although idling of rice fields may reduce some forage available to the heron, the heron has no particular affinity to this habitat. The only effect would be to those herons, which have incorporated rice into their foraging routine. If insufficient forage is present within idled rice fields, the black-crowned night heron has the ability to forage elsewhere. The heron's roosting sites are not dependent on rice farmland practices and will not be affected by crop idling actions. The EWA program would have a less than significant effect on the black-crowned night heron.

10.2.6.1.11 Great Blue Heron, Great Egret, Snowy Egret

Great Blue Heron, Great Egret, Snowy Egret Effects Statement: Crop idling would reduce the SFA acreage in the Sacramento Valley affecting roosting habit and reducing forage for these special status species. These three species are included in one assessment because of coinciding roosting and feeding habits. In the Central Valley, all three species roost communally in trees in riparian areas, and feed commonly in shallow water, along shorelines, irrigation ditches, and other water bodies that contain fish, amphibians, insects, crustaceans, small mammals, and similar prey items. The species will readily abandon nesting attempts if disturbed. Destruction of riparian habitat and roosting trees is therefore a major concern for all of these species.

These species typically "commute" daily from their overnight roosting sites to their feeding areas. All species typically travel from one to five miles from the roosting site to the feeding locations. For seasonally flooded agricultural land (rice farmland), these species utilize both the rice fields and associated irrigation ditches. In relation to the rice cycle, the flooded fields during the summer and the irrigation ditches during the fall provide ample aquatic and insect prey. (See Section 10.1.1.14.) The dry fields during fall and spring, and partially flooded fields during the winter provide for some insect prey. None of the species rely on waste grain (except for the insect populations the grain may support) and thus absence of waste grain is not a concern for the species as it is for other avian species.

Idling of rice farmland for a season has the potential to reduce some summer and fall forage for egrets and herons that roost within 5 miles of the idling action. Because the birds will travel long distances to forage and because environmental measures for the giant garter snake will provide for the maintenance of aquatic habitat in rice growing areas, the only effect on these species is a potential change in forage patterns from idled fields to fields with abundant prey. Idling of rice farmland will not affect roosting sites; there is less human activity because no farming is occurring. Therefore, effects would be less than significant and no environmental measures are proposed.

10.2.6.1.12 Greater Sandhill Crane

Greater Sandhill Crane Effects Statement: Crop idling would reduce the SFA acreage in the Sacramento Valley thereby reducing winter forage for this special status species. The Central Valley Population of the sandhill crane is one of five populations in North America (Littlefield et al. 1994). It is comprised of 6000-6800 individuals, among which 3400 breed in the southern segment of its range, which includes northeast California, outside of the EWA area of analysis. The entire population winters in the Central Valley (Littlefield and Thompson 1979), and from 1983-1984, 95percent wintered from Sacramento Valley south to the Bay-Delta (Pogson and Lindstedt 1991).

The greater sandhill crane uses harvested rice fields in the Sacramento Valley for wintering habitat and forage from October to February (Littlefield 1993). It also uses grain fields in the Delta. The time period that cranes over winter also corresponds to the time when rice land is being harvested (October) and then becomes inactive. The greater sandhill crane prefers rice stubble that has not been flooded to decompose the vegetative materials. Burning or flooding to manage harvested rice stubble has contributed to the reduction of portions of the crane's wintering habitat (Littlefield 1993).

The greater sandhill crane typically returns to the same location each year to winter. Crop idling of seasonally flooded agricultural land used for rice production in the areas to which the cranes return will affect their wintering distribution patterns due to reduced forage on the idled fields. Although the cranes will disperse from their core areas as winter food resources diminish, crop idling could affect this change earlier. Avoiding crop idling in the core areas could minimize this effect to crane populations. Environmental measures in Section 10.2.4 would reduce this effect to a less-than-significant level.

10.2.6.1.13 Long-billed Curlew

Long-billed Curlew Effects Statement: Crop idling would reduce the SFA acreage in the Sacramento Valley reducing winter forage for this special status species. The long-billed curlew is a common winter visitor to the Central Valley where it forages on upland herbaceous plants and croplands. Some non-breeding individuals remain in the Central Valley during the summer. Breeding habitat is located in upland prairie grassland habitat outside of the EWA area of analysis. Winter migrants can arrive as early as June and most leave the valley by April. The primary food prey items of the curlew in the Central Valley are estuarine fish, insects, worms, spiders, crayfish, snails, and small crustaceans. Curlews "display no consistent season-specific food item preferences or limitations" (NRCS 2000). Therefore, during the winter curlews would take advantage of flooded or dry rice fields as long as adequate prey is available. The idling of seasonally flooded agricultural land would reduce some insect forage areas for the species (assuming the idled cropland produces less insects), but curlews would respond by looking for forage in other habitats. This effect is considered less than significant and no environmental measure is proposed for this species.

10.2.6.1.14 Tricolored Blackbird

Tricolored Blackbird Effects Statement: Crop idling would reduce the SFA acreage in the Sacramento Valley reducing summer forage and breeding colonies for this special status species. The tricolored blackbird is an inhabitant of the Sacramento-San Joaquin Delta and central coast of California in the winter and typically migrates to breeding locations near open freshwater in Sacramento County and throughout the San Joaquin Valley in the spring (Dehaven et al. 1975). In addition to insects and seeds, the tricolored blackbird forages on cultivated grains such as rice on croplands and flooded fields, and waste grain rice following the harvest (Zeiner et al. 1990). One study showed that rice constituted up to 38 percent of the annual diet of tricolored blackbirds (Crase and DeHaven 1978), but most reports indicate that insects can make up to 90 percent of their diets in the summer shifting to 88 percent vegetative matter in the winter.

Tricolored blackbirds generally breed from March to July, but have been observed breeding in the Sacramento Valley in October and December. In some years there may be up to three attempts at breeding, particularly if a colony is disturbed during an earlier attempt. Although the primary cause for the overall decline in tricolored blackbird populations is due to loss of wetland habitat to agriculture and urban development, the current threat to the population is predation by mammalian and avian predators and the destruction/disturbance of breeding colonies. Tricolored blackbirds can breed in large colonies, with over 100,000 birds being reported for some colonies.

Tricolored blackbirds have three basic requirements for selecting breeding colony sites (Beedy and Hamilton, 1997): 1) open accessible water; 2) protected nesting substrate, usually either flooded or thorny or spiny vegetation; and 3) suitable foraging space providing adequate insect prey within a few kilometers of the nesting colony. Rice fields can provide two of the three requirements (water and insects), but

the adjacent vegetation is usually not sufficiently shrubby and the emergent rice plants are not tall and strong enough to support nests, at least during the time when initial nesting is being attempted. Colonies have been rarely observed in rice fields (USFWS 1999), but can use emergent vegetation in canals associated with rice fields. The rice agriculture cycle provides insect forage in the flooded fields during the summer and waste grain forage over winter.

Tricolored black birds do not necessarily return to the same location each year to breed and can vary location between season or within a season. Because the birds have specific breeding habitat requirements and there are limited areas available for breeding, colonies are typically found in the general vicinity of the previous years colony, if the same site is not being used.

The primary concern for the tricolored blackbird's association with rice fields is the use of the habitat as a source of insects and waste grain forage. The birds are highly mobile and fly up to 3 miles from the colony site to forage. During the winter, the birds are more nomadic and move from pastureland and dairy farms to feed, primarily on vegetative matter. The idling of rice fields could affect the behavior of the birds related to foraging distribution patterns. Because environmental measures for the giant garter snake will prevent large blocks of land from being fallowed and will require maintenance of ditch habitat, any effect on foraging behavior is considered less than significant for the tricolored blackbird.

10.2.6.1.15 White-faced Ibis

White-faced Ibis Effects Statement: Crop idling would reduce the SFA acreage in the Sacramento Valley reducing winter forage for this special status species. The white-faced ibis is primarily a winter migrant to the Central Valley. The largest breeding colonies are in Utah, Nevada, and Oregon. Key areas for wintering include the Delevan-Colusa Butte Sink, northwestern Yuba County, the Yolo Bypass, Grasslands Wetlands Complex, and Mendota Wildlife Area. There are reports of breeding colonies in the Central Valley, particularly within the Mendota Wildlife Area and Colusa National Wildlife Area. Within the Central Valley, the species occupies a variety of aquatic and wetland habitats, including rice fields that provide abundant prey (Remsen 1978). The ibis can breed from April to September (USFWS 1999).

Primary cause for the decline in numbers of this species is the drainage of wetlands and destruction of nesting habitat. SFA habitat is one of the many habitat types used by the species, and the species has no particularly affinity to rice fields compared to other wetland habitats.

The diet of the ibis consists of insects, small fish, and miscellaneous invertebrates (Granholm 1991). It feeds in flooded (less than 20 cm water depth) (USFWS 1999; RMI, 1997) or inactive fields that contain its prey items. Surveys of the Sacramento Valley found 66 percent of the ibis concentrated in agricultural fields. In one study up to 53 percent of the foraging ibis were observed in rice stubble (Shuford et. al. 1996).

The white-faced ibis is well adapted to changes in environmental conditions such as drought and flooding; therefore, use of specific areas can vary greatly from year to year depending on habitat conditions (Granholm 1991). The species interaction with the rice crop cycle includes using flooded land in the summer for foraging of prey, and dry or flooded rice fields in the winter, also for prey. Because the species is adaptive and responds to changes in environmental conditions, the effect dude idling of flooded rice fields is considered to be less than significant. No environmental measure is proposed for the species.

10.2.6.1.16 Giant Garter Snake

Giant Garter Snake Effects Statement: Crop idling would reduce the SFA acreage in the Sacramento Valley reducing replacement wetland habitat that this special status species uses year around thereby jeopardizing population numbers. Giant garter snakes' reliance on rice fields and agricultural drainage is due to a lack of viable alternative habitats. Most of its historic wetland habitat has been lost (USFWS 1999). Riparian woodlands do not provide the basking areas the snake requires to warm to activity levels (Hansen and Brode 1980), nor do they provide the pools of concentrated prey such as carp, mosquitofish, and bullfrogs (Rossman et al. 1996) the species relies upon for food. Open river environments make the giant garter snake susceptible to predation by non-native species such as bass and leveed rivers do not provide the snake with grassy banks for basking or elevated areas for hibernation (58 FR 54053, Oct 20, 1993).

Rice fields provide all necessary elements of the giant garter snake habitat. This includes irrigation canals and flooded fields that provide forage and escape, emergent vegetation for cover, and upland areas along canals for basking and dens. Populations of giant garter snakes in the Colusa, Butte, Sutter, and American River Basins are mostly associated with rice field habitats and their connecting irrigation and drainage canals (58 FR 54053, October 20, 1993). Current studies are finding up to 50 percent of observed individuals in rice field habitats (USFWS 1999).

The rice agriculture cycle, as described in Section 10.1.1.14, coincides closely with the habitat requirements of the giant garter snake. The snake hibernates over winter in dens near the fields and thus land management practices that do not involve reconstruction of drainage channels will not affect the snake. (The Rice Council has provided guidance to rice growers in relation to protecting the snake.) When the snake emerges from its burrow in March and April, water is only in the drainage ditches. This helps concentrate prey and facilitates the mating process. After field preparation, the fields are flooded increasing the forage habitat for the snake. When flooded, rice field habitat provides warm shallow open waters of prey for foraging (Hansen 1980, Brode and Hansen 1992, Hansen and Brode 1993). Once the rice plant emerges, the rice field provides cover from predators.

In July to early September, the female snakes give birth. Rice fields continue to provide food and cover for the snake population. Finally, in the fall when the fields are drained, the snake's prey species are concentrated in the drainage ditches. The snakes move into the adjacent drainages that, as long as the vegetation cover is retained, provide the necessary habitat and forage to prepare the snake for

hibernation. The concentration of prey in the canals is a benefit to the snakes inhabiting rice farmland. In the fall, the snakes return to burrows and cracks in the upland area to hibernate. Snakes are generally dormant from November to February (USFWS 1999).

In September, juveniles make extensive use of the pools of concentrated prey that are associated with the temporally coinciding rice field drainage areas. Prey concentrations in drainage pools provide pre-dormancy gorging opportunities for giant garter snakes.

Predation of giant garter snakes is limited to the habitat corridors such as irrigation and drainage ditches. Irrigation ditches provide both mobility and extensive cover for the snake (USFWS 1999). Removal of vegetation can expose snakes to predators, thereby considerably diminishing this particular habitat benefit. The loss of a food source and critical habitat as a result of EWA crop idling actions would have a significant adverse effect on the giant garter snake populations associated with SFA habitat. Environmental measures described in Section 10.2.4 would reduce this effect to a less-than-significant level.

10.2.6.1.17 Western Pond Turtle

Western Pond Turtle Effects Statement: Crop idling would reduce the SFA acreage in the Sacramento Valley reducing habitat for this special status species. The western pond turtle is the only native box turtle widely distributed in the western United States. Historically, the turtle once inhabited the vast permanent and seasonal wetlands of the Central Valley. The draining of wetlands for agriculture and urban development has greatly reduced this species' habitat. The western pond turtle is found in brackish permanent to intermittent aquatic habitats, including marshes, rivers, ponds, streams, and vernal pools. In the Central Valley it is also found in man-made habitats such as irrigation ditches, reservoirs, and ponds. Its preferred habitat is slow moving or quiet water, with emergent vegetation and undercuts for refuge. Protected, grassy uplands with a clay/silt soil are the preferred nesting sites. Because irrigation ditches typically are maintained, they generally do not include all required habitat elements for the turtle, particularly nesting habitat.

In addition to the loss of aquatic habitat, other causes of population decline include increased predation and collecting by man. Poor reproductive success due to predation and nest destruction is also hampering the turtle's recovery.

Females move upland from aquatic habitat to lay from 1 to 13 eggs. Eggs are laid May through July and juveniles hatch during August to October. Juveniles generally stay at the next site over winter. Movement of females from aquatic habitat to the nest and back, and juveniles from the nest, exposes the turtles to predation, particularly in agricultural areas where vegetation cover is controlled.

The diet of the western pond turtle is comprised primarily of small invertebrates, but adults do consume some vegetative matter. In seasonally flooded agricultural habitat, irrigation ditches and flooded rice land can contain required habitat elements for box

turtles. The turtles can forage in the aquatic habitat and bask on adjacent levees. The turtles are active during the spring, summer, and fall when rice preparation, growing, and harvesting is performed, respectively.

Because the western pond turtle can utilize irrigation ditches and rice fields as habitat, any action that dries up the habitat and forces the turtle to migrate to new areas, also exposes the turtle to increased predation. Further reduction of turtle population would be considered significant if it resulted from idling of seasonally flooded agricultural land. Environmental measures described in Section 10.2.4 for the giant garter snake will also be protective of the western pond turtle through the requirements to maintain irrigation ditch levels to six inches of normal and for retaining emergent vegetation with the ditches.

10.2.6.1.18 Wildlife in General

Wildlife Effects Statement: Crop idling would reduce the SFA acreage in the Sacramento Valley reducing habitat and forage for resident and migratory wildlife populations. In addition to the special status species presented above, the EIS/EIR considers other wildlife that are strongly dependent on rice croplands for some portion of their life cycle including waterfowl, wading birds, and shorebirds. This analysis approaches these species as guilds rather than analyzing each one individually. The Aleutian Canada goose was used to represent waterfowl; the great blue heron, great egret, and the snowy egret were used to represent wading birds; and the black tern was used to represent shorebirds. As stated above, the effects to these guilds would be less than significant with the implementation of the environmental measures presented in Section 10.2.4. Additionally, species such as the northern pintail and mallard also use rice fields for pair and brood habitat during the spring and summer. Up to 89,608 acres of rice fields may be lost during these critical times. Fallowing of approximately 20 percent of the current acreage of rice fields in the Sacramento Valley would have the following affects:

- Elimination of "pair" habitat of permanent residents who use winter flooded rice fields during the months in early spring. This will also eliminate "brood" water habitat that would normally be available during the spring and summer when rice is grown.

- Elimination of shallow flooded winter rice fields that wintering waterfowl use for night roosting and for food (vegetation and invertebrates). Flooded rice fields are frequented more than the natural wetlands by invertebrates as the winter progresses. Rice fields are also relied upon more heavily than natural wetlands as the winter progresses for dense cover at night since natural wetlands vegetation becomes prostrate and trampled, thus lacking needed protective cover.

However, there is still a large amount of forage and other habitat available to waterfowl within the Sacramento Valley. Although some waterfowl habitat may be affected, the overall effect is less than significant.

10.2.6.2 Delta

10.2.6.2.1 Introduction to Delta Effects Analysis

EWA acquisitions via groundwater substitution, crop idling, stored reservoir water purchase, stored groundwater purchase, and source shifting would change the timing of Delta flows. Changing the flows in the Delta could potentially affect the growth, maintenance, and reproductive capacity of vegetation in the lower Sacramento River and Delta. Table 10-6 shows the long-term average changes in Delta outflows because of the Flexible Purchase Alternative.

The Flexible Purchase Alternative would result in changes in the Delta, but these changes would remain within the same general range of flows that the Delta experiences. The vegetation in the region has adapted to these flow ranges; therefore, these changes would likely not substantially affect the growth, maintenance, or reproductive capacity of this community.

Table 10-6
Long-term Average Delta Outflow Under Baseline Condition and Flexible Purchase Alternative (Maximum Water Purchase Scenario) Conditions

Month	Monthly Mean Flow[1] (cfs)		Difference		
	Baseline	Flexible Purchase Alternative	(cfs)	(%)[2]	TAF[2]
Oct	7,494	7,494	0	0	0
Nov	14,729	14,729	0	0	0
Dec	29,135	29,762	627	2.2	37.3
Jan	35,403	36,000	597	1.7	35.5
Feb	57,924	58,824	900	1.6	53.5
Mar	53,136	54,665	1,529	2.9	90.9
Apr	29,039	30,674	1,635	5.6	97.3
May	17,995	19,372	1,377	7.7	81.9
Jun	13,767	14,792	1,025	7.4	60.9
Jul	7,915	8,354	439	5.6	26.1
Aug	4,192	4,492	300	7.2	17.9
Sep	5,574	5,884	310	5.6	18.5

[1] Based on 1979-1993 period of record.
[2] Relative difference of the monthly long-term average.

Changes to Delta inflows could result in changes in the position of X_2.[8] Moving the X_2 location closer to the Delta would indicate that the EWA actions were decreasing Delta water quality, which could affect the Tidal Perennial Aquatic habitat. Table 10-7 shows the long-term average changes to the position of X_2. In all months, the X_2 location is closer to the Golden Gate Bridge, indicating better Delta salinity. These results are because of stipulations within the EWA program description that require the long-term average position of X_2 to be maintained through the use of carriage

[8] The distance upstream from the Golden Gate Bridge (in km) at which mixing of freshwater from the Delta inflow and saltwater from the Bay results in a channel bottom salinity of two parts per thousand. Because Delta salinity is primarily a result of seawater intrusion, X_2 is mainly a measure of such intrusion; however, upstream sources such as agricultural drainage from the San Joaquin Valley also contribute to Delta salinity and to the values of X_2.

water releases. Chapter 5, Water Quality, contains additional analysis of Delta water quality, but concludes that EWA water acquisition and management effects would be less-than-significant.

10.2.6.2.2 Tidal Perennial Aquatic

The information presented in Section 10.2.6.2.1 indicates that EWA actions would not have an effect on this community from Baseline Conditions. This community is strongly influenced by global tides and EWA actions will maintain the position of X_2. In summary, changes to Delta inflows would not be of sufficient magnitude and frequency to significantly alter riparian habitat associated with this community. Therefore, the Flexible Purchase Alternative represents a less than significant effect on Delta tidal perennial aquatic habitat.

Table 10-7
Long-term Average Delta X_2 Position under Baseline and Flexible Purchase Alternative (Maximum Water Purchase Scenario) Conditions

Month	Monthly Mean Position[1] (km)		
	Baseline	Flexible Purchase Alternative	Difference
Oct	85.3	84.5	-0.8
Nov	83.6	83.4	-0.2
Dec	80.3	80.2	-0.1
Jan	76.9	76.6	-0.3
Feb	71.7	71.3	-0.4
Mar	66.4	66.0	-0.4
Apr	64.5	63.8	-0.7

Jun	72.0	70.9	-1.1
Jul	75.9	74.7	-1.2
Aug	79.5	78.6	-0.9
Sep	84.5	83.6	-0.9

[1] Kilometers from the Golden Gate Bridge.

10.2.6.2.3 Valley Riverine Aquatic

Valley riverine aquatic habitat in the Delta occurs in Delta waterways such as the Sacramento, San Joaquin, Consumnes, Mokelumne, and Calaveras rivers, and sloughs, streams, and ephemeral creeks. Major waterways in Suisun Bay and Marsh area that are considered VRA habitat include Suisun, Montezuma, and Nurse sloughs. Out of these rivers, the EWA actions would only affect the Sacramento and San Joaquin Rivers. The effects on Valley Riverine Aquatic habitat on these rivers within the Delta would be the same as those described in Section 10.2.6.1.1 for the Upstream in the Delta Region.

10.2.6.2.4 Saline Emergent

EWA acquisitions via groundwater substitution, crop idling, stored reservoir water purchase, stored groundwater purchase, and source shifting would change the timing of Delta inflows, outflows, and pumping operations. Similar to the effects on Tidal Perennial Aquatic habitat, changing flows in the Delta could affect the Saline Emergent community because flow and water quality changes could affect the growth, maintenance, and reproductive capacity of the vegetation within these communities. As discussed in

Section 10.2.6.2.1, the changes in Delta flow and water quality would not be of sufficient magnitude and frequency to cause these effects. Therefore, the Flexible Purchase Alternative would result in less-than-significant effects on saline emergent habitat.

10.2.6.2.5 Tidal Freshwater Emergent

EWA acquisitions via groundwater substitution, crop idling, stored reservoir water purchase, stored groundwater purchase, and source shifting would change the timing of Delta inflows, outflows, and pumping operations. The text in Section 10.2.6.2.2, Tidal Perennial Aquatic, includes an analysis of changes in Delta inflows, outflows, and pumping operations on the Delta communities. The analysis found that the flow changes within the Delta would not have the magnitude and frequency to affect the growth, maintenance, and reproductive capacity of Delta communities. Under Flexible Purchase Alternative, the long-term average position of X_2 would be maintained through the use of carriage water releases. Changes within the Delta would not significantly alter existing tidal freshwater emergent habitats and associated species dependent on the Delta. Therefore, the Flexible Purchase Alternative represents a less than significant effect on tidal freshwater emergent habitat.

10.2.6.2.6 Nontidal Freshwater Permanent Emergent

EWA actions would only affect flows in Delta waterways. Changes in Delta flows will have no affect on nontidal freshwater permanent emergent habitat.

10.2.6.2.7 Natural Seasonal Wetland

EWA actions would only affect flows in Delta waterways. Changes in Delta flows will have no affect on natural seasonal wetland habitat.

10.2.6.2.8 Managed Seasonal Wetland

EWA actions would only affect flows in Delta waterways. Changes in Delta flows will have no affect on managed seasonal wetland habitat.

10.2.6.2.9 Valley/Foothill Riparian

The text in Section 10.2.6.2.2 Tidal Perennial Aquatic includes an analysis of potential direct and indirect effects on Delta NCCP communities, including valley/foothill riparian habitats and associated covered species. The effects presented in Section 10.2.6.2.2 would be the same for the portion of this community within the Delta. The same concerns for increased flow effects on riparian vegetation of upstream Sacramento River remain for the riparian vegetation of the Delta.

10.2.6.3 Export Service Areas

10.2.6.3.1 Lacustrine

Source shifting of Anderson Reservoir would decrease the summer water surface elevation of the reservoirs. EWA agencies could acquire up to 20,000 acre-feet of source shifting capability via agreements with Santa Clara Valley Water District (WD). Source shifting would delay the water amounts that the SWP delivers to the Santa Clara Valley WD, which would cause the Santa Clara Valley WD to draw upon other sources of water in the interim period. The Santa Clara Valley WD would typically

draw water from storage within Anderson Reservoir or temporarily reduce diversions to groundwater storage facilities. The water amounts drawn from each source would be at the discretion of Santa Clara Valley WD, but it would operate each facility within normal operating parameters. The levels of Anderson Reservoir currently vary widely year-to-year as part of normal Santa Clara Valley WD operations and EWA source shifting would occur within normal Santa Clara Valley WD operational parameters. Source shifting would not have adverse effects on lacustrine habitat at Anderson Reservoir.

EWA management of Santa Clara Valley WD water via predelivery could increase the surface water elevation in Anderson Reservoir in the months prior to the high point[9] in San Luis Reservoir. With the EWA, water would be transferred from San Luis Reservoir to Anderson Reservoir or groundwater storage facilities prior to the high point in San Luis Reservoir. Although the amount of water within Anderson Reservoir would increase compared to the Baseline Condition, it would not exceed the existing drawdown zone (for flood control reasons) and inundate established shoreline habitats. Therefore, the effect on vegetation and wildlife would be less than significant.

Borrowing project water from San Luis Reservoir would decrease surface water elevations. Under Baseline Conditions, surface water elevations in San Luis Reservoir would begin to decrease in mid-April. At approximately 300,000 acre-feet, the "low-point problem" at San Luis Reservoir occurs, whereby warm-season algae growth and decreasing summer levels can affect the quality of the reservoir water. EWA actions would be managed to prevent contributing to or aggravating the low point problem. (See Figure 2-13, Section 2.4.2.3.2.) Therefore, the effect of borrowing project water on lacustrine habitat would be less than significant.

Source shifting by DWR at Metropolitan WD reservoirs would decrease the summer surface water elevation of the targeted reservoirs.

Metropolitan WD has many options for source shifting. These options include:

- **Lake Mathews, Lake Perris, Castaic Lake, and Diamond Valley Lake.** Metropolitan WD could delay delivery of SWP water and instead draw its supplies from these storage facilities; accepting the SWP water deliveries at a later date.

- **Semitropic and Arvin Edison.** During wet years, Metropolitan WD could reduce deliveries when they would have otherwise SWP delivered water to storage. Metropolitan WD could then deliver SWP water to Semitropic and Arvin Edison for storage at a later date.

[9] High point is the value at which storage has peaked annually. In San Luis Reservoir, high point occurs approximately in mid-April.

- **Hayfield (upstream aqueduct groundwater storage on the Colorado River).** Metropolitan WD could delay delivery of Colorado River water to Hayfield; the water would be delivered at a later date.

- **Change blend.** Metropolitan WD generally maximizes water sources and quality by blending Colorado River and SWP water 50:50. Metropolitan WD could change the blend to provide water for source shifting.

Lake Mathews

Because the vegetation surrounding Lake Mathews is not dependent upon reservoir water levels changes to water surface elevations would be a less-than-significant effect on vegetation and wildlife.

Lake Perris and Castaic Lake

Metropolitan WD has rights to flexible storage in Castaic Lake and Lake Perris allowing the agency to borrow water from the lakes for up to 5 years, subject to DWR approval. The flexible storage in Castaic Lake is 153,940 acre-feet and 65,000 acre–feet in Lake Perris. Metropolitan WD gained these rights as part of the Monterey Amendments[10], signed in 1995, and has exercised the right several times, including in 2001 as part of the source shifting agreement in that year. The amount of water that could be source shifted under the EWA would fall within the recent operating parameters of both Castaic Lake and Lake Perris.

Diamond Valley Lake

Because the vegetation surrounding Lake Mathews is not dependent upon reservoir water levels, changes to water surface elevations would be a less-than-significant effect on vegetation and wildlife.

Metropolitan WD management of EWA water provided as predelivery could increase the surface water elevation in Diamond Valley Lake, Lake Mathews, and other Metropolitan WD storage facilities. If Metropolitan WD were to accept predelivery water and use it to repay its flexible storage debt in Castaic Lake or Lake Perris, predelivery could affect the surface water elevations in those lakes as well. With the EWA, water could be transferred to Metropolitan WD at any of its turnouts and then to storage in Diamond Valley Lake, Lake Mathews, or other Metropolitan WD storage facilities, or used to repay flexible storage in Castaic Lake or Lake Perris. Although the amount of water within these facilities would increase compared to the Baseline Condition, water surface elevations would not exceed the existing drawdown zone (for flood control reasons) and inundate shoreline habitats. Therefore, the effect on vegetation and wildlife would be less than significant.

---

[10] The Monterey Agreement, signed in 1994 by DWR and SWP water contractors, addresses water supply reliability problems, provides greater flexibility in water operations, and provides greater financial stability for SWP contractors.

10.2.6.3.2 Nontidal Freshwater Permanent Emergent

Borrowing Project water from San Luis Reservoir would decrease surface water elevations. As with all other reservoirs associated with EWA actions, reductions in water surface elevations would not affect shoreline communities such as nontidal freshwater permanent emergent vegetation because this vegetation is not dependent upon lake levels for water. Therefore, the effect of borrowing Project water would be less than significant.

10.2.6.3.3 Upland Cropland

EWA acquisition of water via idling cotton would take cotton land out of production. Cotton land provides extremely marginal habitat and forage to wildlife. Although a maximum of 182,800 acres of cotton would be idled, EWA actions would have less-than-significant effects on upland cropland habitat and associated wildlife.

10.2.7 Environmental Consequences/Environmental Impacts of the Fixed Purchase Alternative

The Fixed Purchase Alternative would involve the same water acquisition and management actions as the Flexible Purchase Alternative, but to a lesser degree. The Fixed Purchase Alternative limits upstream of the Delta transfers to 35,000 acre-feet and export service area transfers to 150, 000 acre-feet. The Fixed Purchase Alternative can acquire its 35,000 acre-feet upstream from the Delta from one or multiple sources. The EWA agencies would be most likely to seek stored reservoir water for the entire purchase; however, the agencies might also rotate acquisitions among diverse sources. This section of the document assumes that the EWA agencies could acquire the 35,000 acre-feet from any mix of upstream-from-the-Delta sources. The Flexible Purchase Alternative allows transfers up to 600, 000 acre-feet and does not specify transfer limits from upstream of the Delta or the export service areas. The effects described in Section 10.2.6 Flexible Purchase Alternative, represent the effects on vegetation and wildlife resources for a maximum transfer amount. Effects considered less than significant under the Flexible Purchase alternative would also be considered less than significant for a lesser transfer amount (The Fixed Purchase Alternative). Table 10-9 (towards the end of the chapter) shows the potential transfer amounts for each alternative and the significance of these transfers on vegetation and wildlife resources.

10.2.7.1 Upstream from the Delta

10.2.7.1.1 Valley Riverine Aquatic/Valley Foothill Riparian

This section analyzes the EWA effects on vegetation within each river system in the Upstream from the Delta Region. These effects would be similar to those discussed in Section 10.2.6.1.1.

Sacramento River

EWA acquisition of Sacramento River contractor water via groundwater substitution and crop idling would decrease Sacramento River flows from Lake Shasta downstream to the point of diversion in June. EWA acquisition of up to 35,000 acre-feet of water via groundwater substitution or up to 35,000 acre-feet from crop idling would decrease monthly

Sacramento River flows by 180 cfs in June. The effect due to this small flow decrease is less than significant.

EWA acquisition of Sacramento River contractor water via groundwater substitution and crop idling would change Sacramento River flows downstream from Lake Shasta in July through September. EWA acquisition of up to 35,000 acre-feet of water via groundwater substitution and up to 35,000 acre-feet from crop idling would potentially increase Sacramento River flows between Lake Shasta and the point of diversion July through September. This change in flow is not considered significant to cause adverse effects.

Feather River

EWA acquisition of Oroville-Wyandotte ID stored reservoir water would decrease flows in the South Fork of the Feather River from December through April and increase flows in the lower Feather River from July through September. Oroville-Wyandotte ID would deliver stored reservoir water for the EWA agencies from October through December, and DWR would store it in Lake Oroville until it could be transferred through the Delta during the following summer. During the rainy season after December, Oroville-Wyandotte ID would refill its reservoirs, which would decrease the flow that travels downstream of Sly Creek and Little Grass Valley Reservoirs. These decreases would occur during rain events during the winter, and would not likely have an effect on flow downstream of Lake Oroville. When the Oroville-Wyandotte ID water is released from Lake Oroville the following summer, this water would increase Feather River flows downstream of Oroville Reservoir from July to September. The section below describes the total increases in lower Feather River flow because of all EWA acquisitions from the Feather River system.

EWA acquisition of water from Western Canal WD, Joint Water Districts, and Garden Highway MWC via crop idling and groundwater substitution would increase Feather River flows in July through September. A maximum of an additional 35,000 acre-feet would be released from Lake Oroville, which would increase flows in the Feather River below the Thermalito Afterbay by a maximum of 212 cfs. The effects of these EWA actions are evaluated in Section 10.2.6.1.1, Feather River for the Flexible Purchase Alternative. The increase in flow in the Feather River would be greater under the Flexible Purchase Alternative than under the Fixed Purchase Alternative. Because no adverse effect was determined under the Flexible Purchase Alternative, no effect would occur under the Fixed Purchase Alternative.

EWA acquisition of Oroville-Wyandotte ID stored reservoir water would increase Feather River flows below Sly Creek and Little Grass Valley Reservoirs to Lake Oroville in November and December. The same amount of water could be transferred under the Fixed Purchase Alternative as described in the Flexible Purchase Alternative. Refer to Section 10.2.6.1.1, Feather River, for a discussion of potential effects.

Yuba River

EWA acquisition of Yuba County WA water via stored reservoir water and groundwater substitution would decrease Yuba River flows downstream of New Bullards Bar Reservoir from April to June and increase flows from July through September. Yuba County WA

would store water from groundwater substitution acquisitions in New Bullards Bar Reservoir until July, when the Delta pumps are available. Storing the water would decrease flows in the Yuba River from Englebright Dam, where the power facilities release Yuba County WA water, to the users' diversion points, typically at Englebright and Daguerre Point Dams. Yuba River flows would decrease by 195 cfs in late spring as farmers use groundwater for irrigation instead of surface water from New Bullards Bar Reservoir.

EWA acquisition of Yuba County WA stored reservoir water and Yuba River contractor water via groundwater substitution and stored reservoir water would increase Yuba River flows, downstream of Englebright Dam, from July to September relative to the Baseline Condition. Releases would be operated to maintain relatively constant flows during this time period in accordance with existing Yuba County WA operations to protect fish and the environment. Therefore, flows under EWA actions would not have a substantial adverse effect on Yuba River VRA habitats used by special-status species or important for wildlife movement or wildlife nurseries. EWA actions would also not have a substantial adverse effect on sensitive natural communities.

American River

EWA acquisition of Placer County WA stored reservoir water would increase American River flows downstream from French Meadows Reservoir to Folsom Lake from June to October. The same amount of water could be transferred under the Fixed Purchase Alternative as described in the Flexible Purchase Alternative. Refer to Section 10.2.6.1.1 American River, for a discussion of potential effects.

EWA acquisition of Placer County WA stored reservoir water would decrease American River flows downstream from French Meadows Reservoir to Folsom Lake during refill of Hell Hole and French Meadows Reservoirs. The same amount of water could be transferred under the Fixed Purchase Alternative as described in the Flexible Purchase Alternative. Refer to Section 10.2.6.1.1, American River, for a discussion of potential effects.

EWA acquisition of Sacramento Groundwater Authority's water via stored groundwater purchase would increase American River flows downstream from Folsom Lake from June through December. The same amount of water could be transferred under the Fixed Purchase Alternative as described in the Flexible Purchase Alternative. Refer to Section 10.2.6.1.1, American River, for a discussion of potential effects.

Merced River

EWA acquisition of Merced ID water via groundwater substitution would decrease Merced River flows downstream from New Exchequer Dam to the point of diversion in April through June. Merced River flows would decrease by approximately 70 cfs. An equivalent amount of water could be sold to the EWA agencies under the Fixed Purchase Alternative, as is described under the Flexible Purchase Alternative. Refer to Section 10.2.6.1.1 Merced River, for a discussion of potential effects.

San Joaquin River

EWA acquisition of MID water via groundwater substitution would increase San Joaquin River flows, below the San Joaquin-Merced river confluence, during the fall, relative to the Baseline Condition. Flows in the San Joaquin River would not change during the summer because it is downstream of Lake McSwain. Under the Fixed Purchase Alternative, long-term average flows during March through October on the San Joaquin River below its confluence with the Merced River would be essentially the same as the Baseline Condition.

10.2.7.1.2 Montane Riverine Aquatic/Montane Riparian

Sacramento River

Montane Riverine Aquatic habitat occurs on the Sacramento River between approximately Red Bluff, CA and Lake Shasta. The analysis in Section 10.2.7.1 Valley Riverine Aquatic also applies to montane riverine aquatic. Therefore:

EWA acquisition of Sacramento River contractor water via groundwater substitution and crop idling under the Fixed Purchase Alternative would change Sacramento River flows from June through September. From June to September, EWA acquisition of Sacramento River contractor water would slightly increase or decrease Sacramento River flows (depending on the Delta pump availability) relative to the ESA Baseline Condition.

Therefore, flows under EWA actions would not have a substantial adverse effect on Sacramento River MRA habitats used by special-status species or important for wildlife movement or wildlife nurseries. EWA actions would also not have a substantial adverse effect on sensitive natural communities.

Feather River

EWA acquisition of Oroville-Wyandotte ID stored reservoir water would increase flows in the South Fork of the Feather River from October through December and decreases flows during refill. Oroville-Wyandotte ID would deliver stored reservoir water for the EWA agencies from October through December, and DWR would store it in Lake Oroville until it could be transferred through the Delta during the following summer. During the rainy season after December, Oroville-Wyandotte ID would refill its reservoirs, which would decrease the flow that travels downstream of Sly Creek and Little Grass Valley Reservoirs.

Therefore, flows under EWA actions would not have a substantial adverse effect on Feather River MRA habitats used by special-status species or important for wildlife movement or wildlife nurseries. EWA actions would also not have a substantial adverse effect on sensitive natural communities.

Yuba River

Montane Riverine Aquatic habitat occurs on the Yuba River between approximately Timbuctoo Bend and New Bullards Bar Reservoir. The analysis in Section 10.2.7.1.1 Valley Riverine Aquatic also applies to montane riverine aquatic. Therefore:

EWA acquisition of Yuba County WA water via stored reservoir water and groundwater substitution would decrease Yuba River flows downstream of New Bullards Bar Reservoir from April to June and increase flows from July through September. Yuba County WA would store water from groundwater substitution acquisitions in New Bullards Bar Reservoir until July, when the Delta pumps are available. Storing the water would decrease flows in the Yuba River from Englebright Dam, where the power facilities release Yuba County WA water, to the users' diversion points, typically at Englebright and Daguerre Point Dams. Yuba River flows would decrease in late spring as farmers use groundwater for irrigation instead of surface water from New Bullards Bar Reservoir.

EWA acquisition of Yuba County WA stored reservoir water and Yuba River contractor water via groundwater substitution and stored reservoir water would increase Yuba River flows, downstream of Englebright Dam, from July to September relative to the Baseline Condition. Releases would be operated to maintain relatively constant flows during this time period in accordance with existing Yuba County WA operations to protect fish and the environment. Therefore, flows under EWA actions would not have a substantial adverse effect on Yuba River VRA habitats used by special-status species or important for wildlife movement or wildlife nurseries. EWA actions would also not have a substantial adverse effect on sensitive natural communities.

American River

EWA acquisition of Placer County WA stored reservoir water under the Fixed Purchase Alternative would increase flows in the Middle Fork of the American River from June to December. American River flows would increase from June through December because of releases from French Meadows and Hell Hole Reservoirs. These changes are not of sufficient magnitude or frequency to affect streambanks and existing aquatic or riparian species dependent on American River flows.

EWA acquisition of Placer County WA stored reservoir water would decrease flows in the Middle Fork of the American River compared to the Baseline Condition while the reservoir refills during winter months. During the rainy season after December, Placer County WA would refill its reservoirs, which would decrease the flow that travels downstream of French Meadows, and Hell Hole Reservoirs.

Therefore, flows under EWA actions would not have a substantial adverse effect on American River MRA habitats used by special-status species or important for wildlife movement or wildlife nurseries. EWA actions would also not have a substantial adverse effect on sensitive natural communities.

Merced River

Montane Riverine Aquatic habitat occurs on the Merced River between approximately Merced Falls and Lake McClure. The analysis in Section 10.2.7.1.1 Valley Riverine Aquatic also applies to montane riverine aquatic. Therefore:

EWA acquisition of Merced ID water via groundwater substitution would decrease Merced River summer flows and increase Merced River fall flows relative to the Baseline Condition. Merced ID would hold the EWA transfer water in Lake McClure until the fall, when it would release the water downstream. This pattern would decrease flows downstream of New Exchequer Dam in the summer, but only for the short distance between New Exchequer Dam and Lake McSwain (the typical diversion point). EWA acquisition of Merced ID water via groundwater substitution would increase Merced River flows in fall relative to the Baseline Condition as the water is released from Lake McClure.

Therefore, flows under EWA actions would not have a substantial adverse effect on Merced River MRA habitats used by special-status species or important for wildlife movement or wildlife nurseries. EWA actions would also not have a substantial adverse effect on sensitive natural communities.

10.2.7.1.3 Lacustrine

Comparing EWA actions to the Baseline Condition determines project effects. Reservoirs fluctuate seasonally in response to use and hydrology; therefore, this normal fluctuation creates the Baseline Condition. EWA actions further modify these fluctuations, sometimes accentuating changes and other times attenuating changes in reservoir levels.

Sacramento River

EWA acquisition of Sacramento River contractor water via groundwater substitution and crop idling would change the timing of releases from Lake Shasta. Lake Shasta would hold back at most 35,000 acre-feet that would have been released under the Baseline Condition. The lake level would decline slower in June. Then the lake level would decline faster in July and August compared to the Baseline Condition; however, end of month elevation in September would be the same as the Baseline Condition because of reduced releases during September. The small changes during these months would not be enough to affect the lacustrine habitat within the lake or surrounding the lake perimeter. The water source for riparian vegetation will not be affected and the upland scrub vegetation surrounding the reservoir does not rely on the reservoir for its water source. Therefore, the change in Lake Shasta water surface elevation would have a less-than-significant effect on the lacustrine habitat used by special-status species or other wildlife, particularly as wildlife movement corridors or nurseries along the water edge.

Feather River

EWA acquisition of Oroville-Wyandotte Irrigation District (Oroville-Wyandotte ID) stored reservoir water would decrease surface water elevations December until refill for Sly Creek and Little Grass Valley Reservoirs. Little Grass Valley and Sly Creek Reservoirs are upstream from Lake Oroville on the Feather River. These reservoirs would release a combined maximum of 15,000 acre-feet of water from November to December. The same amount of water could be transferred under the Fixed Purchase Alternative as described in the Flexible Purchase Alternative. Refer to Section 10.2.6.1.3, Feather River, for a discussion of potential effects. The effects of the Flexible Purchase

Alternative are considered less than significant; the effects of the Fixed Purchase Alternative are also considered less than significant.

EWA acquisition of water from Western Canal WD, Joint Water Districts, and Garden Highway MWC via crop idling and groundwater substitution would increase the surface water elevation April to June and decrease the surface water elevation in July and August in Lake Oroville compared to the Baseline Condition. EWA could acquire up to 35,000 acre-feet of water via groundwater substitution or up to 35,000 acre-feet from crop idling. Effects on Lake Oroville from an increase (April through June) and decrease (July and August) in surface water elevation are evaluated in Section 10.2.6.1.1, Feather River for the Flexible Purchase Alternative. There would be less change in surface water elevation under the Fixed Purchase Alternative than under the Flexible Purchase Alternative. Because there were no significant effects under the Flexible Purchase Alternative, there are no significant effects under the Fixed Purchase Alternative.

Yuba River

EWA acquisition of water from Yuba County Water Agency (Yuba County WA) via stored reservoir water and groundwater substitution would alter the surface water elevation April to refill at New Bullards Bar Reservoir. EWA agencies would acquire 35,000 acre-feet through groundwater substitution. During April through June, New Bullards Bar Reservoir would hold back water that would have been released under the Baseline Condition. By the end of June, the surface water elevation in the reservoir would be, at most, 2 feet higher than under the Baseline Condition. An increase in the surface water elevation would only inundate the existing drawdown zone and would not affect vegetation and wildlife.

EWA acquisition of Yuba County Water Agency (Yuba County WA) stored reservoir water would decrease surface water elevations July to refill at New Bullards Bar Reservoir. New Bullards Bar Reservoir would release, at a maximum, 35,000 acre-feet of water to be used as an EWA asset. Yuba County WA would not enter into a transfer agreement unless local needs, instream flows, and system demand requirements were met. If these elements were met, EWA agencies could acquire up to 35,000 acre-feet, decreasing the reservoir elevation 8 feet by September. Again, the drawdown zone is vegetated primarily with non-native herbaceous plants and scattered willow shrubs that do not form a contiguous riparian community and would not be affected by decreases in water levels caused by EWA actions (CALFED 1998). Therefore, the EWA acquisition of Yuba County WA water and its effects on lacustrine habitat are considered less than significant.

American River

EWA acquisition of Placer County WA stored reservoir water would decrease surface water elevations June to refill at Hell Hole and/or French Meadows Reservoirs. Hell Hole Reservoir and French Meadows Reservoir would release a combined maximum of 20,000 acre-feet of water. An equivalent amount of water could be sold to the EWA agencies under the Fixed Purchase Alternative, as is described under the Flexible Purchase Alternative. Refer to Section 10.2.6.1.1, American River, for a discussion of

potential effects. The effects of the Flexible Purchase Alternative are considered less than significant; the effects of the Fixed Purchase Alternative are also considered less than significant.

EWA acquisition of Sacramento Groundwater Authority's water via stored groundwater purchase and Placer County WA's water via stored reservoir water would change surface water elevations in Folsom Lake. During July and August, the surface water elevation at Folsom Lake would be lower than the Baseline Condition. The lake level would decline faster in July and August compared to the Baseline Condition; however, end of month elevation in September would be the same as the Baseline Condition because of reduced releases during September. Therefore, the change in Folsom Lake surface water elevations would have less-than-significant effects on lacustrine habitat used by special-status species or other wildlife, particularly as wildlife movement corridors or nurseries.

Merced River

EWA acquisition of Merced ID water via groundwater substitution would increase the water surface elevation in Lake McClure compared to the Baseline Condition. EWA agencies could acquire 25,000 acre-feet through groundwater substitution. As shown in Figure 14-13, water levels in Lake McClure would only increase. An increase in surface water elevation would have a beneficial effect on the amount of lacustrine habitat.

10.2.7.1.4 Nontidal Freshwater Permanent Emergent

In the Upstream from the Delta Region, the lowering of water tables as part of groundwater substitution actions could affect this habitat by potentially disrupting groundwater to surface water interactions that may support freshwater permanent emergent habitat. However, a well adequacy review to preclude pumping in areas with groundwater to surface water interactions will occur prior to all groundwater actions to prevent effect on nontidal freshwater permanent emergent habitat. Effects on nontidal freshwater permanent emergent habitat and associated special-status and other wildlife are less than significant.

10.2.7.1.5 Natural Seasonal Wetland

Groundwater pumping, as a part of groundwater substitution or groundwater purchase actions, in areas where there is direct connection between groundwater and surface water, could affect groundwater hydrology (lower the groundwater table) thereby drying up some natural seasonal wetlands. As an environmental measure, the EWA agencies will review all groundwater substitution and purchase proposals to ensure that there is no groundwater to surface water interaction that may be affected by groundwater pumping. The groundwater mitigation measures also include a mitigation response (e.g., cease pumping or provide alternative surface water source) should an undiscovered groundwater to surface water interaction become evident. (See Section 6.2.7.) Effects on natural seasonal wetland habitat and associated special-status and other wildlife are less than significant.

10.2.7.1.6 Managed Seasonal Wetland

Groundwater substitution and crop idling actions could have adverse effects (dry up) on managed seasonal wetlands. The project effects on natural seasonal wetlands and associated environmental measures outlined in the previous section are also applicable for managed seasonal wetland habitats.

In addition, both groundwater substitution and crop idling actions could result in less water in agriculture supply and return flow ditches, potentially resulting in the desiccation of managed seasonal wetlands. Project effects on agricultural water supplies caused by these two EWA actions are detailed in the sections below.

Groundwater Substitution Transfers in the Sacramento Valley

Groundwater substitution transfers would decrease flows in agricultural delivery ditches. When water agencies agree to sell water to the EWA agencies through groundwater substitution transfers, the water agencies help to identify willing sellers within each area. The sellers then forgo their surface water supplies and substitute water supplies with groundwater. This change results in less diversion into the agricultural delivery system, which could affect species within the delivery ditches. This decrease is likely to adversely affect the species and vegetation that depend on this flow. Measures incorporated into the project would reduce effects to a less-than-significant level. (See Section 10.2.4.)

Crop Idling Transfers

The effects of crop idling transfers on managed seasonal wetlands depend on the location of the transfers. The following section is divided by river system to fully explain these potential effects.

Sacramento River

EWA acquisition of water via crop idling would reduce the water supply for managed seasonal wetlands that rely on return flows from fields that would be idled. Glenn, Colusa, and Yolo Counties could idle up to 10,600 acres. EWA agencies would purchase approximately 3.3 acre-feet per acre (the amount of water consumed by the crop); however, under the Baseline Condition, water agencies divert additional water from the Sacramento River to account for system losses. System losses include conveyance losses (evaporation or percolation within the conveyance system), riparian evapotranspiration (water used by vegetation along the conveyance system), and on-farm losses (deep percolation to groundwater or tailwater runoff). The amount of water diverted varies depending on the amount of system losses.

If farmers idled their crops, their water agency would reduce diversions by the 3.3 acre-feet per acre plus the additional amount that goes to on-farm losses. Of this additional amount that is applied to fields in the Baseline Condition, a portion percolates into the groundwater aquifer below and a portion runs off the field back into the conveyance system. This "tailwater" that runs back into the conveyance system could then be used again by managed wetlands downstream on the conveyance system. If farmers idled land, tailwater would no longer be available to downstream users, either other farmers or managed wetlands.

Few managed seasonal wetlands exist downstream of the water agencies that may sell water to the EWA agencies via crop idling. These wetlands, however, have the potential to be adversely affected by the reduction in return flows. The measures in Section 10.2.4 would reduce effects to managed seasonal wetlands to a less-than-significant level.

Feather River

EWA acquisition of water via crop idling would reduce the water supply for managed seasonal wetlands that rely on the return flows from fields that would be idled. Butte and Sutter Counties could idle up to 10,600 acres. As described above for the Sacramento River, idling these fields would reduce tailwater, which could reduce supplies to downstream wetlands. Several of the agencies within Butte and Sutter Counties discharge return flows from the irrigation systems into Butte Creek, which provides water for several managed seasonal wetlands. The reduction in return flows has the potential to adversely affect these managed seasonal wetlands. The environmental measures in Section 10.2.4 would reduce effects to managed seasonal wetlands to a less-than-significant level.

American River

EWA acquisition of water via crop idling would reduce the water supply for managed seasonal wetlands that rely on return flows from fields that would be idled. Placer County could idle up to 3,280 acres. As described above for the Sacramento River, idling these fields would reduce tailwater, which could reduce supplies to downstream wetlands. The reduction in return flows has the potential to adversely affect managed seasonal wetlands. The environmental measures in Section 10.2.4 would reduce effects to managed seasonal wetlands to a less-than-significant level.

10.2.7.1.7 Seasonally Flooded Agriculture

Crop idling would reduce the rice acreage in the Sacramento Valley. Table 10-8 displays SFA acreage and waste grain reduction for the maximum acreage of crop idling anticipated for all counties where idling action could occur for the EWA program Fixed Purchase Alternative. These numbers reflect the maximum water transfers (for all water programs acquiring water through crop idling) based on the project limitation of 15,000 acres in Glenn, Colusa, or Yolo Counties and 10,600 acres in Butte, Sutter, and Placer Counties, or a 20 percent maximum crop acreage idled per county. Idling this acreage would reduce the extent of habitat available to those special-status species dependent upon SFA for some portion of their lifecycle (identified with an * in Table 10-3), which is likely to adversely affect those species. Details regarding effects to these species are presented in Section 10.2.6.1.7 for the Flexible Purchase Alternative. Because the Fixed Purchase alternative would involve less acreage, the effects would be similar or less than those of the Flexible Purchase Alternative. Section 10.2.4 proposes environmental measures to help minimize any adverse effects to special-status species.

Table 10-8 also displays the reduction in the availability of waste grain as forage to wildlife by county and total for all crop idling actions (depending on agricultural practices). This amount represents a potentially adverse effect to those special-status

species dependent upon waste grain for a large portion of their forage (identified with an * in Table 10-3). Environmental measures proposed in Section 10.2.4 help to minimize any adverse effects to special-status species.

Table 10-8
Seasonally Flooded Agriculture Acreage and Waste Grain Reductions in Each County Based on Crop Idling Maximum Purchases under the Fixed Purchase Alternative

	Rice Acreage (97 Ag Census) (AC)	Idled Acreage (AC)	Percent Rice Acreage (%)	Waste Grain per Acre (lbs)	Total Waste Grain (million lbs)	Waste Grain Loss (million lbs)	Percent Waste Grain Loss (%)	Total Acre-Feet of Water Available for EWA Fish Actions (TAF)	Potential Square Miles Idled
Butte	95,120	10,600	11	350	33.3	3.7	11	35.0	17
Colusa	132,338	15,000	11	350	46.3	5.2	11	49.5	23
Glenn	83,777	15,000	18	350	29.3	5.2	18	49.5	23
Placer	16,379	3,280	20	350	5.7	1.1	20	10.8	5
Sutter	96,722	10,600	11	350	33.9	3.7	11	35.0	17
Yolo	23,822	4,770	20	350	8.3	1.7	20	15.7	7
Total	448,158	59,250	13	350	156.9	20.7	13	195.5	93

Associated with the idling of SFA is the potential loss of water within adjacent irrigation and return ditches in all 6 counties. EWA agency acquired water would not enter water agencies' distribution systems because it is no longer being delivered to the agricultural users, and unused flows from the fields would not return to the delivery system. These changes have the potential to reduce flow in these ditches, thereby reducing the value of habitat provided. Some irrigation ditches provide forage, resting, and nesting habitat and serve as migration corridors. Devaluing or losing this habitat could affect giant garter snakes, herons, egrets, western pond turtles, etc. This decrease to water in agricultural ditches is potentially an adverse effect to these special-status species. Environmental measures proposed in Section 10.2.4 help to minimize any adverse effects to special-status species.

Associated with the idling of SFA is the potential for fragmentation of seasonally flooded agriculture land habitat. Assuming the maximum acreage is fallowed, a total of 93 square miles of formerly flooded land would be dry in all 6 counties over the late spring, summer, and early fall months. This impact would be significant if it occurred as one contiguous block of SFA. The idled land would have the potential to interfere with wildlife migration and the dispersal of individuals within a metapopulation (hence a loss of genetic diversity). The inability of a snake to migrate to more suitable habitat would potentially be an adverse effect to this special-status species, especially those populations that are succumbing to other population pressures. Environmental measures proposed in Section 10.2.4 help to minimize any adverse effects to special-status species.

Wildlife strongly dependent on rice croplands for some portion of their life cycle includes waterfowl, wading birds, and shorebirds. This analysis approaches these species as guilds rather than analyzing each one individually. The Aleutian Canada goose was used to represent waterfowl; the great blue heron was used to represent wading birds; and the black tern was used to represent shorebirds. As stated above, the effects to these guilds would be less than significant with the implementation of the environmental measures in Section 10.2.4.

10.2.7.2 Delta

10.2.7.2.1 Tidal Perennial Aquatic

EWA acquisitions via groundwater substitution, crop idling, stored reservoir water purchase, stored groundwater purchase, and source shifting change the timing of Delta pumping operations, and have the potential to result in changes to Delta inflows and associated parameters. Potential changes in lower Sacramento River flows can result in changes in the position of X_2. Under EWA actions, long-term average flows in the lower Sacramento River at Freeport would be similar relative to the Baseline Condition. Under EWA actions, the long-term average position of X_2 would be maintained through the use of carriage water releases and other EWA asset directed releases controlling X_2, relative to the Baseline Condition.

In summary, changes to Delta inflows would not be of sufficient magnitude and frequency to significantly alter existing riparian and wetland habitat found in the Delta. Therefore, the Fixed Purchase Alternative represents a less than significant effect on Delta tidal perennial aquatic habitat.

10.2.7.2.2 Valley Riverine Aquatic

Valley riverine aquatic habitat in the Delta occurs in Delta waterways such as the Sacramento, San Joaquin, Consumnes, Mokelumne, and Calaveras rivers, and sloughs, streams, and ephemeral creeks. Major waterways in Suisun Bay and Marsh area that are considered VRA habitat include Suisun, Montezuma, and Nurse sloughs.

EWA acquisition of water via groundwater substitution, groundwater purchase, crop idling, and stored reservoir water purchase would change Sacramento River flows from June through September. From June to September, EWA acquisition of Sacramento River contractor water would slightly increase or decrease Sacramento River flows (depending on the Delta pump availability) relative to the Baseline Condition. However, the Fixed Purchase Alternative would not shift flows outside the long-term average on the Sacramento River.

10.2.7.2.3 Saline Emergent

The text in Section 10.2.7.2.1 Tidal Perennial Aquatic includes an analysis of potential direct and indirect effects on Delta NCCP communities, including saline emergent habitats and associated covered species.

In summary, under the Fixed Purchase Alternative, long-term average flows in the lower Sacramento River at Freeport would be similar relative to the Baseline Condition. Under the Fixed Purchase Alternative, the long-term average position of

X_2 would be maintained through the use of carriage water releases and other EWA asset directed releases controlling X_2, relative to the Baseline Condition. Changes to Delta inflows would not be of sufficient magnitude and frequency to significantly alter existing saline emergent habitats and associated species dependent on the Delta. Therefore, the Fixed Purchase Alternative represents a less than significant effect on saline emergent habitat.

10.2.7.2.4 Tidal Freshwater Emergent

The text in Section 10.2.7.2.1 Tidal Perennial Aquatic includes an analysis of potential direct and indirect effects on Delta NCCP communities, including tidal freshwater emergent habitats and associated covered species.

In summary, under the Fixed Purchase Alternative, long-term average flows in the lower Sacramento River at Freeport would be similar relative to the Baseline Condition. Under the Fixed Purchase Alternative, the long-term average position of X_2 would be maintained through the use of carriage water releases and other EWA asset directed releases controlling X_2, relative to the Baseline Condition. Changes to Delta inflows would not be of sufficient magnitude and frequency to significantly alter existing tidal freshwater emergent habitats and associated species dependent on the Delta. Therefore, the Fixed Purchase Alternative represents a less than significant effect on tidal freshwater emergent habitat.

10.2.7.2.5 Nontidal Freshwater Permanent Emergent

EWA actions would only affect flows in Delta waterways. Changes in Delta flows will have no affect on nontidal freshwater permanent emergent habitat.

10.2.7.2.6 Natural Seasonal Wetland

EWA actions would only affect flows in Delta waterways. Changes in Delta flows will have no effect on natural seasonal wetland habitat.

10.2.7.2.7 Managed Seasonal Wetland

EWA actions would only affect flows in Delta waterways. Changes in Delta flows will have no effect on managed seasonal wetland habitat.

10.2.7.2.8 Valley/Foothill Riparian

The text in Section 10.2.7.2.1 Tidal Perennial Aquatic includes an analysis of potential direct and indirect effects on Delta NCCP communities, including valley/foothill riparian habitats and associated covered species.

In summary, under the Fixed Purchase Alternative, long-term average flows in the lower Sacramento River at Freeport would be similar relative to the Baseline Condition. Changes to Delta inflows would not be of sufficient magnitude and frequency to significantly alter existing valley/foothill riparian habitats and associated species dependent on the Delta. Therefore, the Fixed Purchase Alternative represents a less than significant effect on valley/foothill riparian habitat.

10.2.7.3 Export Service Areas

10.2.7.3.1 Lacustrine

Source shifting of Anderson Reservoir would decrease the summer water surface elevation of the reservoirs. EWA agencies could acquire up to 20,000 acre-feet of source shifting capability via agreements with Santa Clara Valley Water District (WD). Source shifting would delay the water amounts that the SWP delivers to the Santa Clara Valley WD, which would cause the Santa Clara Valley WD to draw upon other sources of water in the interim period. The Santa Clara Valley WD would typically draw water storage within Anderson Reservoir or temporarily reduce diversions to groundwater storage facilities. The water amounts drawn from each source would be at the discretion of Santa Clara Valley WD, but it would operate each facility within normal operating parameters. The levels of Anderson Reservoir currently vary widely year-to-year as part of normal Santa Clara Valley WD operations and EWA source shifting would occur within normal Santa Clara Valley WD operational parameters. Source shifting would not have adverse effects on lacustrine habitat at Anderson Reservoir.

EWA management of Santa Clara Valley WD water via predelivery could increase the surface water elevation in Anderson Reservoir in the months prior to the high point[11] in San Luis Reservoir. The effects of predelivery under the Fixed Purchase Alternative are equivalent to the effects as described under the Flexible Purchase Alternative because the transfer amounts are the same under both Alternatives. Therefore, the effect of predelivery on vegetation and wildlife would be less than significant.

Borrowing project water from San Luis Reservoir would decrease surface water elevations. Under Baseline Conditions, surface water elevations in San Luis Reservoir would begin to decrease in mid-April. At approximately 300,000 acre-feet, the low-point problem at San Luis Reservoir occurs, whereby warm-season algae growth and decreasing summer levels can affect the quality of the reservoir water and impair the ability of urban water agencies to treat the water adequately for municipal and industrial uses. EWA actions would be managed to prevent contributing to or aggravating the low point problem. (See Figure 2-13, Section 2.4.2.3.2.) Under the Baseline Condition, San Luis Reservoir is drawn down each summer; however, vegetation surrounding the reservoir and within the drawdown zone would not be affected. Therefore, the effect of borrowing project water would be less than significant.

Source shifting by Metropolitan WD would decrease the summer surface water elevation of reservoirs used by Metropolitan WD. Source shifting options by Metropolitan WD would be the same under the Fixed Purchase Alternative as those described under the Flexible Purchase Alternative. Metropolitan WD could source shift a maximum of 200,000 acre-feet. Metropolitan WD has rights to flexible storage of over 153,940 acre-feet and 65,000 acre-feet of flexible storage in Castaic Lake and Lake Perris, respectively. The action of source shifting would fall under current operating

[11] High point is the value at which storage has peaked annually. In San Luis Reservoir, high point occurs approximately in mid-April.

parameters; therefore, there would be no change from the Baseline Condition and a less-than-significant effect on lacustrine habitats.

Metropolitan WD management of EWA water provided as predelivery could increase the surface water elevation in Diamond Valley Lake, Lake Mathews, and other Metropolitan WD storage facilities. If Metropolitan WD were to accept predelivery water and use it to repay its flexible storage debt in Castaic Lake or Lake Perris, predelivery could affect the surface water elevations in those lakes as well. The effects of predelivery under the Fixed Purchase Alternative are equivalent to the effects as described under the Flexible Purchase Alternative because the transfer amounts are the same under both Alternatives. Therefore, the effect of predelivery on vegetation and wildlife would be less than significant.

10.2.7.3.2 Nontidal Freshwater Permanent Emergent

As with all other reservoirs associated with EWA actions, reductions in water surface elevations would not affect shoreline such as nontidal freshwater permanent emergent vegetation because this vegetation is not dependent upon lake levels for water. Therefore, the effect of borrowing project water would be less than significant.

10.2.7.3.3 Upland Cropland

Cotton land provides extremely marginal habitat and forage to wildlife. Although a maximum of 177,300 acres of cotton would be idled, EWA actions would have no adverse effects on upland cropland habitat and associated wildlife.

10.2.8 Comparative Analysis of Alternatives

10.2.8.1 Upstream from the Delta

In the Upstream from the Delta region, the Fixed Purchase Alternative would be limited to a maximum acquisition of 35,000 acre-feet from all sources of water. This amount could typically be obtained from stored reservoir water purchases in most year types. In very dry years, stored reservoir water may not be available, and the EWA agencies would need to look to other sources.

The Flexible Purchase Alternative could involve the purchase of up to 600,000 acre-feet of water from all sources upstream from the Delta. EWA agencies would prefer to purchase water from upstream sources because the water is generally less expensive. The amount that could be purchased would be limited by the capacity of the Delta export pumps to move the water to export areas south of the Delta. During wet years, excess pump capacity may be limited to between 50,000 and 60,000 acre-feet of EWA asset water because the pumps primarily would be used to export state and federal project water to export service area users. During dry years, when there would be less Project water available for pumping (and therefore the pumps would have greater availability capacity), the EWA Project Agencies could acquire up to 600,000 acre-feet of water from sources upstream from the Delta. Table 10-9 compares the Flexible and Fixed Purchase Alternatives to the Baseline Condition.

The EWA Project Agencies usually prefer to purchase stored reservoir water because it is the least expensive option. In dry years for the Fixed Purchase Alternative, they would likely purchase all stored reservoir water available, and then look to other options for the remainder of their purchases. The effects on vegetation and wildlife would be greater during these years. In wet years, a portion of the stored reservoir water available would likely provide the entire amount of water that could be moved through the Delta. During these years the effects on vegetation and wildlife would be minimal.

The potential for effects on vegetation and wildlife during wet years for the Flexible Purchase Alternative would be very similar to the Fixed Purchase Alternative. That is, during wet years, acquisitions would most likely be from stored water sources and groundwater and crop idling sources would not be used. However, as rainfall amounts for areas north of the Delta decrease, reflecting dry year conditions, the greater capacity of the export pumps to move EWA assets could result in a greater reliance on crop idling and groundwater resources for the additional EWA acquisitions. If the EWA Project Agencies were to acquire 600,000 acre-feet upstream from the Delta, they would need to utilize most available sources, which would include stored reservoir water, groundwater substitution, groundwater purchase, and crop idling. Although the groundwater mitigation measures and socioeconomic thresholds would be employed to minimize the potential for impact, the greater reliance on crop idling and groundwater acquisitions during dry years would result in the Flexible Purchase Alternative having a greater potential for effects on vegetation and wildlife than the Fixed Purchase Alternative.

10.2.8.2 Export Service Area

EWA asset acquisitions in the Export Service Area under the Fixed Purchase Alternative would be limited to 150,000 acre-feet from stored groundwater and crop idling sources. Stored groundwater would be acquired from agencies that have previously stored water in the ground (e.g., Kern Water Bank). Therefore, there would not be an adverse effect on vegetation and wildlife in the Export Service Area under the Fixed Purchase Alternative. Crop idling would only occur on cotton fields. Cotton provides poor quality habitat for wildlife; therefore, any amount of idling of these fields would not affect vegetation wildlife.

EWA asset acquisitions in the Export Service Area under the Flexible Purchase Alternative would be dependent on the water year type north of the Delta. Export pump capacity during wet years would limit the ability of the EWA Project Agencies to move assets through the Delta, requiring reliance on greater purchase amounts from export area sources. During wet years, acquisitions within the export service area could involve up to 540,000 acre-feet of assets. The EWA agencies would acquire assets from stored groundwater and idled cropland sources. Because groundwater would be purchased from previously stored banks of water, no adverse effects to groundwater resources within the export service area would be expected under the Flexible Purchase Alternative. Again, crop idling would occur on cotton fields. There would be no impacts to vegetation and wildlife.

Table 10-9

Export Service Area	Crop idling	Conversion of cotton crop to bare fields	Reduced cotton crop acreage in Fresno, Tulare, Kings, and Kern Counties	Idle a maximum of 182,800 acres.	Idle a maximum of 177,300 acres.	Less-than-significant	Less-than-significant	Cotton does not provide suitable habitat for wildlife
	Stored Groundwater Purchase	Release of water from groundwater storage	Decrease in the amount of water available through KCWA water banks	A maximum of 165,000 acre-feet from water bank.	A maximum of 165,000 acre-feet from water bank.	Less-than-significant	Less-than-significant	
	Source Shifting	Water is released from SWP and/or Metropolitan Water District reservoirs	Decreased water levels in Castaic, Perris, Diamond Valley, and Mathews	Water levels decreased by a maximum of 200,000 acre-feet.	Water levels decreased by a maximum of 200,000 acre-feet.	Less-than-significant	Less-than-significant	
		Water is drawn from Anderson Reservoir	Decreased levels in Anderson Reservoir compared to the Baseline Condition.	Water levels decreased by a maximum if 20,000 acre-feet.	Water levels decreased by a maximum if 20,000 acre-feet.	Less-than-significant	Less-than-significant	
	Borrowed Project Water	EWA water is released from San Luis Reservoir earlier in the year compared to Baseline Conditions	Decreased water levels in San Luis Reservoir	San Luis is lower in July and August than under Baseline Condition	San Luis is lower in July and August than under Baseline Condition	Less-than-significant	Less-than-significant	

10.2.9 Mitigation Measures

The environmental measures presented in Section 10.2.4 have been developed to reduce effects to vegetation and wildlife to less than significant levels. As such no mitigation measures are proposed for vegetation and wildlife.

10.2.10 Potentially Significant Unavoidable Impacts

All effects on vegetation and wildlife would be less than significant with the environmental measures listed in Section 10.2.4; therefore no potentially significant unavoidable impacts occur within this resource category.

10.2.11 Cumulative Effects

The analysis of cumulative effects on vegetation and wildlife compares potential effects from other water transfer related actions and other projects occurring in the EWA action area to the Baseline Condition by evaluating the total effects to changes in quantity and/or quality of vegetation communities and the effect of these changes to associated wildlife. For example, if other water transfer programs include crop idling within the Sacramento Valley then the effects of the additional sources of crop idling when combined with EWA actions could be cumulatively significant.

A cumulative analysis for groundwater purchase actions can be found in Chapter 6 Section 6.2.9. The effect on vegetation and wildlife of each program considered in the cumulative analysis has been evaluated and would be covered by environmental documents developed for each groundwater program.

10.2.11.1 Upstream from the Delta

As described in Chapter 22, five water supply programs, in addition to EWA, are being included in the cumulative effects analysis. All five involve water acquisition upstream from the Delta and two downstream from the Delta.

Upstream from the Delta, four programs (Sacramento Valley Water Management Agreement, Dry Year Purchase Program, Drought Risk Reduction Investment Program, and CVPIA Water Acquisition Program) would participate in groundwater substitution actions (three of the four would only occur during dry years). All programs will conduct groundwater actions based on individual environmental documents required for the use of CVP and SWP facilities. The oversight of water transfers by Reclamation and DWR would ensure that the effects because of groundwater substitution actions on wetlands and other vegetation communities would be avoided or minimized. Groundwater substitution actions undertaken by other water supply programs would also be limited by water transfer capacities and the same criteria applied to the EWA program. Therefore, groundwater substitution would not present a cumulative effect on vegetation and wildlife resources.

Three programs (Sacramento Valley Water Management Agreement, Dry Year Purchase Program, and Drought Risk Reduction Investment Program) would include crop idling

as a water acquisition method (during dry years only). As with groundwater substitution, these programs, including EWA, would be limited by water export capacities. These limitations coupled with a 20 percent limitation by EWA agencies for water purchases related to crops idling within a county would control the amount of cropland idled for water supply programs (EWA agencies would limit or not acquire water through crop idling when the cumulative total of all programs is at 20 percent). Therefore, crop idling would not present any cumulative effects on vegetation and wildlife resources.

The purchase of stored reservoir water would potentially occur in all of the cumulative programs. The EWA analysis includes the maximum amount of water available from each reservoir. Therefore, the amount for purchase either by the EWA agencies or in combination with other projects evaluated in this section is the worst-case effect that could occur should all programs purchase stored reservoir water in any single year. Therefore, the analysis in this section can also be used as the cumulative analysis. The effect is considered less than significant.

Groundwater substitution would take place as part of two programs, the Drought Risk Reduction Investment Program and the CVPIA Water Acquisition Program. All actions would be coordinated by Reclamation and DWR transfer programs that will monitor for and address the effects from groundwater substitution actions on wetlands and other vegetation communities would be avoided or minimized. Therefore, groundwater substitution would not present a cumulative effect on vegetation and wildlife resources.

All of the cumulative programs would also contribute to changes in timing and levels of river flows. Water resource and development projects, such as dams and levees, and land uses, such as conversion to agriculture, have had significant effects on the regeneration potential of riparian forests (Strahan 1985). EWA water transfers would potentially exacerbate conditions that are currently unhealthy for riparian forest. However, the EWA program includes a monitoring and adaptive management plan that is tasked with ensuring effects of EWA actions on riparian habitats are either avoided or minimized. Coordination with other programs would also help to reduce potential cumulative effects on riparian habitat.

10.2.11.2 Export Service Area

Two programs, the Drought Risk Reduction Investment Program and the CVPIA Water Acquisition Program, would include crop idling in the Export Service Area. EWA crop idling actions reduce the acreage of this habitat. However, cotton does not provide habitat of value to wildlife; therefore idling of cotton crops under the EWA program would not affect vegetation and wildlife resources. Consequently EWA actions would not contribute to cumulative effects in the Export Service Area through crop idling actions.

EWA is the only program employing source shifting in the EWA Service Area; therefore, there is no cumulative impact to consider for this water management option. Overall, the EWA program would not contribute to cumulative effects on vegetation and wildlife resources.

Chapter 11
Regional and Agricultural Economics

Regional economies are local systems of producing, delivering, and trading goods and services. Agriculture in the Environmental Water Account (EWA) area of analysis is an important element of the local economy. Regional and agricultural economics is concerned with the net effect of all EWA actions on local economies, including agriculture. Economic indicators addressed in this chapter include agricultural net returns, total output, value added, wages and salaries, and employment.

This chapter describes the economic situation in the EWA area of analysis, the National Environmental Policy Act (NEPA) and the California Environmental Quality Act (CEQA) issues, and the economic effects of the No Action/No Project Alternative, the Fixed Purchase Alternative and the Flexible Purchase Alternative.

11.1 Affected Environment/Existing Conditions

The Affected Environment/Existing Conditions section presents recent data related to the economic conditions of the subject areas. First, data are provided for those areas with regional economies affected by crop idling for water transfers. This section presents most data at the county level because data regarding regional and agricultural economics area descriptions are generally available by county. The description of the affected environment does not include the Delta and Southern California portions of the Export Service Area, in which regional agricultural economic effects from EWA crop idling would be unlikely.

Next, this section provides background data related to other economic issues, such as county tax revenue generated by the Williamson Act, agricultural groundwater extraction costs, and water transfer market effects.

11.1.1 Area of Analysis

The Regional and Agricultural Economics area of analysis includes counties in which EWA could acquire water through crop idling. Crop idling would temporarily reduce agricultural production, which could result in regional economic effects. The Upstream from the Delta Region includes Butte, Colusa, Glenn, Placer, Sutter, and Yolo Counties. The Export Service Area includes Fresno, Kern, Kings, and Tulare Counties. The boundaries of each county in each region define the Upstream from the Delta Region and the Export Service Area.

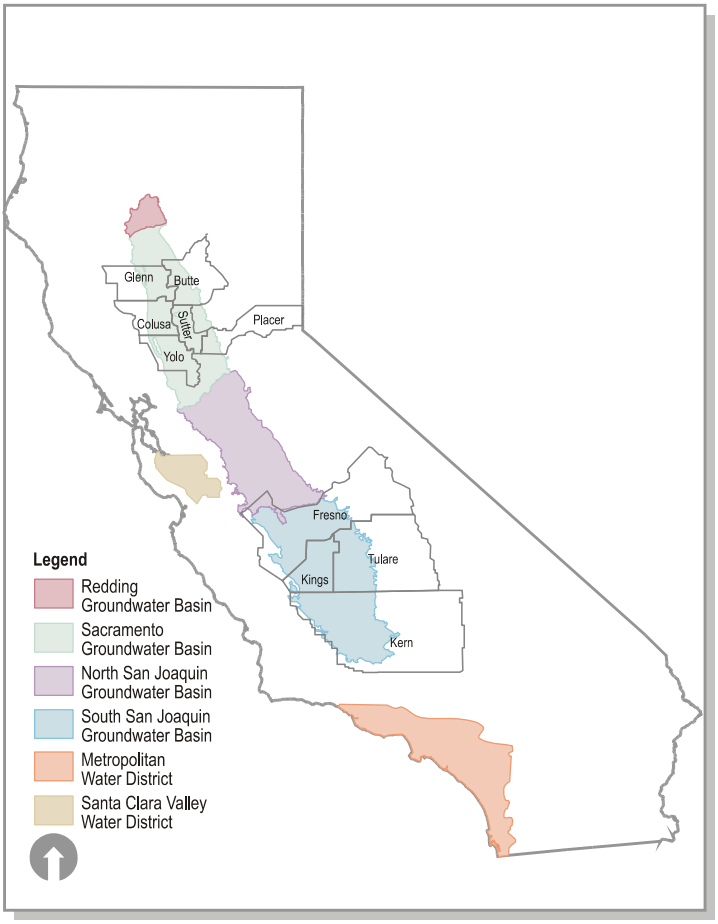

Figure 11-1
Regional and Agricultural Economics Area of Analysis

Agricultural business losses and related effects that could be caused by crop idling would occur in the counties where the EWA agencies purchase water through crop idling. The regional and agricultural economics area of analysis also includes the groundwater resources area of analysis, which extends from the City of Redding in the northern portion of the Sacramento Valley to Kern County in the southern portion of the San Joaquin Valley, because groundwater substitution could increase groundwater extraction costs. The potential for water transfer market effects would be relevant to all EWA regions across California. Figure 11-1 shows the complete area of analysis.

11.1.2 Upstream from the Delta Region

Potentially affected counties in the Upstream from the Delta Region are Butte, Colusa, Sutter, Placer, Glenn, and Yolo Counties. The subsections below first present regional economic data, then economic settings in each potentially affected county within the region. Figure 11-2 displays the Upstream from the Delta Region. Sacramento County is included for reference purposes; Yuba County is included because regional effects of rice idling may affect Yuba County rice-related businesses. Refer to Section 11.2.5.1 for further discussion.

11.1.2.1 Regional Economics

Regional economics data are taken directly from the Bureau of Economic Analysis (BEA) Regional Economic Information System (REIS) 2000. Table 11-1 shows estimated industry earnings and employment for potentially affected counties in the Upstream from the Delta Region. The region's population in 1999 was approximately 773,000, an increase from 665,000 in 1990. In 1999, the Upstream from the Delta Region employed approximately 434,000 people (BEA REIS 2000). Primary employers were services, government, retail trade, and the finance, insurance and real estate sectors. Over time, agriculture, mining, and manufacturing's share of economic

activity in the region has decreased (BEA REIS 2000). This trend is expected to continue in the future.

In Table 11-1, total earnings include wage and salary disbursements, other labor income, and proprietor's net income. In 1999, the largest contributors to total earnings were services, government, and retail trade, at approximately 23.7 percent, 22.5 percent, and 12.4 percent, respectively (BEA REIS 2000). Agriculture, forestry, and fishing provided 1.5 percent, approximately $190 million, of the region's total earnings, yet the percentage varied widely among the counties. In 1999, agriculture contributed 6.6 percent of total earnings in Glenn County, 3.8 percent in Sutter County and 2.6 percent in Yuba County (BEA REIS 2000). These counties have relatively small urban areas and large percentages of their acreage devoted to farmland.

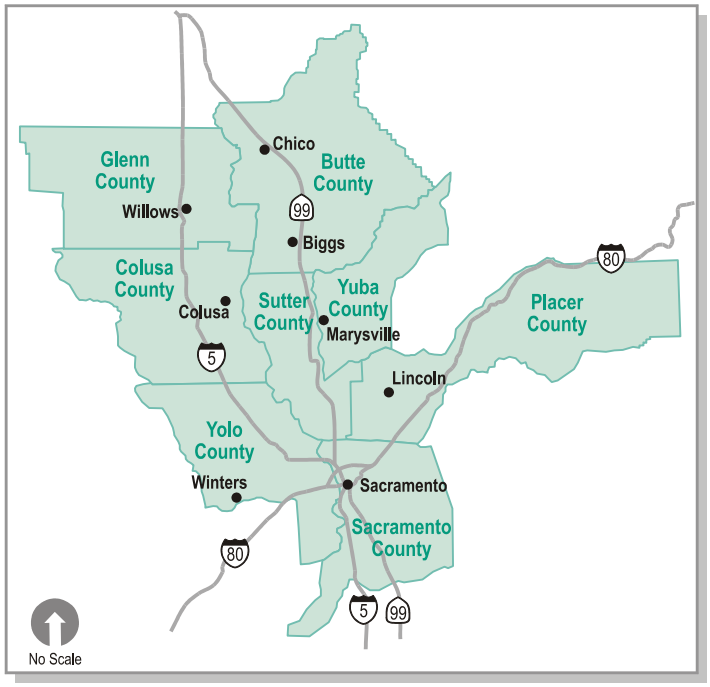

Figure 11-2
Counties in the Upstream from the Delta Region

Table 11-1
1999 Total Industry Earnings and Employment Upstream from the Delta Region [(1)]

	1999 Total Industry Earnings ($1,000)	*1999 Total Industry Employment (jobs)*
Total	$12,674,710	360,183
Agriculture, Forestry, Fishing	$190,403	8,828
Mining	$24,253	695
Construction	$1,140,331	28,749
Manufacturing	$1,544,633	33,288

Services	$3,011,758	73,470
Govt. Enterprise & Special Industry	$2,851,284	71,355

Source: 1999 Bureau of Economic Analysis (BEA) Regional Economic Information System (REIS) Data, Published 2000

(1) Data for Butte, Colusa, Sutter, Placer, Glenn, Yuba, and Yolo Counties, except where noted below. Regional Economic Information System (REIS) data did not include some county estimates to avoid disclosure of confidential information in both industry earnings and employment. Butte estimates are not included in agriculture, forestry and fishing, and mining sectors. Colusa estimates are not included in agriculture, forestry and fishing, and services sectors.

Total personal income is total earnings, adjusted for place of residence,[1] plus dividends, interest and rent, and transfer payments received by the residents. In 1999, total personal income in the region was about $20.7 billion. Total farm personal income in the region was about $552 million (BEA REIS 2000). Table 11-2 shows a summary of economic activity by county in the Upstream from the Delta Region.

Table 11-2
1999 Economic Activity Upstream from the Delta Region $1,000

	Personal Income[1]				Total Industry Earnings[3]	Total Employment[4] (jobs)	Total Population (persons)
County	Total	Non-Farm	Farm	Per Capita (dollars)[2]			
Butte	$4,297,201	$4,247,290	$49,911	$22,012	$2,488,069	98,967	195,220
Colusa	$435,022	$320,040	$114,982	$23,085	$311,180	11,143	18,844
Glenn	$474,298	$448,015	$26,283	$18,015	$291,249	12,406	26,328

Total	$20,730,013	$20,207,425	$522,588		$13,302,273	434,134	773,480

Source: 1999 BEA REIS Data, Published 2000

(1) Personal income is the income that is received by persons from participation in production, from both government and business transfer payments, and from government interest

(2) Per capita personal income is measure of income is calculated as the total personal income of the residents of an area divided by the population of the area. Per capita personal income is often used as an indicator of the economic well-being of the residents of an area.

(3) Total industry earnings include all farm and non-farm earnings.

(4) Total employment includes all industry sector employment estimates of both full and part-time jobs.

11.1.2.2 Agricultural Economics

Numbers and sizes of farms, together with ownership patterns, cropping patterns, production characteristics, and expense characteristics, are used to describe the general structure of agriculture in the region. Table 11-3 provides data on number of farms, land in farms, and amount of cropland for counties in the Upstream from the Delta Region, taken from the United States Department of Agriculture (USDA) Census of Agriculture.

Ownership patterns describe the number of farm owners who live within a region. In 1997, full owners operated about 65 percent of farms or approximately 5,150 farms, and part owners or tenants operated the remaining farms in the counties in the Upstream from the Delta Region (USDA 1999).[2]

In 1997, the average farm size in counties in the Upstream from the Delta Region was 347 acres (USDA 1999).[3] In 1997, the region supported about 1.7 million acres of total cropland, of which 1.4 million acres were irrigated land (USDA 1999).

---

1 The place of residence of individuals is the State and county in which they live.

2 Full owners operated only land they owned. Part owners operated land they owned and also land they rented from others. Tenants operated only land they rented from others or worked on shares for others.

3 USDA data provided assumes the Census Bureau's most recent definition of a farm, being any place from which $1,000 or more of agricultural products were produced or sold, or normally would have been sold during the census year (USDA 1999).

Table 11-3
Farms, Land in Farms and Cropland Profiles of Counties Upstream from the Delta Region, 1997

County	Number of Farms	Land in Farms[1] (acres)	Avg. Size of Farm[2] (acres)	Total Cropland[3]		Harvested Cropland[4]		Irrigated Land[5]	
				Farms[6]	Acres	Farms	Acres	Farms	Acres
Butte	1,942	404,166	208	1,750	247,368	1,646	222,209	1,686	223,690
Colusa	810	430,958	532	759	316,756	722	287,630	723	276,562
Glenn	1,189	482,583	406	1,070	255,968	916	212,848	1,025	220,235
Placer	997	139,597	140	629	62,284	388	28,431	703	34,754
Sutter	1,314	348,349	265	1,259	297,107	1,203	266,399	1,199	242,183
Yolo	923	536,595	581	832	380,700	747	324,291	709	294,021
Yuba	706	208,462	295	548	96,989	426	79,586	556	85,241
Total	7,881	2,550,710	347	6,847	1,657,172	6,048	1,421,394	6,601	1,376,686

Source: 1997 United States Department of Agriculture (USDA) Agricultural Census Data Published 1999

(1) The acreage designated as "land in farms" consists primarily of agricultural land used for crops, pasture, or grazing. All grazing land, except land used under government permits on a per-head basis, was included as " land in farms" provided it was part of a farm or ranch.

(2) All farms were classified into selected size groups according to the total land area in the farm. The land area of a farm is an operating unit concept and includes land owned and operated as well as land rented from others.

(3) This category includes land from which crops were harvested or hay was cut; land in orchards, citrus groves, vineyards, nurseries, and greenhouses; cropland used only for pasture or grazing; land in cover crops, legumes, and soil-improvement grasses; land on which all crops failed; land in cultivated summer fallow; and idle cropland.

(4) This category includes land from which crops were harvested or hay was cut, and land in orchards, citrus groves, Christmas trees, vineyards, nurseries, and greenhouses.

(5) This category includes all land watered by any artificial or controlled means, such as sprinklers, flooding, furrows or ditches, and spreader dikes. Included are supplemental, partial, and preplant irrigation.

(6) Number of farms with some cropland

Cropping patterns are important to both agricultural and regional economics. Crops in the region include rice, other field crops, truck crops, and tree and vine crops. According to California Agricultural Statistics Service (CASS) California Agricultural Commissioners' data report (CASS 2001), in 2000, the Upstream from the Delta Region contributed $765 million to total field crop value of production, including rice, or about 21 percent of the State total. Practically all of the rice, orchards, vegetables, and cotton acreage within the region are irrigated.

Some field crops utilize relatively large amounts of water per acre for irrigation. If idled, rice fields provide the largest amount of water of any of the region's major crops, approximately 3.3 acre-feet per acre (Water Transfers Office 2002).[4]

The Upstream from the Delta Region produces most of the rice grown in California. In 2000, Colusa County had the largest amount of rice acreage in the region and contributed 25.8 percent of the total value of the State's rice production of $618 million (CASS 2001). After Colusa County, the top four counties for rice production in the region were Sutter (20.6 percent of value), Butte (18.2 percent), Glenn (16.6 percent) and Yuba (6.7 percent) (CASS 2001).

---

4 3.3 AF/acre is the estimated ETAW for rice used in the economic analysis (Water Transfers Office 2002). For a definition of ETAW see footnote 11 of this chapter. The estimates of 3.3 acre-feet per acre may be refined in the future as the science for generating these values further develops. Refer to Chapter 2 for more information.

The BEA definition of agricultural net returns is gross crop revenues plus other income less total farming costs. Although higher costs reduce farm profits, some costs represent farm expenditures in the regional economy. In 1999, total cash receipts for the region were approximately $1.5 billion, other income was $0.4 billion, and agricultural net income for the region was estimated to be approximately $232 million (BEA REIS 2000). Table 11-4 shows specific county totals.

Farm production expenses represent income for farm labor, farm supply companies, custom operators, and related businesses. If farm production expenses decrease, then the revenues received by farm labor and businesses also declines. In 1999, total production expenses for the region were about $1.7 billion (Table 11-5). Hired farm labor costs were one of the largest costs reported, accounting for about 32.4 percent of total expenses.

Table 11-4
1999 Agricultural Revenues and Production Costs, Upstream from the Delta Region ($1,000)

	Gross Farm Income[1]							
	Total Cash Receipts			Other Income				
County	Livestock, Production	Crops	Total	Govern-ment Payments	Total Other Income	Total Production Expenses[2]	Realized Net Income[3]	Total Farm Labor and Proprietors Income[4]
Butte	$9,619	$209,466	$219,085	$43,760	$74,101	$286,186	$7,000	$49,911
Colusa	$5,792	$282,188	$287,980	$60,930	$87,327	$308,750	$66,557	$114,982
Glenn	$54,765	$133,319	$188,084	$41,093	$68,456	$251,518	$5,022	$26,283
Placer	$15,744	$24,071	$39,815	$6,824	$12,602	$53,424	-$1,007	$5,771
Sutter	$8,212	$326,740	$334,952	$47,414	$88,374	$330,877	$92,449	$143,413
Yolo	$10,892	$373,020	$383,912	$26,130	$61,196	$374,249	$70,859	$159,021
Yuba	$14,460	$60,127	$74,587	$16,771	$34,809	$117,925	-$8,529	$23,207
Total	$119,484	$1,408,931	$1,528,415	$242,922	$426,865	$1,722,929	$232,351	$522,588

Source: 1999 BEA REIS Data Published 2000

(1) Gross farm income consists of estimates for the following items: cash receipts from marketing of crops and livestock; income from other farm-related activities, including recreational services and the sale of forest products; government payments to farmers; value of food and fuel produced and consumed on farms; gross rental value of farm dwellings; and the value of the net change in the physical volume of farm inventories of crops and livestock.

(2) Production expenses consist of: purchases of feed, livestock, seed, fertilizer and lime, and petroleum products; hired farm labor expenses (including contract labor); and all other production expenses (e.g. depreciation, interest, rent and taxes, and repair and operation of machinery), further broken down in Table 11-5.

(3) Production expenses and gross farm income excluding inventory change are used to calculate realized net income of all farms (gross farm income, excluding inventory change, minus production expenses equals realized net income).

(4) Bureau of Economic Analysis estimate of farm proprietors' income is estimated from modifying realized net income to exclude the income of corporate farms and salaries paid to corporate officers.

Table 11-5
1999 Production Expenses, Upstream from the Delta Region
($1,000)

County	Feed Purchased	Livestock Purchased	Seed Purchased	Fertilizer and Lime	Petroleum Products Purchased	Hired Farm Labor Expenses[1]	Other Production Expenses[2]
Butte	$2,370	$1,165	$8,195	$33,679	$7,767	$102,729	$130,281
Colusa	$1,178	$1,133	$17,283	$38,849	$10,833	$100,003	$139,471
Glenn	$14,897	$6,123	$6,999	$29,495	$7,858	$68,644	$117,502
Placer	$3,785	$1,703	$2,191	$3,878	$1,512	$12,691	$27,664
Sutter	$1,500	$1,001	$11,414	$41,653	$11,436	$107,146	$156,727
Yolo	$1,854	$2,056	$20,373	$46,172	$12,807	$126,149	$164,838
Yuba	$3,699	$862	$2,337	$12,540	$3,406	$41,314	$53,767
Total	$29,283	$14,043	$68,792	$206,266	$55,619	$558,676	$790,250

Source: 1999 BEA REIS Data Published 2000

(1) Hired farm labor includes contract labor.
(2) Other production expenses includes depreciation, interest, rent and taxes, and repair and operation of machinery.

11.1.2.3 County Settings

The regional economic analysis in Section 11.2 describes the economic effects of idling rice fields within selected counties in the Upstream from the Delta Region. The selected counties (Butte, Colusa, Glenn, Placer, Sutter, and Yolo) have extensive rice acreage and water agencies within the counties have shown willingness to participate in the EWA. (See Chapter 2 and Section 11.4.6.1.1.) The following sections describe the existing conditions in these counties. Figure 11-2 shows the general location of the counties within the region.

11.1.2.3.1 Butte County

Butte County is about 60 miles north of Sacramento in California's Central Valley along the Highway 99 corridor and is bordered by the Sacramento River or Butte Creek on the west and the Sierra Nevada Mountains on the east. Historically, Butte County has been an agriculturally based county, and commercial agriculture continues to be the county's principal economic base. Some non-agricultural industry located in Chico provides alternative economic base. Butte County's water supplies include local surface water, the Feather River, and groundwater. The Feather River and groundwater are the largest sources for the county's water demands.

In 1997, Butte County had 1,942 farms on approximately 404,000 acres (USDA 1999). In 1997, farming accounted for 38.5 percent of the county's land area. Butte County's gross value of agricultural production was $291 million in 2000 (CASS 2001).[5] In addition, in 1993, agriculture indirectly contributed an estimated $1 billion annually to the county's economy, as agricultural revenue spent in the county (Butte County 1995). The most valuable crop in Butte County is rice. The county's milled rice, planted on 98,000 acres, generated 18 percent ($112.3 million) of California's gross

[5] The gross value of production includes all farm production, whether sold into usual marketing channels or used on the farm where it is produced. Includes production of field crops, seed crops, vegetable crops, fruit and nut crops, nursery, flowers and foliage, apiary products, livestock, livestock products, poultry and poultry products.

value of agricultural production of rice in 2000 (CASS 2001). Other major crops in the county are almonds, walnuts, and plums. Table 11-6 summarizes the value of production and acreage of Butte County's leading commodities.

Table 11-6
Butte County Leading Commodities, 2000

Commodity	Value of Production ($ Million)	Acreage	Rank Among California Counties
Rice	112.3	98,000	3
Almonds	47.5	36,095	7
Walnuts, English	38.0	18,398	4
Plums, dried	31.1	12,472	2
Peaches, clingstone	7.1	1,933	5

According to Employment Development Department (EDD) labor statistics, the services sector was the largest employer in the county, employing 24.5 percent of the labor force in 2000. Recent growth within the service industry has been in health services and the social services components (EDD 2001a). Aircraft and parts, colleges and universities, and amusement and recreation services are some of the other major employers in the county (EDD 2001a). According to the Department of Finance (DOF) labor statistics, in 2000, agricultural employment was less than 4 percent (3,000 people) of the civilian labor force (DOF 2002). [6] In 2000, Butte County had an unemployment rate of 7 percent (DOF 2002).

11.1.2.3.2 Colusa County

Colusa County is about 35 miles northwest of Sacramento along the I-5 corridor. The coastal ranges border the county on the west side, and Butte Creek or the Sacramento River is the border on the east. The county has a highly agricultural economy. Relative to other California locations, land in Colusa County is inexpensive and high quality water is generally available. Water sources include groundwater, local surface waters, the Sacramento River, and surface water reuse.

Colusa County had 810 farms in 1997, totaling 430,958 acres, or 38.5 percent of the 736,450 total acres in the county (USDA 1999). The gross value of agricultural production in the county was $346 million in 2000 (CASS 2001). Colusa County ranks as the leading rice-producing county in the United States. Colusa County is also the lead producer of field crops in the region, with a total field crop production value of about $195 million in 2000 (CASS 2001). Major field crops include 147,270 acres of rice, 18,900 acres of wheat, 11,600 acres of safflower, 6,250 acres of hay, and 860 acres of

[6] Agricultural employment includes agricultural workers who are employed by farm labor contractors; employment data do not include unpaid family workers.

field corn. A University of California Cooperative Extension (UCCE) profile states that in Colusa County, "there is currently a transition from row crops to perennial crops (almonds, grapes, walnuts) and from low-value agronomic crops to higher value vegetables or other row crops" (UCCE 2002).

Table 11-7 displays the county's major crops and associated value of production, acreage, and rank among California counties.

Table 11-7
Colusa County Leading Commodities, 2000

Commodity	*Value of Production ($ million)*	*Acreage*	*Rank Among California Counties*

N/A – Not available. Acreage for commodity cannot be enumerated

Colusa is primarily a rural agricultural county, with a total population of about 19,000 in 1999 (BEA REIS 2000). In 2000, agricultural employment in Colusa County was 28.8 percent (or 2,540 employees) of total employment, the highest share in the Sacramento Valley (DOF 2002). A little over 19 percent of the workforce was employed in the government sector and 15 percent in retail trade (DOF 2002). Some of the other major employers in the county include trucking and courier services, amusement and recreation services, oil and gas field services, and groceries and related products (EDD 2001a). In 2000, Colusa County had an unemployment rate of 17.6 percent (DOF 2002).

11.1.2.3.3 Glenn County

Glenn County is about 100 miles northwest of Sacramento, along the I-5 corridor. The county includes the western boundary of the Mendocino National Forest and has the Sacramento River as its eastern boundary. Glenn County has a highly agricultural economy. The county has a high quality water supply; groundwater, local surface water and Sacramento River water are the main sources of supply.

Glenn County had 1,189 farms in 1997. In 1999, farmland occupied 57.3 percent, or 482,583 acres of the county's total land area (USDA 1999). In 2000, Glenn County's major commodities were rice, almonds, milk products, prunes and livestock. Table 11-8 presents value of production and acreage of the county's top commodities. The county's gross value of farm production was $280.9 million in 2000. In 2000, field crops produced over $140 million in total value annually. Rice was produced on 87,383 acres and the total production value was over $100 million (CASS 2001).

Table 11-8 Glenn County Leading Commodities, 2000

N/A – Not available. Acreage for commodity cannot be enumerated

Government was the top industry in Glenn County in 2000, employing 22 percent of the county's labor force (DOF 2002). Agriculture employed 14.4 percent (1,520 people) of the work force in Glenn County. Manufacturing jobs, a substantial portion of which are in food processing, constitute 8 percent of local employment in 2000 (DOF 2002). In 2000, Glenn County had an unemployment rate of 12 percent (DOF 2002).

11.1.2.3.4 Placer County

Placer County is about 15 miles northeast of Sacramento along the I-80 corridor. The county encompasses the rim of the Sacramento Valley to the west and the Sierra Nevada Mountains, Lake Tahoe, and the Nevada border to the east. Placer County has urban and agricultural areas and is one of the fastest growing counties in California (EDD 2001). The county's water supply includes surface water and groundwater. A large share of the water supply comes from surface water runoff stored by Nevada ID, PG&E and others (Hutchison 2002).

In 1997, of the 898,820 acres of land within the county, 139,597 acres were occupied by 997 farms. Farmland accounted for 15.5 percent of the total land area. From 1992 to 1999, the number of farms in the county decreased 12 percent (USDA 1999).

Currently, Placer County's major commodities include milled rice, cattle and calves, and nursery products. Table 11-9 presents the top commodities in the county in terms of gross value of production. The county's total gross value of agricultural production in 2000 was $60.5 million (CASS 2001).

Table 11-9 Placer County Leading Commodities, 2000

N/A – Not available. Acreage for commodity cannot be enumerated

In 2000, agricultural employment was less than 3.5 percent (4,000 people) of the civilian workforce in Placer County. In fact, over 50 percent of the workforce was employed in trade and service industries (DOF 2002). Recently an influx of major corporations, including numerous technology firms, has occurred in Placer County. In 2000, the county's unemployment rate was 3.2 percent, lower than that of the State unemployment rate of 4.9 percent (DOF 2002).

11.1.2.3.5 Sutter County

Sutter County is about 40 miles north of Sacramento, along the State Highway 99 corridor, in the Sacramento Valley between the Sacramento and Feather Rivers. The county has a highly agricultural economy. Sutter County's water supply includes surface water from the Feather and Sacramento Rivers, other surface water, surface water reuse, and groundwater wells (Dahlman 2002).

In 1997, there were 1,317 farms occupying 248,349 acres (90.3 percent) of the 385,600 total acres in the county (USDA 1999). The gross value of Sutter County's agriculture production in 2000 was $343.5 million (CASS 2001), 21st in the state. The main commodities in 2000 were rice, dried plums, peaches, and walnuts (see Table 11-10 for other top commodities). In 2000, Sutter County accounted for 20.6 percent of total rice production value (CASS 2001). The county produced approximately $154 million of rice, corn, safflower, hay/alfalfa, wheat and various other field crops. In 2000, rice was planted on a total of 107,704 acres, and corn, safflower, hay, pasture and wheat were on 6,992 acres, 12,914 acres, 6,571 acres, 11,556 acres and 9,003 acres, respectively.

Table 11-10

Approximately 32,100 people were in Sutter County's workforce and the unemployment rate was 13 percent in 2000 (DOF 2002). According to the 1996 General Plan, agriculture and agriculturally related services and industries have dominated employment in the county (Sutter County 1996). In 2000, about 17 percent (6,200 people) of Sutter County's civilian workforce was employed in agriculture. Other major industries in the county were the retail trade and service industries; each employed about 5,400 people in 2000 (DOF 2002).

11.1.2.3.6 Yolo County

Yolo County is immediately west of Sacramento County near the southern end of the Sacramento Valley along the I-80 and I-5 corridors. Bordered by the Vaca Mountains to the west and the Sacramento River to the east, Yolo County encompasses 1,034 square miles (Yolo County 1983). The county has a very agricultural economy except that some urban areas are tied to education facilities and the Sacramento urban economy. Yolo County's water supply includes groundwater and surface water. Important surface waters are the Cache Creek System, which includes Clear Lake, Indian Valley Reservoir, and Cache Creek upstream from the Capay Diversion Dam, and water from the Sacramento River via diversions and drainage channels.

In 1997, Yolo County had 923 farms on approximately 536,595 acres (USDA 1999). Farming accounted for approximately 82.8 percent of the county's land area (USDA 1999). The most valuable crop in Yolo County was tomatoes for processing. In 2000, the county's tomato crops, planted on 48,575 acres, generated about 13 percent ($76.5 million) of California's processing-tomato income (CASS 2001). Within the State, only Fresno County generates more income from tomatoes on more acres. Other major crops in the county are grapes, rice, and hay. Table 11-11 provides data on Yolo County's leading commodities.

Table 11-11 Yolo County Leading Commodities, 2000			
Commodity	**Value of Production ($ million)**	**Acreage**	**Rank Among California Counties**
Tomatoes, Processing	76.5	48,575	2

N/A – Not available. Acreage for commodity cannot be enumerated.

In 2000, the agricultural industry employed about 5,000 people, less than 6 percent of the civilian workforce. Other major industries in the county were state-local government and trade industries, which employed 26,600 and 21,800 people, respectively (DOF 2002). In 2000, Yolo County had an unemployment rate of 4.3 percent (DOF 2002).

11.1.3 Export Service Area

This section describes regional and agricultural economic conditions in Fresno, Kern, Kings, and Tulare Counties of the Export Service Area. This description of the affected environment does not include the Southern California portion of the Export Service Area, in which regional agricultural economic effects from the EWA are unlikely. In Chapter 11, the term "Export Service Area" always means Fresno, Kern, Kings, and Tulare Counties.

Section 11.1.3.2 describes the settings in Fresno, Kern, Kings and Tulare Counties, which are the counties most likely to experience agricultural economic effects as a result of EWA water purchases. These counties are shown in Figure 11-3.

Figure 11-3
Counties in the Export Service Area

11.1.3.1 Regional Setting – Export Service Area

Table 11-12 shows economic variables estimated by industry in the Export Service Area. The regional population in 1999 was approximately 1.8 million (BEA REIS 1999). In 1999, the region employed approximately 823,000 people. Primary employers were services, agriculture/forestry/fisheries, retail trade, services, and government. Employment in agriculture has decreased in recent years. In 1999, the agricultural sector provided about 98,000 jobs (or 11.9 percent of employment) in the region (BEA REIS 2000).

Table 11-12
1999 Total Industry Earnings and Employment in the Export Service Area [1]

	Total Industry Earnings ($1,000)	***Total Industry Employment (jobs)***
Total	**$24,492,217**	**823,222**
Agriculture, Forestry, Fishing	$1,542,613	98,189
Mining	$587,166	9,902
Construction	$1,650,448	45,410

Finance, Insurance, Real Estate	$1,071,016	43,606
Services	$5,495,303	215,425
Govt. Enterprise & Special Industry	$6,510,773	144,859

Source: 1999 BEA REIS Data Published 2000

(1) Data for Fresno, Kern, Kings, and Tulare Counties, except where noted below. REIS data did not include some county estimates for industry earnings and employment by sector to avoid disclosure of confidential information. Kings and Tulare estimates are not included in mining and financial sectors

Total industry earnings for the region were about $24 billion in 1999. Largest contributors to total earnings were government (26.6 percent), services (22.4 percent) and retail trade (10.7 percent). Agriculture, forestry, and fishing provided 6.3 percent, approximately $1.5 billion, of the region's total earnings (BEA REIS 1999). In 1999, the agriculture, forestry and fishing sector in Tulare, Kern, and Fresno Counties provided 7.4 percent, 5.8 percent and 5.3 percent of county industry earnings, respectively. Average per capita income for the region was $19,023 (BEA REIS 2000). Table 11-13 summarizes economic activity by county in the Export Service Area.

Table 11-13
1999 Economic Activity in the Export Service Area, $1,000

County	Personal Income				Total Industry Earnings[1]	Total Employment[2] (jobs)	Total Population (persons)
	Total	Nonfarm	Farm	Per Capita (dollars)			
Fresno	$16,135,625	$15,496,060	$639,565	$21,146	$11,307,494	406,823	763,069

Source: 1997 USDA Data, Published 1999

Refer to Table 11-3 for definitions of terms

In 1997, the average farm size in counties in the Export Service Area was 641 acres. In 1997, the region supported about 3.5 million acres of total cropland, of which 3.1 million acres were irrigated land (USDA 1999). Ownership patterns describe the number of farm owners who live within a region. In 1997, full owners operated about 73 percent of farms or approximately 11,014 farms, and part owners or tenants operate the remaining farms in the counties in the Export Service Area (USDA 1999).

As measured by harvested acres, cotton was the number one crop in the Export Service Area. In 2000, Fresno contributed 34.0 percent of the total $905 million production value of cotton lint in the State, while Kings and Kern supplied 21.8 percent and 21.4 percent, respectively (CASS 2001). Other important crops in the region, as measured by value of production, were other field crops, orchards, grapes, and alfalfa.

In 2000, the Export Service Area accounted for 39 percent of the State's livestock production value, about 41 percent of fruit and tree-nuts value, and about 43 percent of field crop value (CASS 2001). In 1999, total agricultural cash receipts for the region were about $7.6 billion. Including other income and government payments, agricultural income for the region was estimated at $8.2 billion. Production expenses were about $7.6 billion in 1999, leaving a net cash return of $0.6 million (BEA REIS 2000). Hired and contract labor was the largest expense reported, accounting for

about 31 percent of total expenses (BEA REIS 2000). Tables 11-15 and 11-16 summarize farm income and production expenditures by county in the Export Service Area.

Table 11-15
1999 Agricultural Revenues and Production Costs, Export Service Area
($1,000)

11.1.3.3 County Settings

The regional economic analysis in Section 11.2 evaluates the economic effects of idling cotton fields within selected counties in the Export Service Area. The counties (Fresno, Kern, Kings, and Tulare) have extensive cotton acreage, and water agencies within the counties have shown willingness to participate in the EWA. (Refer to Chapter 2.) The following section describes the existing conditions in these counties.

11.1.3.3.1 Fresno County

Fresno County is in the central San Joaquin Valley. The Sierra Nevada rises out of the low foothills on the county's eastern boundary, and the county's western border extends into the Diablo Mountains (EDD 2001a). The valley floor between is 50 to 60 miles wide and contains some of the most productive agricultural land in the country. The county's economy is highly agricultural except that some urban areas such as Fresno have a more diverse economic base. Fresno County agriculture relies on local surface water, groundwater, and CVP contracts for most of its surface water supply. The groundwater basin below the county is an important water supply.

In 1997, Fresno County had 6,592 farms encompassing 1,881,418 acres (49.3 percent of total county acres). The average size of farms increased 13 percent from 253 acres in

1992 to 285 acres in 1997 (USDA 1999). Irrigated acreage in 1997 was 1,538,812 acres (USDA 1999).

With extensive acreage and intensive agriculture, Fresno County had the largest dollar value of agricultural production in the State, $3.41 billion, in 2000 (EDD 2001a). In 2000, fruit and nut crops contributed $1.24 billion to total value, and field crops contributed $507 million (CASS 2001). Cotton was valued at $354 million, a 6.61 percent increase from 1999 (Fresno County Agricultural Commissioner's Office 2001). Grapes have been the leading crop for over twenty years. In 2000, the value of grapes reached $642 million, about 18.7 percent of the county's total production value (CASS 2001). Table 11-17 shows the leading commodities by value and acreage.

Table 11-17
Fresno County Leading Commodities, 2000

Commodity	Value of Production ($ million)	Acreage	Rank Among California Counties
Grapes	642.3	225,276	1
Poultry	400.0	N/A	1

Peaches	95.1	13,953	1

Source: County Agricultural Commissioners Report 2001

N/A – Not available. Acreage for commodity cannot be enumerated

In 2000, Fresno County had an unemployment rate of 14.3 percent (DOF 2002). High unemployment is a result of seasonal variations in the demand for farm labor (EDD 2001a). The agricultural industry employed 77,500, or 20 percent of the civilian labor force, in 2000 (DOF 2002). Other major employers in the county include colleges and universities, hospitals, poultry and eggs, and department stores (EDD 2001a).

11.1.3.3.2 Kern County

Kern County is on the south end of the San Joaquin Valley and is bordered by the Temblor Mountain Range along the county's western boundary, the Tehachapi Mountains on the south and the Sierra Nevada Mountains to the east. About one-third of the county is within the valley floor of the San Joaquin Valley. Kern County is the third largest county in California in land area (EDD 2001a). The counties' economy is agricultural except that transportation, petroleum and some urban areas provide other economic base. Water sources include local and imported surface water and groundwater.

Kern County contributed approximately $2.2 billion to the gross value of agricultural production, ranking it number four in the State in 2000 (CASS 2001). Kern County relies heavily on groundwater for agricultural uses; however, some water agencies

have SWP and CVP water supplies. Irrigated acreage in 1998 was 861,900 acres (Kern County Water Agency 2002).

In 1997, Kern County had 1,997 farms encompassing over 2.8 million acres (USDA 1999). Farmland made up 54.7 percent of the 5.2 million acres in the county. The average farm size was 1,428 acres (USDA 1999).

Kern County ranks in the top five agricultural counties in the United States (EDD 2001a). In 1990, cotton was the county's most valuable crop with a production value of about $352 million (Kern County Agriculture Commissioner's Office 1991). In 1993, grapes replaced cotton as the most valuable crop. Citrus became the second highest value crop in 1997 because of increased prices and more acreage in production (Kern County Agriculture Commissioner's Office 1998). Over time, Kern County has shown a decrease in cotton acreage and an increase in permanent crop acreage.

In 2000, Kern County's top five commodities, grapes, citrus, cotton, milk and almonds, accounted for 57 percent of Kern County's total value of production. Table 11-18 shows the leading commodities by value and acreage.

Table 11-18
Kern County Leading Commodities, 2000

Commodity	*Value of Production ($ million)*	*Acreage*	*Rank Among California Counties*
Grapes	438.3	85,971	2
Citrus, Fresh and Processing	291.1	41,405	2
Cotton, including Seed	226.0	196,075	3
Milk, Marketing and Manufacturing	156.3	N/A	5
Almonds	142.2	82,572	1
Pistachios	124.0	29,077	1
Nursery Crops	106.2	3,440	10
Hay, Alfalfa	91.2	129,000	2
Potatoes, Fresh and Processing	78.7	20,390	1
Cattle and Calves	55.9	N/A	6

In 2000, Kern County's work force was about 287,000 people. Agriculture was the third largest employer for Kern County in 2000, following government (18.0 percent) and services (17.1 percent) (EDD 2001). Agriculture provided 16.3 percent of total employment with approximately 46,900 jobs (DOF 2002). The agricultural industry increased by 2000 jobs in the year 2000 (EDD 2001). Other major employers in the county include hospitals, schools, groceries and related products, and public administration (EDD 2001). In 2000, the county had a relatively high unemployment rate of 11.3 percent (DOF 2002).

11.1.3.3.3 Kings County

Kings County is in the southern half of the San Joaquin Valley, north of Kern County. The county is the smallest of the Export Service Area counties considered in the analysis. Its borders are the Kings River and the Kettle Hills to the southwest (EDD

2001a). The county is composed mainly of level farmland, crossed by the California Aqueduct and a number of other irrigation waterways. The economy is very agricultural. Kings County relies heavily on groundwater and local surface water supply.

In 1997, 421,365 irrigated acres represented approximately 70 percent of total land in farms (USDA 1999). In 1997, of the total 897,280 county acres, 617,030 acres, about 68.7 percent, was devoted to farmland. In 1997, there were 1,079 farms (USDA 1999). With double cropping, field crops accounted for 641,117 total harvested acres and fruit and nut crops were planted on 30,634 acres.

In 2000, Kings County was ranked 12th in the state in total agricultural production with a gross value of $885 million, a 1.8 percent decrease from the all time high level set in 1999 (Kings County Agricultural Commissioner's Office 2000). The value of field crops increased by about $22 million from 1999 to 2000 and vegetable crop value increased $10 million (Kings County Agricultural Commissioner's Office 2001). The top five commodities in 2000 in the county were milk, cotton, cattle and calves, alfalfa and hay, and turkeys. Total milk value was approximately $292 million and total cotton value was $232 million (CASS 2001). Kings County produces upland and pima cotton varieties, 113,106 acres and 86,494 acres, respectively. Table 11-19 shows the leading commodities by value and acreage.

Table 11-19
Kings County Leading Commodities, 2000

Commodity	*Value of Production ($ million)*	*Acreage*	*Rank Among California Counties*
Milk, Market	291.8	N/A	5
Cotton Lint, Upland	111.7	113,106	3
Cotton Lint, Pima	85.9	86,494	1
Cattle and Calves	62.6	N/A	3
Cottonseed	34.4	9,265	4
Hay, Alfalfa	33.9	53,710	8
Turkeys	30.4	N/A	3

N/A – Not available. Acreage for commodity cannot be enumerated

In 2000, Kings County had an unemployment rate of 13.9 percent (DOF 2002). In 2000, agriculture was the second largest employer in the county, employing 7,710 or 16.8 percent of the civilian labor force (DOF 2002). Government was by far the largest industry, employing 27 percent of the labor force. The service industry was the third largest employer (DOF 2002). Other major employers in the county include public administration, hospitals, and preserved fruits and vegetables (EDD 2001a).

11.1.3.3.4 Tulare County

Tulare County is north of Kern County. The Sierra Nevada range dominates the eastern portion of the county, while extensively cultivated lands on the valley floor are the major features of the western half. Almost half the county's 3.1 million acres is devoted to national parks and forests, including Sequoia and Kings Canyon National Parks and Inyo and Sequoia National Forests (EDD 2001). The economy is very agricultural except that some transportation and urban economic base is located along the Highway 99 corridor. Tulare County relies on groundwater, local surface water, and SWP and CVP imported water for irrigation.

In 1997, Tulare County had 5,446 farms encompassing over 1.3 million acres (USDA 1999). Farming represented about 42.4 percent of total county land area. Acres in cotton have decreased approximately 35 percent since 1987, while land in orchards has increased 14 percent (USDA 1999).

In 2000, Tulare County was the second highest-ranking county in California in gross value of agricultural production, at over $3 billion (CASS 2001). Fruit and nut crops accounted for $1.3 billion of the total value. Livestock and poultry products had a production value of $8.7 million in 2000. The top five commodities in 2000, milk, oranges, grapes, cattle and calves, and plums, accounted for 71.5 percent of Tulare County's total production. Cotton had a production value of $84 million (CASS 2001). Table 11-20 shows the leading commodities by value and acreage.

Table 11-20
Tulare County Leading Commodities, 2000

Commodity	*Value of Production ($ million)*	*Acreage*	*Rank Among California Counties*
Milk	857.2	N/A	1
Oranges, Navel and Valencia	451.2	104,751	1
Grapes	419.0	78,264	3
Cattle and Calves	375.2	N/A	1
Plums	91.5	18,054	2
Cotton Lint and Seed	84.0	79,410	4
Hay and Silage, Alfalfa	78.6	92,888	3

N/A – Not available. Acreage for commodity cannot be enumerated

In 2000, agriculture employed approximately 35,500 persons, almost 21 percent of total employment (DOF 2002). Dairy products, schools, and hospitals are other major employers in the county. In addition to substantial packing/shipping operations, light and medium manufacturing plants are increasing in number and becoming an important factor in the county's total economy (EDD 2001a). In 2000, the unemployment rate was 15.4 percent (DOF 2002).

11.1.4 Property Tax Revenue

The affected environment for property tax revenues includes those counties that might participate in EWA water acquisition by idling irrigated land for water transfers.

The California Legislature passed the Williamson Act in 1965 to preserve open space and agricultural lands by discouraging premature and unnecessary conversion to urban use. The Williamson Act authorizes local governments and property owners to voluntarily enter into contracts to commit land to specified uses for 10 years or more. Once the land is enrolled, it is valued at a reduced rate for property tax purposes pursuant to valuation laws. Chapter 13, Table 13-1 shows acreage enrolled in the Williamson Act.

The Open Space Subvention Act provides partial replacement of local property tax revenues foregone as a result of participation in the Williamson Act. The Open Space Subvention Act allows the State to pay counties $5 per acre for prime agricultural land and $1 per acre for all other agricultural land that participates in the Williamson Act.[7] One condition for prime land classification under the Williamson Act is that the land has produced a gross crop value of not less than two hundred dollars ($200) per acre for 3 of the previous 5 years. If farmers idle a parcel of Prime land for any 3 out of 5 years, the State could reclassify that parcel to a lower level and the county could lose $4 per acre of Open Space Subvention Act revenues.

Table 11-21 summarizes total property tax revenues and Open Space tax relief payments the county governments received during Fiscal Year 1999 to 2000.

---

[7] Prime agricultural land under the Williamson Act means any of the following:

- All land that qualifies for rating as class I or class II in the Natural Resource Conservation Service land use capability classifications.
- Land which qualifies for rating 80 through 100 in the Storie Index Rating.
- Land which supports livestock used for the production of food and fiber and which has an annual carrying capacity equivalent to at least one animal unit per acre as defined by the United States Department of Agriculture.
- Land planted with fruit- or nut-bearing trees, vines, bushes, or crops which have a nonbearing period of less than 5 years and which will normally return during the commercial bearing period on an annual basis from the production of unprocessed agricultural plant production not less than $200 per acre.
- Land which has returned from the production of unprocessed agricultural plant products an annual gross value of not less than two hundred dollars ($200) per acre for 3 of the previous 5 years.

Table 11-21 County Property Tax Revenues and Open Space Tax Relief Aid, Fiscal Year 1999-2000, Dollars		
County	**Total Property Tax**	**Open Space Tax Relief Payment**
Butte	$13,431,708	$642,887
Colusa	$4,888,116	$584,299
Glenn	$3,293,736	$710,593
Placer	$45,963,637	$100,249
Sutter	$8,040,433	----
Yolo	$11,665,837	$1,148,612
Fresno	$70,008,544	$5,813,928
Kern	$110,870,978	$5,194,660
Kings	$11,135,985	$2,833,900
Tulare	$30,221,403	$3,519,857

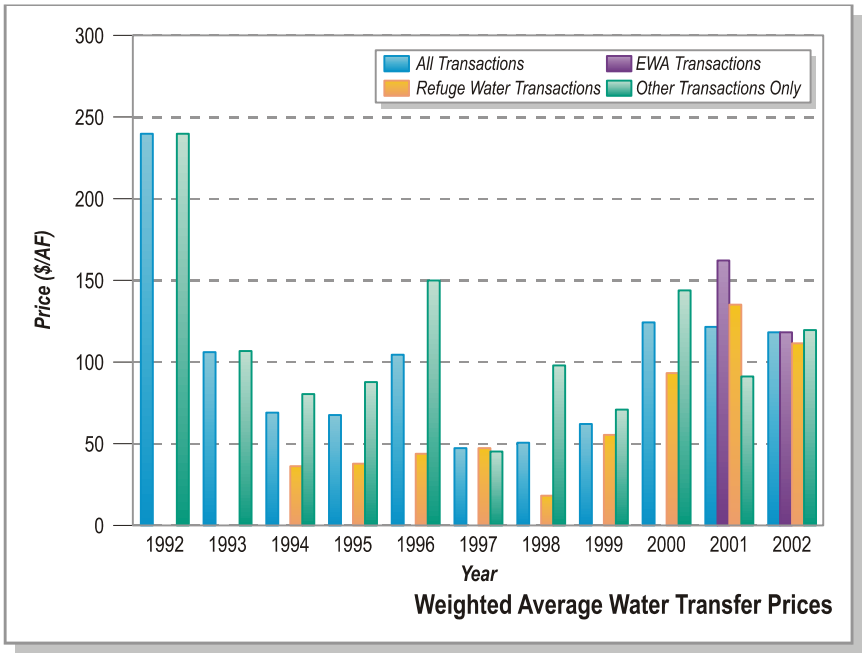
11.1.5 Groundwater Pumping Costs

The affected environment for groundwater pumping costs includes all counties overlying groundwater basins with potential EWA actions. Within this region, groundwater costs could be potentially affected anywhere that groundwater users participate in groundwater substitution transfers.

Agricultural groundwater costs vary considerably throughout California. Many factors influence these costs, including depth to groundwater, pump efficiencies, and power costs. The California Water Plan Update presents a range of averages for agricultural groundwater costs for the hydrologic regions, which are summarized in Table 11-22. Groundwater pumping costs tend to increase during drought as more water is pumped and average depth to water increases.

Table 11-22 Typical Agricultural Groundwater Production Costs in 1992 by Hydrologic Region	
Region	**Groundwater Costs ($/acre-foot)**
Sacramento River	30-60
San Joaquin	30-40
Tulare Lake	40-80



Source: DWR 1993
The range represents the average cost a specific locations within a region, and includes capital, operations, and maintenance and replacement costs.

11.1.6 Water Transfer Market Effects

The affected environment for water transfer market effects includes all EWA regions across California. This area includes the State and Federal Project service areas and areas that could be affected by exchange of water.

A CALFED program objective is to develop a water market that effectively transfers water from willing sellers to buyers, while protecting third-party water users and the environment (CALFED 2001). The water transfers market has grown markedly in the past years. The Public Policy Institute of California (PPIC) estimated that the total volume of water transfers in California has recently ranged from 0.5 acre-foot to 1.2

million acre-feet annually. (PPIC 2002, see Table 11-40.) Figure 11-4 shows prices of major water transfers from 1992 to 2002. The prices have varied over time, and statistical analysis suggests that a trend in the prices over time does not exist.

Sources: Stratecon, Inc. 1992-2003, Water Transfers Office 2003 and 2003a, USBR 2003

Figure 11-4
Weighted Average Prices of Major Water Transfers 1992-2002

The wide variation in prices may be caused by differences in location of the transfers, types of buyers and sellers, timing of availability, water quality, and variation in demand and supply conditions. Also, prices for water transfers may reflect individual negotiations between buyers and sellers rather than competitive market prices.

Factors affecting demand include hydrologic conditions, institutional factors, and agricultural prices. If hydrologic conditions are dry, the price of water transfers typically increases. This premise is supported by Figure 11-4. Prices appear to be higher during 1992, 2001, and 2002, all years which were classified as "dry" under the Sacramento Valley Index (CDEC 2002). When conditions were wet, as in 1995 through 1999, there is more supply and less demand for water transfers, and prices are generally lower. Institutional factors include changes in water allocation caused by changes in laws, regulations and court decisions. For example, recent decisions regarding Colorado River supplies have affected the demand for water transfers to Southern California.

Higher agricultural prices should both increase demand for water transfers and reduce their supply. If agricultural prices are low, more farmers should be willing to participate in water transfers and sell their irrigation water, thereby decreasing the price. According to California Department of Food and Agriculture (CDFA) Resource Directory (2002), upland cotton prices in 1996 were estimated at $0.82 per pound. In 1998, value of rice was estimated at $0.0919 per pound (CDFA 2002). In 2001, the minimum price received by farmers participating in Federal programs was $0.5192 per pound for cotton and $0.065 per pound for rice, both much lower than mid-1990s

levels. These lower crop prices probably increased the willingness of cotton and rice farmers to participate in water transfers in the early 2000s.

11.2 Environmental Consequences/Environmental Impacts

This section describes the effects of EWA actions related to economics. First, section 11.2.1 discusses regulatory requirements for reporting and analyzing economic effects. Then, section 11.2.2 describes assessment methods. Section 11.2.3 describes how economic considerations are being incorporated into the EWA program. Finally, economic effects of the No Action/ No Project, Flexible Purchase Alternative, and Fixed Purchase Alternative are discussed. The analyses first discuss crop idling effects, followed by property tax effects, groundwater cost effects and water transfer market effects. The section ends with a discussion of potential cumulative effects.

11.2.1 NEPA/CEQA Issues

Social and economic changes resulting from a project are addressed somewhat differently under CEQA than under NEPA. CEQA does not consider economic or social changes resulting from a project as adverse effects on the environment. If a physical change in the environment is caused by economic or social effects, the physical change may be regarded as an adverse effect. Because the economic effects of EWA actions do not change the physical environment, a CEQA analysis is not necessary or included in this chapter.

Additionally, under CEQA, the economic or social effect of a project may be used to determine the significance of physical changes caused by the project. For example, economic effects of crop idling could be used to help judge the significance of land use changes. However, the land use effects analysis considers EWA crop idling actions to be less than significant because they do not result in permanent changes to the land use. (Refer to Chapter 13 for further discussion.) Therefore, economic effects are not needed to judge the significance of land use changes.

Under NEPA, economic or social effects must be discussed if they are inter-related to the natural or physical environmental effects of a project. Since economic effects of the EWA are related to physical environmental effects, a NEPA analysis is required. However, NEPA does not require that economic impacts be judged for significance. Therefore, this chapter provides a description of economic effects but does not attempt to determine significance of any economic effects.

In any alternative, the EWA agencies would be responsive to local environmental, economic, and social concerns. The EWA program will include a number of actions to avoid and reduce adverse economic effects. Section 11.2.3 describes these actions.

11.2.2 Assessment Methods

Under each alternative, the EWA Project Agencies would negotiate contracts with willing sellers based on a number of factors including price, water availability, and

location. The EWA Project Agencies may choose to vary their acquisition strategy each year as these factors and others change. Crop idling would occur primarily in dry years in the Upstream from the Delta Region, and primarily in the Export Service Area in wetter years. Other programs would seek crop idling transfers upstream in dry years as well. (Refer to Section 11.2.8.)

To provide a maximum effects analysis, this chapter includes a high level of potential transfers even though the EWA Project Agencies would not likely transfer this much water in a given year. Chapter 2 defines the transfers that are included in the analysis. EWA acquisitions through crop idling and groundwater substitution, purchase, or storage could result in economic effects in the Upstream from the Delta Region and the Export Service Area. In general, any EWA water acquisition could affect market prices for water transfers. The subsections below describe how potential economic effects of crop idling, groundwater acquisitions, and potential changes in water transfer market prices were evaluated.

11.2.2.1 Crop Idling

In crop idling acquisitions, participating farmland owners would voluntarily cease irrigation of rice or cotton for a crop season and transfer the unused irrigation water to the EWA. The EWA Project Agencies would only idle irrigated land by mutual agreement with willing sellers. Economic effects would occur only to the extent that water is obtained by crop idling. (See Section 11.2.7 Comparative Analysis for discussion of crop idling actions during wet and dry years.)

Several institutional issues must be overcome to idle cropland for water transfers. (Refer to Chapter 2 for further discussion.) This document assumes that the EWA agencies and potential sellers can overcome these institutional obstacles and that crop idling would be a viable source of water for the EWA.

The adverse effects of crop idling occur because of trade linkages between irrigated production, use of farm inputs, production of farm outputs, and regional economies. Many businesses trade with farmers. Farmers buy inputs from farm stores, equipment supply stores, custom operators, and other farmers; other regional businesses earn their income by transporting, storing, marketing, and processing agricultural products. Idling of crop land reduces the volume of sales for these businesses. These types of effects are often referred to as third-party economic effects.

DWR (2002) suggests that an analysis of third party effects consider the following: the size of the local economy, its dependence on local agriculture, the pre-existing amount of land idling, the amount of normal variation in idling and the agricultural economy, and self-mitigating conditions such as opportunities for re-employment. The EWA agencies consider some of these factors when making land idling acquisitions in order to avoid or decrease adverse effects. (See Section 11.2.3.)

Effects of idling land are typically a small percentage of a large regional economy when the region includes large urban areas such as Sacramento or Stockton. Use of economic data from large regions as a baseline tends to mask the effects of land idling on individual counties or small rural communities. An effect that appears very small relative to an entire economy may seem quite adverse within the most affected areas. Economic effects of crop idling tend to be concentrated within small subgroups of the regional economy; for example, certain agricultural interests in certain locales within a county. At one extreme, if one job were lost, that job loss could be a very adverse effect for one person. A baseline for comparison of adverse effects should, therefore, be based on the smallest possible regional economies.

This analysis describes economic effects at three levels: the regional level, the county level, and the local level. The regional and county-level analyses can use the economic methodology, and baseline acreage and economic data are available for comparison; however, economic methodology and baseline economic data for rural towns and local industries are not available.

The regional and county economic analysis for this document uses a model based on IMPLAN, an input-output (IO) database and modeling routine, with information from recent University of California Cooperative Extension crop budgets for rice and cotton.[8] The analysis estimates the direct agricultural effects of land idling using the crop budget information and estimates indirect and induced effects in individual counties or aggregations of counties with IMPLAN.[9] Indirect effects are caused by expenditures in the region by regional industries, and include purchases of inputs to grow crops and make products. Induced effects are caused by expenditure of household income. The rest of this chapter refers to this model as the Department of Water Resource's Economic Model for Temporary Idling of Irrigated Land (DEIM).

IMPLAN can apply IO models for any county or group of counties. There is no readily available method for developing IO information for local economies within counties. Therefore, the analysis includes a qualitative discussion of economic effects on local economies.

---

[8] IMPLAN data were in 1997 dollars. Agricultural input data were adjusted to 1997 levels using the GDP price deflator index.

[9] The regional input-output analysis for this assessment uses detailed UCCE crop budgets to correct for three deficiencies of the IMPLAN data and methods.

- IMPLAN expenditure estimates are based on aggregated crop categories and may not be accurate for individual California crops. This analysis uses the crop budgets, not IMPLAN, to estimate the direct farm expenditure, farm labor income, and employment losses.
- Input-output analysis presumes that all inputs change in fixed proportions to output. Idling does not reduce certain fixed inputs. Therefore, this economic analysis uses changes in variable expenditures from the crop budgets as input to the model.
- Input-output analysis does not automatically count impacts from forward linkages (marketing, transportation, storage, and processing of farm production). This assessment uses data from several sources to estimate direct effects associated with rice milling, storage, and transportation (DWR 2002). Forward linkages for the cotton analysis did not need to be added. Farm costs and revenues carry cotton to the point where it leaves the cotton gin, which is believed to be enough expenditure to fairly represent direct effects in the county (DWR 2002).

The method of combining IMPLAN and crop budget information is described by DWR (2002). Refer to Attachment 1 for further discussion of IMPLAN.

11.2.2.2 Property Tax Revenues

Property tax revenues are determined by property values, tax rates, and the Williamson Act and Open Space Subvention Act. Water transfers could have effects on property values and tax revenues in ways that are not easily measured by IO-type models. Therefore, this analysis handles tax revenue effects qualitatively.

11.2.2.3 Groundwater Pumping Costs

Section 11.2.5.4 briefly addresses potential effects of costs associated with EWA groundwater actions. The EWA Project Agencies may acquire water through various groundwater actions, including groundwater substitution, and groundwater purchase. These EWA groundwater actions, as described in the project description, could lead to diminished groundwater levels which may adversely affect costs associated with groundwater extraction. EWA groundwater storage could increase groundwater levels which could lead to lower extraction costs for nearby groundwater users. Economic effects would occur only to the extent that water is obtained by groundwater substitution.

In general, energy costs for pumping, operations and maintenance, and well development are the main components of the costs associated with groundwater extractions. Pumping costs are directly related to the depth of groundwater tables. If groundwater tables decline, more energy is required for pumping, increasing costs.

11.2.2.4 Water Transfers Market Effects

The objective of the water transfers market analysis is to evaluate the effect of EWA participation in the water market on water transfer prices. The analysis of the water transfers market is generally qualitative. The assessment evaluates factors affecting demand and supply in the market for water transfers. Section 11.2.5.5 discusses how the EWA might affect prices in water transfer markets in California.

11.2.3 Environmental Measures Incorporated into the Project

Most of the adverse economic effects of crop idling occur because of trade linkages between irrigated production and regional economies. Many businesses trade with farmers. Farmers buy inputs from farm stores, equipment supply stores, custom operators, and other farmers; other regional businesses earn their income by transporting, storing, marketing and processing agricultural products. Idling of crop land reduces the volume of this business.

In order to avoid or decrease third-party economic effects, the EWA would incorporate the following measures as part of the program definition.

1. EWA agencies would not purchase water via crop idling if more than 20 percent of recent harvested rice or cotton acreage in the county would be idled through EWA water acquisitions. (Refer to Section 11.2.8 for discussion of additional water acquisition programs. The EWA would idle less than 20 percent if other reasonably foreseeable transfers under other programs are idling land.)

To determine the recent harvested acreage, the EWA Project Agencies would consider the number of acres of rice and cotton harvested in each county during the 5 years previous to the transfer. If, in the year immediately prior to the transfer, harvested acreage in each county was within 5 percent of the mean harvested acreage of the county of all 5 previous years, then the amount of rice or cotton acres harvested in the prior year would be used to determine the basis for 20 percent crop acreage. If acres harvested during the year immediately prior to the transfer were not within 5 percent of the mean, then the calculated mean would be used to determine the basis for 20 percent crop acreage.

EWA Project Agencies would gather accurate data regarding the amount of crop acreage previously harvested and idled in participating counties. The data are available from DWR Land Use Surveys, the USDA, and county crop reports. This information would be confirmed by the local Farm Bureau, local UCCE offices, the Agricultural Commissioners Office, or other crop-specific authorities.

Refer to Section 11.2.3.1 for further explanation of the 20 percent crop idling measure incorporated into the project.

2. EWA agencies would also acquire less water by crop idling when the level of land idling is already larger than historically normal.

   Economic effects are related to background conditions as well as the amount of land idling. One of these conditions is the amount of land idling caused by other factors such as drought, low agricultural prices, or other water transfers. The negative economic effects of land idling are exacerbated when an unusual amount of land is already being idled. Therefore, idling less land in a local area when the amount of land idling is already more than historically normal would lessen economic effects.[10] Refer to Section 11.2.8 for discussion of additional water acquisition programs.

11.2.3.1 Considerations Regarding Socioeconomic Effects

EWA agencies incorporated the 20 percent crop idling measure into the project to reduce potential effects on the regional and agricultural economies. Water Code Section 1745.05(b) and the large variation in historical acreage and the intentional, voluntary fallow from Federal farm programs suggest precedent for the 20 percent crop idling measure.

Water Code Section 1745.05 (b) requires a public hearing under some circumstances where the amount of water made available for land idling exceeds 20 percent of the water that would have been applied or stored absent the water transfer. Presumably, third parties would be able to attend the hearing and could argue to limit the transfer based on its economic effects.

---

[10] The local area is defined as a small local economy consisting of a town and closely allied outlying residences and businesses.

The agricultural industry experiences normal variation in crop acreages and agricultural economies are adapted to address this variation. Table 11-23 shows cotton and rice acreage in counties of interest from 1990 to 2000.

Table 11-23 shows that both cotton and rice acreage is quite variable. For both crops, the standard deviation of acreage is about 15 percent of the average. As of 2000, cotton acreage had been below average for 3 years. This trend probably reflects poor cotton prices in these years. For rice, acreage in the 4 years before 1994 was considerably less than average. The lower acreage was probably caused by drought, by DWR's Drought Water Bank, and by rice acreage reduction provisions in these years. Since 1994 there has been relatively little variation in rice acreage. If the effects of idling rice and cotton can be judged by historical precedent in the 1980s and early 1990s, then there is much precedent for land idling up to 15 percent of acreage historically used for these crops.

Table 11-23
Acreage of Cotton and Rice in Counties of Interest, 1990 to 2000

Year	Cotton		Rice	
	1000 acres	*Difference from Mean*	*1000 acres*	*Difference from Mean*
1990	1,071	115	342	-71
1991	948	-9	292	-121
1992	1,023	67	342	-71
1993	1,055	99	387	-26
1994	1,057	100	445	32
1995	1,134	178	432	19
1996	1,058	101	447	34
1997	942	-14	460	47

Counties of interest for cotton are Fresno, Kern, Kings, and Tulare. For rice acreage, includes Butte, Colusa, Glenn, Placer, Sutter, and Yolo Counties. Acreage does not include acreage for seed.

Acreage reduction provisions (ARPs) under Federal farm programs were an important cause of intentional idling of rice and cotton before 1991. These provisions required participating farmers to idle a given share of their rice or cotton land in order to receive program benefits. Historically, about 50 to 75 percent of cotton acreage and 95 percent of rice acreage participated in the programs (Mann and Moore 1993). The mandatory acreage reduction for rice was 20 percent or more in every year from 1984 to 1990, reaching 35 percent in 1986 and 1987 (Green 1990). For cotton, the ARP was 20 percent or more in every year from 1983 to 1990 except 1988 and 1990 (12.5 percent

in both years). With voluntary acreage reduction provisions and improved market conditions, the ARPs were reduced after 1991. The 1996 Farm Bill (the Federal Agriculture Improvement and Reform Act) eliminated the ARPs entirely. However, the large, voluntary acreage reduction established under the ARPs created a precedent to idle up to 20 percent of rice and cotton.

This analysis only describes the economic effects of idling 20 percent of rice and cotton acreage in the identified counties. CEQA and NEPA do not require this analysis to make a judgment on adverse effects relative to a specific threshold. Several other studies have, however, assessed the adversity of actions similar to those that the EWA agencies would take (Table 11-24).

Table 11-24
Information from Other Studies Related to Socioeconomic Effects for Land Idling

Example/Source	*Action*	*Results*	*Substantial/Not Substantial*
Draft report by USBR – "Economic Impacts of Fallowing Irrigated Land in the Imperial Irrigation District" (2001)	5% Reduction in county water supply	County employment reduced by 0.1%; county economic activity (output) reduced by 0.2%	Effects considered not substantial
Yolo County – "California Water Transfers, Gainers and Losers in Two Northern Counties" (1992)	16% reduction in county water supply (154,323 acre-feet) from Drought Water Bank (DWB)	County employment reduced by 0.6%; agricultural related income down 5%	Farmers felt that effects were not substantial (they were being compensated); community leaders felt that it was substantial (initiated lawsuit).
"California's 1991 DWB, Economic Impacts in Selling Regions" – Rand Report (1993)	DWB water transfers made available a total of 820,805 acre-feet of water from 13 California counties	Reduction in agricultural related income was "not large" compared to variation experienced in 1980's; no relationship found between DWB effects and overall county economies.	Effects considered not substantial
"Agriculture-to-Instream and Urban Water Transfers in the Central Valley of California: An Economic Reality Check" – CH2M HILL (1998)	Transfer of 1 MAF from Central Valley irrigation use to instream and urban uses	Net personal income reduced by $170 for every AF water transferred and 8 jobs lost for every 1 thousand acre-feet (TAF) water transferred. Total effects are 2% to 3% of regional total.	Not substantial regionally, but effects could be more concentrated in a few areas of origin.
"Water Marketing in California. Resolving Third-Party Impact Issues" – David Mitchell (1992)	Water transfers (in general)	"Impacts are well within the range of ordinary economic consequences that arise from changing circumstances in a market economy."	Effects considered not substantial

11.2.4 Environmental Consequences/Environmental Impacts of the No Action/No Project Alternative

The No Action/No Project Alternative represents future conditions during Stage 1 of CALFED if the EWA were not implemented. In general, agricultural economies would not likely change in the future. Farmers would continue to idle some land temporarily and would continue to rotate other previously idled land back into production as common land management practices and in response to market issues,

and as a result of water supply shortages. These farming practices cause normal variations in total value of output, value added, wages and salaries, and employment. The conditions under the No Action/No Project Alternative generally reflect the conditions described in the Affected Environment/Existing Conditions section. This analysis further refers to the Affected Environment/Existing Conditions as the Baseline Condition.

Several CALFED and other government-sponsored programs would retire irrigated land for restoration and habitat purposes, reducing agricultural land. Section 11.2.8, Cumulative Effects, discusses these potential effects.

11.2.5 Environmental Consequences/Environmental Impacts of the Flexible Purchase Alternative

The Flexible Purchase Alternative allows transfers up to 600,000 acre-feet each year and does not specify transfer limits from the Upstream from the Delta Region or the Export Service Area. Transfers from the Upstream from the Delta Region would range from 50,000 to 600,000 acre-feet each year, depending on hydrologic year type and excess conveyance capacity through the Delta each year. Even though all potential transfers would not occur in some years, this section assumes the 600,000 acre-feet level in order to discuss the maximum economic effects for the transfer scenario. Therefore, the crop idling acreages indicated in the analysis represent maximum crop idling actions and would not likely occur in any one year.

11.2.5.1 Upstream from the Delta

The county-level analysis includes Butte, Glenn, Colusa, Placer, Sutter, and Yolo Counties. These counties all have large amounts of rice acreage and various water agencies that have expressed some willingness to sell water to the EWA (refer to Chapter 2). Shasta and Solano Counties produce no or little rice; therefore, the analysis excludes them (CASS 2001). Tehama and Sacramento Counties do not produce enough rice acreage to provide a significant contribution to the water supply needs of the EWA and were also omitted. Furthermore, the analysis excludes Sacramento County because of its expansive baseline economy, which, if included, would dilute any economic effects. Although Yuba County had over 36,000 acres of rice in 2000, Yuba County Water Agency has stated that it would not participate in crop idling water transfers with the EWA. Any rice acreage in Yuba County outside of the Yuba County Water Agency boundaries would not be a significant source of water for the EWA. Therefore, the county analysis does not include idling in Yuba County. Yuba County was included in the regional analysis with the other six counties because the rice mills in Yuba County serve multiple counties within the region (Davis 2002).

11.2.5.1.1 Regional Analysis

The regional analysis evaluates changes in economic activity that result from idling rice acreage. The region is defined as Butte, Colusa, Glenn, Placer, Sutter, Yolo and Yuba Counties. The IMPLAN data set (1997) provides baseline value of output, value

added, wages and salaries, and employment data for this analysis. Value of output is value of production. Value added consists of wages and salaries, proprietor's and property incomes, dividends and interest, and indirect business taxes. Employment is the number of jobs at industries in the region and is measured in full-time job equivalents.

The Upstream from the Delta Region analysis considers only rice for idling. Of all common crops, rice provides the largest amount of water per acre idled, approximately 3.3 AF of ETAW per acre.[11] In past and recent water transfer programs and agreements, rice farmers have enrolled their crop for idling. Therefore, rice farmers would represent a potential seller to the EWA.

Table 11-25 summarizes the baseline conditions for the region. These data are from the 1997 IMPLAN data set. IMPLAN accounting conventions differ slightly from some other common economic data measurement standards.[12] Placer and Yolo Counties, which include some urban areas near Sacramento, contribute most to the baseline economy of the region.

Table 11-25

Source: 1997 IMPLAN Data Set

(1) Counties included are Butte, Colusa, Glenn, Placer, Sutter, Yolo, and Yuba.

Economic effects would occur only to the extent that water is obtained by land idling (see Section 11.2.7). Effects would occur only in years when the crop idling actions take place and effects would be less when less land is idled. Therefore, the average effect of a land idling scenario over a number of years would be less than the effects described below.

EWA acquisition of water via crop idling of rice acres in the Upstream from the Delta Region would decrease net revenues to some tenant farmers whose landowners choose to participate in the EWA.

Tenant farmers, those who rent land from property owners, could be adversely affected by the crop idling. The landowner would receive revenues from the sale of the water instead of rent from the tenant, but the tenant farmer would not receive the

---

11 3.3 AF/acre is the estimated evapotranspiration of applied water (ETAW) per acre for rice used in the economic analysis. Evapotranspiration is total water loss due to free-water evaporation, plant transpiration, and soil-moisture evaporation. ETAW is the portion of the total evapotranspiration that is provided by irrigation as opposed to precipitation. DWR calculates normal year ETAW values using information and methodologies from established sources. ETAW is the commonly accepted measure of surface water savings due to crop shifting or idling (Water Transfers Office 2002).

12 Bureau of Economic Analysis (BEA) Commodity Classifications, which form the basis of the IMPLAN technical matrix, can vary from Standard Industrial Classifications.

net revenue from rice production. If there is no other land available for rent, or if land rents are increased, the tenant farmer would be worse off.

For several reasons, this type of effect may be the exception rather than the rule. Full owners operated about 65 percent of farms in the Upstream from the Delta Region in 1997 (USDA 1999) and part owners operated most of the remaining farms. Tenant farmers may be able to rent other parcels of land or engage in alternative economic activity. A tenant farmer could also be an owner of some land. In other cases, tenants could have formal or informal agreements with landowners that would result in sharing of the water transfer revenue.

EWA acquisition of water via crop idling of rice acres in the Upstream from the Delta Region would increase net revenues to individual farmers/landowners participating in the EWA.

Land enrollment in the EWA program is voluntary and farmers would be paid to participate. If farmers participate, the expected net return from the water transfer must exceed the expected net return from growing the crop to be idled, so farmers expect to be better off. If they do not participate, they are no worse off, at least with respect to their own farming decision.

The economics of participation for a representative farm can be shown using results from DEIM. DEIM models a representative farm using 1995 to 1999 agricultural prices and recent farm production costs (DWR 2002). Table 11-26 compares the net revenues gained by the water transfer in DEIM to the revenue lost from discontinued rice production. The model assumes the farmer receives $50 for each acre-foot, after water costs, for water made available by idling rice land. DEIM found that this price should be sufficient to compensate rice landowners for their net revenue losses under 1995 to 1999 conditions.

Rice provides 3.3 acre-feet ETAW of water per acre when idled; therefore, the farmer would receive $165 per acre of rice idled under the DEIM price. Various land idling expenses would offset some of this income. The farmer would forego all rice production, and would give up the value of the crop sales less variable costs avoided (DWR 2002). Under current farm program rules, farmers obtain a government payment per acre of rice land enrolled in the commodity program in any case. Therefore, temporary participation in water transfers will not affect the government payment.

Table 11-26
Net Revenue From Water Transfer, Lost Revenue, Variable Costs Avoided and Lost Return Over Variable Costs, 1997 dollars
(Dollars per Acre)

	(1)	*(2)*	*(3)*	*(4)*	*(5)*	*(6)*
County/Crop	*Water Transfer Price, $/AF*	*Net Revenue from Water Transfer*	*Revenue from Crop Production (lost)*	*Variable Costs Avoided by the Transfer*	*Net Revenue from Crop Production (lost) (3) - (4)*	*Net Revenue gained from Water Transfer (2) – (5)*
Butte/Rice	50	128	641	552	89	39
Colusa/Rice	50	130	616	551	64	66
Glenn/Rice	50	128	656	656	98	30
Placer/Rice	50	131	530	542	-12	143
Sutter/Rice	50	130	614	547	67	63
Yolo/Rice	50	129	627	554	72	57

Source: DWR 2002.

(1) The model assumes the farmer/land owner receives $50 for each acre-foot made available by idling rice land. Water transfer prices are net to farmer after water costs are paid.
(2) Net Revenue from Water Transfer is the water transfer revenue less costs required when land is idled. Land idling costs differ slightly among counties (DWR 2002).
(3) Revenue from Crop Production is value that the crop would have produced, not including direct government payments.
(4) Variable Costs Avoided by the Transfer are farming costs that would be avoided if the land were idled.
(5) = (3) – (4). Net Revenue from Crop Production equals Revenue from Crop Production minus Variable costs of crop production, or, the revenue that the farmer would have received by producing crops on the land, for example, it is negative if variable costs avoided by the transfer exceed lost revenue from crop production.
(6) = (2) – (5). Net Revenue gained from Water Transfer equals Net transfer revenue minus Lost Net Revenue from Crop Production.

As Table 11-26 shows, the net revenue received per acre from a water transfer (2) is larger than the net revenue received from crop production (5). The water transfer price could be even less than $50 per acre-foot, and the transfer would still provide a positive net revenue to the farmer.

It should be noted that $50 per acre foot is a representative price used for modeling and would likely vary according to hydrologic conditions and prices in agricultural markets. Table 11-32 provides sensitivity analysis of economic impacts at higher prices.

EWA acquisition of water via crop idling of rice acres in the Upstream from the Delta Region would decrease the total value of output, value added, wages and salaries, and employment in the region.

Farmers selling water to the EWA from idled land would be compensated for expected losses in net income from not growing rice; however, indirect and induced effects create losses for persons who trade with farmers.

Table 11-27 summarizes the total annual effects per acre of idling rice in the Upstream from the Delta Region estimated from DEIM. In the rice idling action, if one acre of rice were idled, there would be a $2,488 decrease in total value of output, a $960 decrease in value added, a $499 decrease in wages and salaries, and 25 jobs lost.

Again, these effects would take place only in years when the crop idling actually occurs. Land idling actions would not occur every year. As the actions occur less frequently, the average annual effect becomes less. For example, if a scenario results in a 1 percent loss in output, but the idling would actually occur only once every 3 years, then the average annual loss in output would be only one-third of 1 percent.

Table 11-27
Value of Output, Value Added, Wages and Salaries, and Employment - Total Effect of Idling Rice per Acre In Upstream from the Delta Region, 1997 dollars

Upstream from the Delta Region Action	*Value of Output $/acre*	*Value Added $/acre*	*Wages and Salaries $/acre*	*Employment # of jobs/1000 acres*
Rice Idling [1]	-$2,488	-$960	-$499	-25

Source: DEIM 2002

[1] Results are specific to the distribution of acreages across counties described in the county analyses. The per-acre regional effects would change when the county acreage distributions change.

Table 11-28 shows the regional effects of acquiring water by idling rice. The effects are expressed as a percentage change to the baseline conditions in Table 11-25. If 89,600 rice acres were idled, it would cause a less than one percent effect to the region's economy as measured by four key parameters. The effect on the region's rice economy or even the region's agricultural economy would be larger on a percentage basis; however, there are no standard measures for the size of the rice or agricultural economies in a region. Section 11.2.5.1.3 discusses local effects.

Table 11-28
Description of Potential EWA Rice Idling Action Upstream from the Delta Region

Total Acres	*Action*	*Maximum Idled Acres*	*Portion of Total Rice Acres*	*Change in Output Relative to Baseline[1]*	*Change in Value Added Relative to Baseline[1]*	*Change in Wages and Salaries Relative to Baseline[1]*	*Change in Employment Relative to Baseline[1]*
448,158	Rice Idling	89,600	20.0%	-0.69%	-0.45%	-0.43%	-0.54%

Source: DEIM 2002

[1] Percentages represent reductions to baseline values. The percentages translate into the following dollar losses to the four parameters: total value of output would decrease by $222.9 million, value added would decrease by $86.0 million, wages and salaries would decrease by $44.8 million and 2218 jobs would be lost.

11.2.5.1.2 County Analysis

The county analysis describes changes in county value of output, value-added, wages and salaries, and employment to individual counties that result from idling rice acreage. Effects to individual landowners and tenant farmers were described qualitatively in Section 11.2.5.1.1. Table 11-29 describes the baseline conditions in the counties in which rice idling might occur.

Table 11-29
Upstream from the Delta Region County Baseline Conditions, Million 1997 $ and Jobs

County	Value of Output Baseline	Value Added Baseline	Wages and Salaries Baseline	Employment, Jobs Baseline
Butte	6,319	3,803	2,063	96,329
Placer	11,081	6,506	3,258	125,480
Colusa	1,085	456	212	10,781
Glenn	1,071	504	254	12,308
Sutter	2,707	1,606	780	38,201
Yolo	8,365	5,064	3,081	98,433

Source: 1997 IMPLAN Data set

Economic effects would occur only to the extent that water is obtained by land idling. (See Section 11.2.7 for explanation of crop idling amounts during wet and dry years.) Effects would occur only in years when the crop idling actions take place, and effects would be less when less land is idled. Therefore, the average effect of a crop idling scenario over a number of years would be less than the effects described below.

EWA acquisition of water via crop idling of rice acres in Butte, Colusa, Glenn, Placer, Sutter, and Yolo Counties would decrease total value of output, value added, wages and salaries, and employment in each county.

Table 11-30 summarizes the total effects per acre of idling rice land, as estimated by DEIM. There is variation among counties because some counties do not have operating rice mills and some counties have more economic leakage[13] than other counties. Most of the job losses involve agricultural services, on-farm employment and rice milling, if mills operate in the county.

Table 11-30
Total County Effect of Idling Rice, 1997 dollars

County	Value of Output $/acre	Value Added $/acre	Wages and Salaries $/acre	Employment # of jobs/1000 acres
Butte	-$2,777	-$1,093	-$543	-30
Colusa	-$1,982	-$628	-$357	-18
Glenn	-$1,332	-$584	-$323	-23
Placer	-$1,441	-$653	-$335	-19
Sutter	-$1,563	-$647	-$361	-22
Yolo	-$2,455	-$931	-$530	-23

Source: DEIM 2002

The section below describes the potential effects of EWA water acquisition through rice idling. As Section 11.2.3.1 explained, no more than 20 percent of baseline rice acreage would be idled under EWA water acquisitions.

This scenario includes approximately 89,600 acres of rice land idling. The following economic effects are calculated from DWR's DEIM model using the per-acre estimates

[13] Leakages are out-shipments of money from a local economic region, mostly payments made to non-local residents for goods, materials and production factors that are used in the region, but are brought in from outside the region.

described in Table 11-30. Table 11-31 presents these dollar amounts as a percentage loss to the baseline values.

- Idling 19,000 rice acres in Butte County would result in a $52.8 million total decrease in value of output, a $20.8 million decrease in value added, a $10.3 million decrease in wages and salaries, and a loss of 570 jobs.
- Idling 26,460 rice acres in Colusa County would result in a $52.4 million total decrease in value of output, a $16.6 million decrease in value added, a $9.4 million decrease in wages and salaries, and a loss of 476 jobs.
- Idling 16,750 rice acres in Glenn County would result in a $22.3 million total decrease in value of output, a $9.8 million decrease in value added, a $5.4 million decrease in wages and salaries, and a loss of 385 jobs.
- Idling 3,280 rice acres in Placer County would result in a $4.7 million total decrease value of output, a $2.1 million decrease in value added, a $1.1 million decrease in wages and salaries and a loss of 62 jobs.
- Idling 19,340 rice acres in Sutter County would result in a total of $30.2 million decrease in value of output, a decrease of $12.5 million in value added, a decrease of $7.0 million in wages and salaries, and a loss of 425 jobs.
- Idling 4,770 rice acres in Yolo County would result in an $11.7 million total decrease in value of output, a $4.4 million decrease in value added, a $2.5 million decrease in wages and salaries and a loss of 110 jobs.

Table 11-31
Economic Effects of Alternative Rice Idling Action in Counties in the Upstream from the Delta Region

	Maximum Rice Idling Action			***Percent Economic Effect[2]***			
County	***Total Rice Acres[1]***	***Maximum Idled Acres***	***% of Total Acres Idled***	***Value of Output***	***Value Added***	***Wages and Salaries***	***Employment***
Butte	95,120	19,000	20.0%	-0.84%	-0.55%	-0.50%	-0.59%
Colusa	132,338	26,460	20.0%	-4.83%	-3.64%	-4.46%	-4.42%
Glenn	83,777	16,750	20.0%	-2.08%	-1.94%	-2.13%	-3.13%
Placer	16,379	3,280	20.0%	-0.04%	-0.03%	-0.03%	-0.05%

Yolo	23,822	4,770	20.0%	-0.14%	-0.09%	-0.08%	-0.11%
Total	448,158	89,600	20.0%				

Source: DEIM 2002

(1) The figures representing total rice acres within the counties are based on a five-year average to take into account any recent land trends in rice production. The data is taken from the County Agricultural Commissioners Reports from 1995 to 1999.
(2) These percentages represent reductions to baseline values.

The economic effects of water transfers from rice land would vary depending on many conditions. Table 11-32 shows the effects per acre of idling rice in Colusa and Glenn Counties at higher water prices of $75 and $100. The county-level negative effects of idling rice become smaller as the price of water increases. At higher prices,

the water transfer revenue would provide more offset to the negative effects of idling. The overall negative effect of crop idling to output, value-added, wages and salaries, and employment, however, does not appear to be very sensitive to the price of water.

Farmers would likely spend a percentage of the increased net revenue received from a water transfer in their local economy. Farmers may decide to invest in new equipment for the farm, increasing revenue for the agricultural sector, or they may choose to spend money in the trade, services, finance, or other sectors of the economy. This would result in higher sales for these sectors. The analysis of the effects of water price changes show that the spending boost provided by increased net revenues from water transfers would not offset the negative effects from land idling. As Table 11-32 indicates, in Colusa County, a $50 increase in farmer's net revenue would only lessen the reduction to total output by $153.

Table 11-32
Total County Effect of Idling Rice in Colusa and Glenn Counties Under Different Water Prices, 1997

County	Price of Water to Farmer ($/AF)	Value of Output $/acre	Value Added $/acre	Wages and Salaries $/acre	Employment # of jobs/1000 acres
Colusa	$50	-$1,982	-$628	-$357	-18.5
	$75	-$1,905	-$602	-$345	-17.8
	$100	-$1,829	-$575	-$333	-17.1
Glenn	$50	-$1,332	-$584	-$323	-22.8
	$75	-$1,252	-$559	-$312	-22.1
	$100	-$1,171	-$535	-$302	-21.4

Water transfer prices are net to farmer after water costs are paid.

11.2.5.1.3 Local Analysis

The following is a qualitative discussion of local third-party economic effects. For this analysis, local effects mean effects on towns, communities and local industries. Local economic data do not exist for all communities, and the locations of EWA rice land idling within counties cannot be predicted with certainty. Therefore, this analysis does not attempt to predict economic effects in specific communities, and the analysis of local effects is handled descriptively and qualitatively. In the future, experience will allow the EWA agencies to anticipate where most adverse local effects might be.

The effects of the rice idling action described above are changes in value of output, value added, wages and salaries, and employment at the regional or county levels. Large urban centers in some counties create large baseline economic values. Rural communities have a much smaller economic base, and any change to economic levels would be more adverse relative to the larger regional and county economies. Even if a community were not adversely affected, some persons within the community may be affected.

The majority of rice fields in the Upstream from the Delta Region are along the Interstate-5 corridor in Glenn and Colusa Counties, between the I-5 and Highway-99 corridors in Butte and Sutter Counties, and in western Placer County. Most of the

communities in these areas are small and dependent on agriculture. Some of the agriculturally based communities include Artois and Willows in Glenn County; Maxwell, Arbuckle, and Grimes in Colusa County; Richvale and Biggs in Butte County; and numerous others. These towns often house companies associated with rice production, such as seed and fertilizer suppliers, aerial application services, rice mills, and rice driers and storage warehouses that rely on rice production for revenue. These companies also provide employment to many local residents.

Interviews with several managers and operators of rice mills, aerial application services, and rice storage warehouses indicated that the companies are volume driven. If rice production is reduced, adverse effects occur. Aerial applications and other custom operations would not occur on idled lands, resulting in a loss of revenue. Fertilizer, herbicide, and seed companies would also lose sales if farmers did not plant rice. Furthermore, rice idling would reduce the demand for haulers and harvest equipment operators. Equipment rentals and fuel sales would decrease as well (Hoff 2002).

Idling rice land would cause a decrease in revenue and employment for many companies involved in rice production. These effects would generally be adverse to both business owners and employees. Decreased revenue and employment at rice mills would result in less local spending.

The adverse effects are likely to be larger if the idled land is near a local community far from any large urban center, because a larger share of expenses is likely to be paid to local businesses. Residents of rural communities far from urban centers typically spend larger portions of their incomes within the community than residents of rural communities that are close to large urban centers.

Leakages are out-shipments of money; for example, payments made to non-residents for imported goods, materials, and production factors. The share of income or revenue that becomes leakage is generally larger when there are more shopping opportunities outside the local community. Therefore, the adverse effects of land idling would be larger for land that is close to communities located far from urban centers.

Farmland owners would realize a net gain in net revenue by selling water to the EWA, as described above. Presumably, farmers or landowners would spend some of their increased net revenues in the local economy. This effect could offset some of the decrease in local spending by the third parties described above. The analysis of the effects of water price changes in Table 11-32 suggests that the spending boost provided by increased net revenues from water transfers will not offset the negative effects from land idling.

11.2.5.2 Export Service Area

The Export Service Area analysis includes Fresno, Tulare, Kings and Kern Counties. In this analysis, the region does not include southern California. Stanislaus and San Joaquin Counties produce very little, if any, cotton. Although Madera and Merced Counties have cotton crops, water agencies in these counties are not selling water or are only selling groundwater supplies to the EWA; therefore, these counties were also excluded from the analysis. Fresno, Kern, Kings, and Tulare Counties all have large amounts of cotton acreage and water agencies that have expressed some interest in selling water to the EWA. Therefore, EWA actions may affect these counties.

11.2.5.2.1 Regional Analysis

The regional analysis evaluates changes in value of output, value-added, wages and salaries, and employment that would result from idling cotton. This analysis considers only cotton for idling in this region because cotton farmers in the Export Service Area have shown willingness to sell water to the EWA. (Refer to Chapter 2 for further discussion.) Cotton provides approximately 2.3 acre-feet ETAW of water per acre idled.[14]

The models for Fresno, Tulare, Kings and Kern Counties assume that only upland cotton would be idled in these counties. EWA agencies are not planning to purchase water though idling pima and other cotton varieties. Therefore, the regional and county analysis does not include potential idling of pima cotton and other varieties.

Table 11-33 summarizes the baseline conditions of the region. These data are from the 1999 IMPLAN data set for Fresno, Kern, Kings and Tulare Counties.

Table 11-33

Export Service Area include Fresno, Kern, Kings, and Tulare Counties.
Source: 1999 IMPLAN data set. IMPLAN accounting conventions differ slightly from some other common economic data measurement standards.

Economic effects would occur only to the extent that water is obtained by crop idling. (See Section 11.2.7 Comparative Analysis.) Effects would occur only in years when EWA agencies acquire water through crop idling actions, and effects would be less when less land is idled. Therefore, the average effect of a crop idling scenario over a number of years would be less than the effects described below.

[14] 2.3 AF/acre is the estimated ETAW for cotton used in the economic analysis. Refer to footnote 2 in section 11.2.3.1.1 for further definitions.

EWA acquisition of water via crop idling of cotton acres in the Export Service Area would decrease net revenues to some tenant farmers whose landowners choose to participate in the EWA.

Tenant farmers, those who rent land from property owners, could be adversely affected by the EWA crop idling actions. The landowner would receive revenues from the sale of the water instead of rent from the tenant, but the tenant farmer would not receive the net revenue from cotton production. If there is no other land available for rent, or if land prices are increased, the tenant farmer would be worse off.

For several reasons, this type of effect may be the exception rather than the rule. Full owners operated about 73 percent of farms in the Region in 1997 (USDA 1999) and part owners operated about 16 percent. Tenant farmers operated only about 11 percent of farms in the region. Tenant farmers may be able to rent other parcels of land or engage in alternative economic activity. A tenant farmer could also be an owner of some land. In other cases, tenants could have formal or informal agreements with landowners that would result in sharing of the water transfer revenue.

EWA acquisition of water via crop idling of cotton acres in the Export Service Area would increase net revenues to farmland owners participating in the EWA.

Land enrollment in the EWA program is voluntary and farmland owners would be paid to participate. If farmland owners participate, the expected net return from the water transfer must exceed the expected net return from growing the crop to be idled, so farmers expect to be better off. If they do not participate, they are no worse off, at least with respect to their own farming decision.

DEIM results can show the economics of participation for a representative farm. DEIM models a representative farm using 1995 to 1999 agricultural prices and recent farm production costs (DWR 2002).

Table 11-34 compares the net revenues gained by the water transfer to the net revenue lost from discontinued cotton production. The model assumes that the farmer receives $150 per acre-foot of water idled in Kern and Tulare Counties, $120 in Kings County and $200 per acre-foot in Fresno County. DEIM suggests that these prices should be sufficient to induce landowners to participate. The analysis assumes that cotton net returns in Fresno County may be higher than other counties evaluated; however, individual lands vary in capability, and these assumptions may not apply to lands entering the EWA Program. The EWA agencies may not be willing to pay different amounts in each county.

Cotton provides about 2.3 acre-feet of water per acre when idled. Under prices assumed by the model, the farmer would receive $345 per acre of cotton idled in Kern and Tulare, $276 in Kings County, and $460 in Fresno. Various land-idling expenses, such as certain machinery costs, petroleum, material and custom costs, would offset some of this income (DWR 2002). The farmer would forego all cotton production, and

would give up the value of the crop sales less variable costs (DWR 2002). Table 11-34 shows that the transfer revenues are sufficient to compensate the farmer for losses in net returns from cotton production.

Table 11-34
Net Revenue From Water Transfer, Lost Revenue, Variable Costs Avoided and Lost Return Over Variable Costs, Dollars per Acre, Export Service Area, 1997 dollars

	(1)	*(2)*	*(3)*	*(4)*	*(5)*	*(6)*
County/Crop[7]	*Water Transfer Price, $/AF*	*Net Revenue from Water Transfer*	*Revenue from Crop Production (lost)*	*Variable Costs Avoided by the Transfer*	*Net Revenue from Crop Production (lost) (3) – (4)*	*Net Revenue gained from Water Transfer (2) – (5)*
Fresno/Cotton	200	402	1035	634	402	0
Kern/Cotton	150	287	900	634	266	21
Kings/Cotton	120	218	797	634	163	55
Tulare/Cotton	150	287	857	634	223	64

(1) Water transfer prices are net to farmer after water costs are paid.
(2) Net Revenue from Water Transfer is the water transfer revenue less costs required when land is idled. Land idling costs differ slightly among counties (DWR 2002).
(3) Revenue from Crop Production is value that the crop would have produced, not including market transition payment (government payment).
(4) Variable Costs Avoided by the Transfer are farming costs that would be avoided if the land were idled.
(5) = (3) – (4). Net Revenue from Crop Production equals Revenue from Crop Production minus Variable costs of crop production, the revenue that the farmer would have received by producing crops on the land (It is negative if variable costs avoided by the transfer exceed lost revenue from crop production).
(6) = (2) – (5). Net Revenue gained from Water Transfer equals Net Transfer Revenue minus Lost Net Revenue from Crop Production.
(7) Revenues and costs apply to upland Acala cotton.

EWA acquisition of water via crop idling of cotton acres in the Export Service Area would decrease the total value of output, value added, wages and salaries, and employment in the region.

Farmers selling water to the EWA from idled land would be compensated for their expected losses in income; however, indirect and induced effects would still occur. Table 11-35 summarizes the regional economic effects of idling an acre of upland cotton estimated from DEIM.

Table 11-35
Value of Output, Value Added, Wages and Salaries and Employment - Total Regional Effect of Idling Cotton, 1997

Export Service Area Action	*Value of Output $/acre*	*Value Added $/acre*	*Wages and Salaries $/acre*	*Employment # of Jobs/1000 Acres*
Cotton Idling Action	-$1,613	-$454	-$284	-15

Results are specific to the distribution of acreages across counties as described in the county analysis (Section 11.2.5.2.2). The per-acre regional effects would change when the county acreage distributions change due to the different economies of the counties.

Source: DEIM 2002

Table 11-36 shows the regional effects of acquiring water through cotton idling. In this scenario, 20 percent of total regional cotton acres would be idled. The effects are expressed as a percentage reduction to baseline conditions in Table 11-31. The total effects of idling 182,800 cotton acres in the region would be a $294.9 million total decrease in value of output, an $82.9 million decrease in value added, a $51.9 million

decrease in wages and salaries and 2,806 jobs lost. These EWA effects represent less than one-half of 1 percent of the regional economy. Section 11.2.5.2.3 addresses effects on local economies.

Table 11-36
Description of EWA Cotton Idling Actions in Export Service Area

Total Acres	Action	Maximum Idled Acres	Portion of Total Cotton Acres	Change in Output Relative to Baseline[1]	Change in Value Added Relative to Baseline[1]	Change in Wages and Salaries Relative to Baseline[1]	Change in Employment Relative to Baseline[1]
914,719[2]	Cotton Idling	182,800	20.0%	-0.42%	-0.20%	-0.24%	-0.30%

Source: DEIM 2002

(1) Percentages represent reductions to baseline values.
(2) Total cotton acreage include upland, pima and other cotton varieties planted in Fresno, Kern, Kings and Tulare Counties.

Farmers would likely spend a percentage of the increased net revenue received from the water transfer in their local economy. Farmers may decide to invest in new equipment for the farm, increasing revenue for the agricultural sector, or they may choose to spend money in the trade, services, finance, or other sectors of the economy. This would result in higher sales for these sectors. Analysis of the effects of water price changes suggests that the spending boost provided by increased net revenues from water transfers would not offset the negative effects from land idling.

11.2.5.2.2 County Analysis

The county analysis evaluates changes in value of output, value-added, wages and salaries, and employment to individual county economies that results from idling cotton. Effects to individual landowners and tenant farmers were described qualitatively in Section 11.2.5.2.1. Table 11-37 describes the baseline conditions in the counties in which cotton idling might occur.

Table 11-37
Export Service Area County Baseline Conditions, 1997dollars

County	Value of Output, Million $ Baseline	Value Added, Million $ Baseline	Wages and salaries, Million $ Baseline	Employment, jobs Baseline
Fresno	31,803	18,139	9,883	416,932
Kern	23,988	14,436	7,669	305,432
Kings	3,842	2,253	1,298	47,756
Tulare	12,132	6,652	3,554	171,036

Source: 1999 IMPLAN Data set

Economic effects would occur only to the extent that water is obtained by land idling (see Section 11.2.7). Effects would occur only in years when the crop idling actions take place, and effects would be less when less land is idled. Therefore, the average effect of a land idling scenario over a number of years would be less than the effects described below.

EWA acquisition of water via crop idling of cotton acres in Fresno, Kern, Kings, and Tulare Counties would decrease total value of output, value added, wages and salaries, and employment in each county.

Table 11-38 summarizes the economic effects per acre of idling cotton on value of output, value added, wages and salaries, and employment, as determined by DEIM.

Table 11-38
Total County Effect of Idling Cotton, 1997 dollars

County	Value of Output $/acre	Value Added $/acre	Wages and Salaries $/acre	Employment # of Jobs/1000 Acres
Fresno	-$1775	-$477	-$294	-16
Kern	-$1614	-$467	-$291	-15
Kings	-$1398	-$403	-$258	-15
Tulare	-$1470	-$411	-$262	-15

Source: DEIM 2002

This section describes the potential effects of EWA water acquisitions through cotton idling.

This scenario includes 182,800 acres of cotton crop idling. DWR's DEIM calculates these results using per acre estimates described in Table 11-38. Table 11-39 presents these dollar amount as a percentage loss to the baseline values.

- Idling 70,500 cotton acres in Fresno County would result in a $125.1 million total decrease in value of output, a $33.6 million decrease in value added, a $20.7 million decrease in wages and salaries, and a loss of 1,127 jobs.

- Idling 49,300 cotton acres in Kern County would result in a $79.6 million total decrease in value of output, a $23.0 million decrease in value added, a $14.4 million decrease in wages and salaries, and a loss of 752 jobs.

- Idling 44,500 cotton acres in Kings County would result in a $62.2 million decrease in total value of output, a $17.9 million decrease in value added, an $11.2 million decrease in wages and salaries, and a loss of 668 jobs.

- Idling 18,500 cotton acres in Tulare County would result in a $27.2 million total decrease in value of output, a $7.6 million decrease in value added, a $4.8 million decrease in wages and salaries, and a loss of 276 jobs.

This cotton idling scenario would reduce value of output, value added, wages and salaries, and employment in Fresno, Kern, and Tulare Counties by less than one half of one percent. In Kings County, the effects would range from 0.8 percent to 1.6 percent of the baseline values. Section 11.2.5.2.3 addresses effects on local economies.

Table 11-39
Economic Effects of Alternative Cotton Idling Actions in Export Service Area Counties

Cotton Idling Action				Percent Economic Effect[2]			
County	Total Cotton Acres[1]	Maximum Idled Acres	% of Total Acres Idled	Value of Output	Value Added	Wages and Salaries	Employment
Fresno	352,880	70,500	20.0%	-0.41%	-0.19%	-0.22%	-0.28%
Kern	246,616	49,300	20.0%	-0.33%	-0.16%	-0.19%	-0.25%
Kings	222,543	44,500	20.0%	-1.62%	-0.80%	-0.88%	-1.40%
Tulare	92,680	18,500	20.0%	-0.22%	-0.11%	-0.14%	-0.16%
Total	914,719	182,800	20.0%				

Source: DEIM 2002

(1) The figures representing total cotton acres within the counties are based on a five-year average to take into account any recent land trends in cotton production. The data is taken from the County Agricultural Commissioners Reports from 1995 to 1999.
(2) Percentages represent reductions to baseline values.

The results in Table 11-39 are predicated on the water prices shown in Table 11-34. Actual water prices will vary from year to year as hydrologic conditions and conditions in agricultural markets change; however, the results of the regional analysis are not very sensitive to water price. For example, if the price of water in Kings County is increased 50 percent to $180 per acre-foot, the adverse effect on output is reduced from $1,398 per acre to $1,261 per acre, or about 10 percent. The adverse effect is not substantially reduced. This sensitivity analysis also supports the premise that, although increases in water transfer revenue increase farmer spending and offsets some of the economic loss from idling land, the amount of offset would not eliminate the negative effect from idling land.

11.2.5.2.3 Local Analysis

The following is a qualitative discussion of local third party economic effects. Third-party economic effects in the Export Service Area would be similar to those in the Upstream from the Delta Region. The majority of cotton fields in the region are in western Kern County, in the Tulare Lake Basin in Kings and Tulare Counties and in western Fresno County. Crop idling would affect the small, rural communities in this area, where agriculture is the major source of income and employment.

Most of the agricultural companies in the area depend on volume for revenue. A reduced volume of cotton production would cause cotton gins to lose revenues and would result in a decrease in employment opportunities. Although the loss of gross revenue and jobs may be small relative to the total economic activity in a region, that loss would be concentrated in just one industry – cotton. The infrastructure that supports the region's cotton industry could be reduced in the long run, due to the ongoing land-idling operations of the EWA program, land retirement, and other factors that may idle cotton land.

Third-party economic effects would occur locally. Businesses directly involved with cotton production and processing, such as seed and fertilizer supply stores and cotton gins, would lose both revenue and employment. Local spending would decrease. These effects would adversely affect the business owners, whose revenues could decrease, and the employees, who could lose their jobs.

Farmers and landowners would increase their net revenue by selling water to the EWA, as described above. Presumably, farmland owners would spend some of their increased net revenues in the local economy. This effect could potentially partially offset the decrease in local spending by the third parties described above. Analysis of the effects of water price changes suggests that the spending boost provided by increased net revenues from water transfers would not offset the negative effects from land idling.

11.2.5.3 Effects on Tax Revenue

EWA acquisition of water through crop idling could change county property tax revenues.

Local governments are dependent on property tax revenues for financing of local services and education. Water acquisitions via crop idling could affect property taxes if they affect property values. For landowners of irrigated land, water transfers represent a potential source of profits. Theoretically, if a farmer voluntarily transfers water, then expected profits from the sale of water must exceed the profits expected from farming the land. The opportunity provided by voluntary transfers increases long-run average economic returns to irrigated land. Therefore, property values should increase. Subsequently, property tax revenues to the county would also increase.

One economic issue associated with land idling is the potential for Open Space Subvention Act revenue losses to be caused by a reclassification of "Prime" land to non-prime land, as defined under the Williamson Act. County tax revenue could potentially decrease if land idling results in the State reclassifying lands enrolled in the Williamson Act to lower levels. Under the Open Space Subvention Act, county governments receive subvention payments to replace lost property tax revenues from lands enrolled in the Williamson Act. Lands classified as prime land under the Williamson Act qualify for a $5 per acre subvention payment, and lands other than prime farmland qualify for a $1 per acre subvention payment.

In order to determine whether crop idling by the EWA would alter the classification of prime farmland, it is important to consider the land use and production value during the prior years of the particular parcel to be idled (Bryant 2003). Cropland could be downgraded from the prime category if the land was idled for 3 or more of the last 5 years. The EWA Project Agencies would consider the cropping patterns' history during the previous 5 years of the parcel of land before purchase. Chapter 13 identifies mitigation measures that propose limits for EWA crop-idling purchases to avoid changing the classification of lands under the Williamson Act. Therefore, with this mitigation measure in effect, the decrease in subvention payments to county governments would not likely occur.

EWA acquisition of water though crop idling could cause a decrease in sales tax revenue to the county.

Retail sales at agricultural supply stores and certain other retail outlets would decrease because of land idling. Decreased sales would reduce sales tax revenue returned to the county. Sales taxes are roughly 7 percent of retail sales, and one percent is returned directly to the county. The effect of a 1-acre reduction of rice in the counties in the Upstream from the Delta Region on sales tax revenue returned to the county would range from $0.93 to $1.75 (DWR 2002). DWR (2002) found that a 1-acre reduction of upland cotton in Colusa County would decrease sales tax revenue returned to the county by about $0.98 (DWR 2002). Effects would occur only in years when the crop idling actions take place, and effects would be less when less land is idled.

11.2.5.4 Effects on Costs Associated with Groundwater

EWA acquisition of water through groundwater substitution and groundwater purchase in the Upstream from the Delta Region and Export Service Area could cause a decline in groundwater levels and increase groundwater extraction costs.

Section 6.2.2 in the Groundwater Resources chapter defines groundwater-level declines to be significant if there is a substantial long-term decline in groundwater levels that results in water-level declines exceeding those experienced historically, or a net reduction in groundwater levels that exceeds basin management objectives established for the basin in question, resulting in adverse third-party and/or environmental effects. Third party effects may include an increase of energy costs to users, as more energy is needed to extract the groundwater at a greater depth. Well yields may also diminish, adversely affecting water supply to third-party users. Decreased yields may cause the third-party user a reduction in crop yield or further increase production costs if farmers choose to apply optimal amounts of irrigation water to retain high yields.

The groundwater mitigation measures are designed to reduce adverse effects by requiring a preliminary review of the existing local groundwater levels and extraction wells prior to the transfer. These measures, however, do not guarantee that all adverse effects would be avoided and further stipulate that all sellers have a monitoring and mitigation program to address adverse effects. These programs provide assurances that substantially adverse effects resulting from groundwater transfers to the EWA Program would be identified, assessed, and mitigated for at a local level.

Furthermore, the groundwater mitigation measures recommend that each local mitigation program include a financial strategy for funding appropriate mitigation measures. Mitigation costs may encompass, but are not inclusive to the following: (1) costs associated with providing an alternative water supply if well yields substantially decrease or pumping curtailment is required until natural recharge

raises water levels, (2) costs of lowering pumping bowls or deepening wells, and (3) reimbursement for substantial increases in pumping costs that are incurred by third party groundwater users. Expenses incurred from groundwater effects are the responsibility of the local seller, unless an alternative agreement has been made between the seller and purchasing agency.

Groundwater storage by the EWA agencies would increase groundwater levels, resulting in less pumping energy required to extract water for third-party users. Raising groundwater levels would reduce extraction costs.

11.2.5.5 Effects on Water Transfer Market Prices

EWA water transfers could reduce the availability of water transfers and, by increasing demand increase the price and cost of water transfers for other water users. In economic theory, if the demand for water transfers increases, the price might also increase. The extent to which price might increase with EWA purchases depends on the size of the transfer and the shape of the water transfer supply function.

This type of effect could be important for other water users, who sometimes buy water to augment their supplies, and for water acquisition programs that buy water for environmental purposes. In particular, the CVP Level 4 refuge water supply program buys water to meet requirements in CVPIA Section 3406(d)(2).[15] If water prices were increased, and the budget for purchasing Level 4 supplies were fixed, then less refuge water supply could be purchased. Water transfer market price effects could affect all EWA regions. Potential price increases to municipal water districts, such as Metropolitan Water District, could be transferred to consumers in Southern California through higher water rates.

In recent years, more buyers and sellers have participated in water transfers. Water demand in cities is growing and some supplies have been reduced by environmental and administrative decisions. These factors have caused water agencies to seek new sources of water to meet their demands. At the same time, the amount of water transfers for environmental purposes has increased.

Table 11-40 summarizes water transfer volumes purchased for various uses since 1995.

[15] Chapter 1 and Chapter 2 discuss requirements of Refuge Level 4 water demands.

Table 11-40
Water Purchases by Type of End User
(Acre-feet)

Year	Total	Environmental	M&I	San Joaquin Valley Farmers	Other Farmers	Mixed Purpose
1995	511,904	111,899	112,667	279,331	8,007	0
1996	825,185	72,216	220,308	503,548	29,113	0
1997	1,037,808	293,000	191,402	439,322	14,084	100,000
1998	554,411	61,748	215,956	211,029	65,678	0
1999	1,078,379	229,459	173,988	556,980	75,592	45,360
2000	1,281,305	276,290	169,826	507,841	94,146	233,202
2001	1,257,117	445,543	261,922	388,401	112,776	48,475

Source: Public Policy Institute of California 2002

Table 11-40 shows that environmental transfers were not a large share of total water transfers in the market from 1995 to 2000. In 2001, the share of environmental transfers increased to about one-third of all transfers. Not all the 2001 environmental transfers were EWA acquisitions (PPIC 2002).

The discussion and conclusions below are based on the short history of the EWA and the water transfer market in California. The EWA has been active in the water transfers market only since 2001. In 2001, EWA Project Agencies paid prices ranging from $75 to $100 Upstream from the Delta Region and $138 to $360 in the Export Service Area (Water Transfers Office 2003a). In 2002, EWA Project Agencies paid $75 for water transfers in the Upstream from the Delta Region and $181 in the Export Service Area (Water Transfers Office 2003).

In the future, the EWA would not likely account for a large share of total water transfers in most years. Other buyers, especially agricultural users, typically buy more water, and M&I buyers are likely to be more important in the future. In some years, if and when EWA purchases up to 600,000 AF, the EWA could account for a larger share of the water transfer market. During these years, the EWA could influence water prices.

The water transfer supply function describes the relationship between price and quantity of water transfers supplied. It shows how much more water would be provided by sellers as the price of water increases. Supply elasticity is the percentage increase in quantity of a good or service supplied divided by a small percent change in price offered for that good or service. For an inelastic supply, price does not have much effect on quantity supplied. A 1 percent increase in price would increase the quantity supplied by a smaller percentage. For an elastic supply, price has a relatively large effect on quantity supplied. The same 1 percent increase in price would increase the amount of water transferred by more than 1 percent. If supply is elastic, increases in transfer demand have little effect on price because more water is readily made available for sale at the going price.

Two factors are very important in determining the elasticity of water transfer supply. One factor, which pertains to water transfers from idling land, is the amount and quality of agricultural land that could be idled. If the amount is large and the quality is very similar, then a large amount of land would give up a similar per-acre net return by participating in water transfers and the water transfer supply would be relatively elastic. In California, this factor should contribute to a relatively elastic water transfer supply. California has large amounts of similar rice and cotton land, relative to the transfer market size, and EWA water acquisitions would only idle up to 20 percent of that land.

The second factor pertains to water transfers from surface or groundwater. Supply is more elastic if more surface and groundwater can be supplied economically in response to higher prices. In general, the amount of groundwater and surface water capacity is also large relative to the water transfer market.

In economic theory, long-run supply is more elastic than short-run supply because some adjustments that sellers make to respond to higher prices take time. For example, investments to develop new supplies or conserve water take time to plan and implement. The amounts of intentional groundwater recharge and other new supplies available for transfer are growing, in part, because buyers are willing to pay for them, but these improvements tend to lag behind the demand for them.

Figure 11-5a illustrates examples of demand and supply curves in the water transfers market. If demand increases, the demand curve would shift to the right, as shown on Figure 11-5b, resulting in an increase in price. In this example, supply is elastic so the increase in price is small relative to the increase in demand.

The factors potentially affecting long-run supply discussed above would result in shift of the supply curve to the right and make it even flatter – more elastic. More water supply would shift the supply function and drive down the price of transfers.

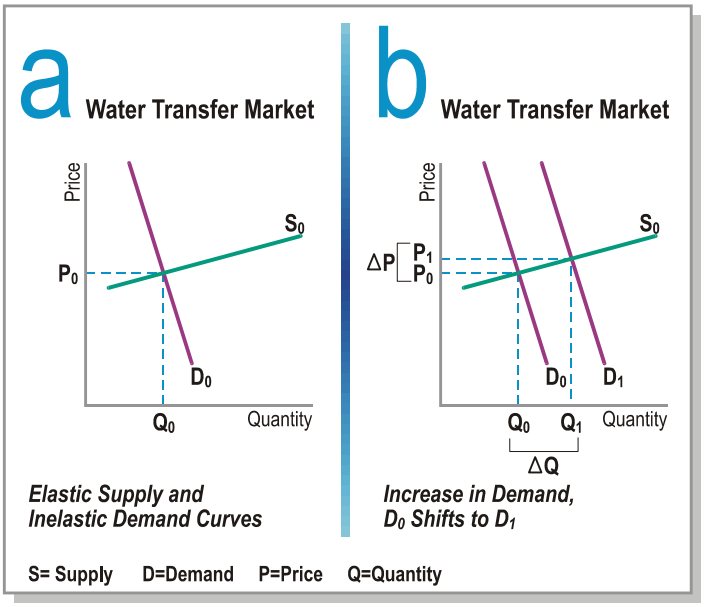

Figure 11-5
Supply and Demand in the Water Transfers Market

The supply function also shifts from year to year as underlying factors change. Hydrologic conditions and agricultural prices are both important underlying factors. These factors could affect water transfer prices much more than water transfer demand. The difference in available supply between a wet year and a dry year

amounts to millions of acre-feet. Dry hydrologic conditions probably had an upward influence on water prices in 2001. Small changes in agricultural prices can also have a large effect on water transfer supply because net returns in farming are very responsive to agricultural prices.

The water purchases by EWA Project Agencies in 2001 did not appear to increase water transfer prices. Prices in 2002 for major water transactions actually decreased on average from 2001 (Stratecon Inc. 2003). However, other factors such as the location of water purchases may have been important in the reduction of prices from 2001 to 2002.

The water transfer price data in Figure 11-4 and the amount of water purchases as shown in Table 11-41 suggest that water transfer prices are not determined by the amount of water purchased. Rather, water transfer prices are more closely related to underlying hydrologic conditions and conditions in agricultural markets.

The discussion above suggests that (1) water transfer supply may be fairly elastic in California, and (2) hydrologic conditions and agricultural prices have more influence on water transfer prices than the amount of water transfer demand.

In summary, EWA water acquisitions could increase water transfer prices; however, effects in a typical water year would not likely be substantial. The water transfer market in California is developing, so the amount of increase that may occur under different amounts and locations of water purchases is very uncertain. Several factors are important when considering price effects caused by EWA acquisitions:

1. Whether the EWA accounts for a large share of the water transfer market in most years.

2. Elasticity of supply in the water transfer market means that increasing demands would not necessarily have much upward effect on prices.

3. Variability in water transfer prices over time might have little to do with the amount of water bought by the EWA or other buyers. Rather, hydrologic conditions and agricultural prices probably have more effect on the price of water transfers. These factors are not controlled by participants in the market.

For reasons discussed above, the amount of price effect and its subsequent adverse effect cannot be predicted at this time. In particular, the amount and location of future water transfers are not known.

11.2.5.6 Effects of Multi-Year Water Transfers

EWA Project Agencies could negotiate multi-year water transfers with willing sellers. The project description specifies that an EWA acquisition would not result in idling of more than 20 percent of available rice or cotton acreage in a county or region. The effects on value of output, value added, wages and salaries, and employment

described above represent annual effects. A multi-year purchase would produce some economic effects above the sum of effects for the individual years. Fixed expenses for farmers would change some during multi-year water transfers. For example, a 1-year transfer would probably not affect a farmer's decision to invest in machinery, but a multi-year transfer may.

Conversely, farmers participating in multi-year transfers would plan on returning the land to production after the transfer. Therefore, some fixed expenses might be deferred, but not avoided. To the extent that capital and replacement expenses would be deferred and not canceled, long-run effects of multi-year transfers at the farm level would be about the same as annual transfers.

In the long-run, a multi-year water purchase should not produce any economic effects in the off-farm agricultural industry above those that would occur annually. DEIM assumes that fixed expenses in farm-related businesses change as they adjust to new, long-run level of output. The infrastructure that supports the region's agricultural industry could be reduced in the long-run, but, relative to a scenario with annual transfers only, additional off-farm reduction occurs only if farms engaged in multi-year transfers decide to cancel (not defer) their capital and replacement expenses.

11.2.6 Environmental Consequences/Environmental Impacts of the Fixed Purchase Alternative

The Fixed Purchase Alternative specifies purchases of 35,000 acre-feet from the Upstream from the Delta Region and 150,000 acre-feet from the Export Service Area. While the amounts in each region are fixed, the acquisition types and sources could vary. In this section, the effects of each potential transfer are analyzed to allow the EWA Project Agencies maximum flexibility when negotiating purchases with willing sellers. These transfers are the same actions as those described in the Flexible Purchase Alternative, but the amounts are limited by the total acquisition amount in each region (35,000 acre-feet from the Upstream from the Delta Region and 150,000 acre-feet from the Export Service Area). As in the Flexible Purchase Alternative, crop idling and groundwater substitution would be EWA actions with potential regional and agricultural economic effects; and all water acquisitions could affect prices in the water transfer market.

11.2.6.1 Crop Idling

Crop idling acquisitions under the Fixed Purchase Alternative would have the potential to idle approximately 15,000 acres of rice in the Upstream from the Delta Region in Glenn, Colusa or Yolo Counties and 10,600 acres in Placer, Sutter or Butte Counties. The difference in acreages among the counties is caused by conveyance and storage issues in Lake Shasta and the Sacramento River (see Chapter 2). A total of 65,000 acres of cotton would be idled in the Export Service Area to acquire the total 150,000 acre-feet. The effects described in Section 11.2.5, Flexible Purchase Alternative, represent the effects on regional, county, and local economies for maximum land idling actions as determined by the 20 percent crop idling measure of

the project description. The Fixed Purchase Alternative is also limited by the 20 percent crop-idling measure. The Fixed Purchase Alternative analysis assumes that it would be possible to purchase the entire 35,000 acre-feet or 150,000 acre-feet of water in a single county, if the 20 percent of baseline acreage is not reached first. This assumption is made to allow the EWA agencies to purchase available water in a county. It would be unlikely that the EWA agencies would acquire the entire 35,000 acre-feet or 150,000 acre-feet from a single county, and this analysis is only demonstrating that it could be possible. However, even though it is possible, the EWA will try to spread purchases across a larger area.

EWA acquisition of water via crop idling of would increase net revenues to individual farmland owners participating in the EWA.

Effects to farmland owners would be similar to those described under the Flexible Purchase Alternative. Farmland owners who participate in the EWA would receive higher expected net revenues from the sale of water than what they would receive from farming the land.

EWA acquisition of water via crop idling would decrease net revenues to some tenant farmers whose landowners choose to participate in the EWA.

Effects to tenant farmers under the Fixed Purchase Alternative would be the same as described in the Flexible Purchase Alternative.

EWA acquisition of water via crop idling of rice acres in the Upstream from the Delta Region would decrease the total value of output, value added, wages and salaries, and employment in the region.

In the Upstream from the Delta Region, it would be possible to acquire the entire 35,000 acre-feet of water in a single county if 15,000 acres (or 10,600 acres in Placer, Sutter, or Butte Counties) were below the 20 percent crop idling measure. Table 11-31 (Section 11.2.5) describes the maximum rice idling actions in each county in the Upstream from the Delta Region. If the acres of rice idled under the Flexible Purchase Alternative were greater than 15,000 acres (or 10,600 acres), then the Fixed Purchase Alternative would idle only 15,000 acres (or 10,600 acres) as the maximum EWA action. If the maximum acres idled were less than 15,000 acres (or 10,600 acres) because of 20 percent crop idling limits, then the Fixed Purchase Alternative would include the same acreage as the Flexible Purchase Alternative as the maximum EWA action. Table 11-41 summarizes the rice acres idled in the Fixed Purchase Alternative. (Values associated with the percentages are presented in Table 11-43.)

Table 11-41
Economic Effects of Rice Idling under the Fixed Purchase Alternative
Upstream from the Delta Region

	Rice Idling Action			Percent Economic Effect[3]			
County	Total Rice Acres[1]	Maximum Idled Acres[2]	% of Total Acres Idled	Value of Output	Value Added	Wages and Salaries	Employment
Butte	95,120	10,600	11.1%	-0.47%	-0.30%	-0.28%	-0.33%
Colusa	132,338	15,000	11.3%	-2.74%	-2.07%	-2.53%	-2.50%
Glenn	83,777	15,000	17.9%	-1.87%	-1.74%	-1.91%	-2.80%
Placer	16,379	3,280	20.0%	-0.04%	-0.03%	-0.03%	-0.05%
Sutter	96,722	10,600	10.9%	-0.61%	-0.43%	-0.49%	-0.61%
Yolo	23,822	4,770	20.0%	-0.14%	-0.09%	-0.08%	-0.11%
Maximum acres available	448,158	59,250	13.2%				

Source: DEIM 2002

(1) The figures representing total rice acres within the counties are based on a five-year average to take into account any recent land trends in rice production. The data is taken from the County Agricultural Commissioners Reports from 1995 to 1999.

(2) In order to avoid limiting potential land idled a single county, the Fixed Purchase Alternative analysis assumes that it is possible to purchase the entire 35 TAF from one county. Therefore, these are the maximum acreages available for the Fixed Purchase Alternative in each county. It is important to note, EWA agencies only seek to acquire maximum 35 TAF water and would not likely acquire all water in an individual county.

(3) These percentages represent reductions to baseline values.

EWA acquisition of water via crop idling of cotton acres in Fresno, Kern, Kings, and Tulare Counties would decrease total value of output, value added, wages and salaries, and employment in each county.

The Export Service Area analysis for the Fixed Purchase Alternative uses a similar approach as the Upstream from the Delta Region. In the Export Service Area, it would be possible to acquire the entire 150,000 acre-feet of water in an individual county if 65,000 acres of cotton in the county were below the 20 percent crop idling measure. Table 11-39 describes the maximum cotton-idling actions in each county. Twenty percent of cotton acreage was more than 65,000 acres as in Fresno County, so the Fixed Purchase Alternative could include all 65,000 acres as the maximum EWA action in that county. In the other counties, 20 percent of cotton acreage was less than 65,000 acres, so the Fixed Purchase Alternative included only 20 percent of cotton acreage as the maximum EWA action for the county. Table 11-42 shows the maximum cotton acres idled in each county in the Fixed Purchase Alternative. Values associated with the percentages are presented in Table 11-43.

Table 11-42
Economic Effects of Cotton Idling under the Fixed Purchase Alternative
Export Service Area

Cotton Idling Action				Percent Economic Effect[3]			
County	Total Cotton Acres[1]	Maximum Idled Acres[2]	% of Total Acres Idled	Value of Output	Value Added	Wages and Salaries	Employment
Fresno	352,880	65,000	18.4%	-0.38%	-0.18%	-0.20%	-0.26%
Kern	246,616	49,300	20.0%	-0.33%	-0.16%	-0.19%	-0.25%
Kings	222,543	44,500	20.0%	-1.62%	-0.80%	-0.88%	-1.40%
Tulare	92,680	18,500	20.0%	-0.22%	-0.11%	-0.14%	-0.16%
Maximum acres available	914,719	177,300	19.4%				

Source: DEIM 2002

(1) The figures representing total cotton acres within the counties are based on a five-year average to take into account any recent land trends in cotton production. The data is taken from the County Agricultural Commissioners Reports from 1995 to 1999.

(2) In order to avoid limiting potential land idled a single county, the Fixed Purchase Alternative analysis assumes that it is possible to purchase the entire 150 TAF from one county. Therefore, these are the maximum acreages available for the Fixed Purchase Alternative in each county. It is important to note, EWA agencies only seek to acquire maximum 150 TAF water, or 65,000 acres and would not likely acquire all water in an individual county.

(3) Percentages represent reductions to baseline values.

EWA acquisition of water through crop idling could change county property and sales tax revenues.

County tax revenues would be less affected under the Fixed Purchase Alternative because less land would be idled. Agricultural land use mitigation measures continue to apply under the Fixed Purchase Alternative; therefore, property tax and subvention revenues would not be reduced. Agricultural and retail stores would lose some sales, so sales taxes would be reduced though not as much as under the Flexible Purchase Alternative.

11.2.6.2 Groundwater Pumping Costs

EWA acquisition of water through groundwater substitution and groundwater purchase in the Upstream from the Delta Region and groundwater substitution, groundwater purchase, and groundwater storage in the Export Service Area could cause a decline in groundwater levels and increase groundwater extraction costs.

Groundwater acquisitions would be further limited under the Fixed Purchase Alternative, relative to the Flexible Purchase Alternative. Groundwater transfers to the EWA Program would be identified, assessed, and mitigated for at a local level. Furthermore, if necessary, a local mitigation program would include a financial strategy for funding appropriate mitigation measures. This would protect users from any increases in energy or pumping costs.

11.2.6.3 Water Transfer Market Prices

EWA water transfers could reduce the availability of water transfers and increase the price and cost of water transfers for other water users.

Under the Fixed Purchase Alternative, EWA Project Agencies would limit water acquisitions. EWA would also not be as large of a participant in the market. Therefore, EWA would have less demand for water transfers and, therefore, less effect on the price of water.

11.2.7 Comparative Analysis of Alternatives

This chapter has thus far analyzed the economic effects of potential EWA water transfers which represent the "worst-case scenario" that could occur if all acquisitions were made in a single year. This approach ensures that all effects of transfers are included, and provides the EWA Project Agencies the flexibility to choose transfers that may be preferable in a given year. The EWA, however, would not actually purchase all of this water in the same year. The following paragraphs provide information about how the EWA would more likely operate in different year types.

Under the No Action/No Project Alternative, historic farming practices would continue in wet and dry years. Farmers may choose to idle more land in dry years, relative to wet years, because of the decrease in water supply for irrigation. Agricultural crop prices would also continue to fluctuate in dry and wet years, resulting in changes in the cropping pattern.

11.2.7.1 Upstream from the Delta Region

In the Upstream from the Delta Region, the Fixed Purchase Alternative would be limited to a maximum acquisition of 35,000 acre-feet from all sources of water. In most years, this amount could be obtained from stored reservoir water purchases. In those years when surface water assets were not available (in part or in total), the EWA agencies would acquire water first from groundwater substitution and/or groundwater purchase, followed by crop idling. The Fixed Purchase Alternative would therefore not likely involve acquisition of water from groundwater substitution or crop idling. Therefore, crop idling effects on local, county, and regional economies, sales tax revenue, and property tax revenue would be minimal, and groundwater pumping costs would likely not increase.

The Flexible Purchase Alternative could involve the purchase of up to 600,000 acre-feet of water from all sources in the Upstream from the Delta Region. EWA agencies would prefer to purchase water from upstream sources because the water would be generally less expensive. The amount that could be purchased would be limited by the excess capacity of the Delta export pumps to move the water to export areas. During wet years, excess pump capacity may be limited to as little as 50,000 acre-feet of EWA asset water because the pumps primarily would be used to export State and Federal project water to Export Service Area users. During dry years, when there would be less CVP and SWP water available for pumping (and therefore the pumps

would have greater availability capacity), the EWA Project Agencies could acquire up to 600,000 acre feet of water from sources in the Upstream from the Delta Region.

The potential for economic effects in the Upstream from the Delta Region during wet years for the Flexible Purchase Alternative would be very similar to the Fixed Purchase Alternative. During wet years, under both alternatives, acquisitions would most likely be from stored water sources, and groundwater substitution and crop idling would not be exercised. During dry year conditions, however, when the export pumps have greater capacity to move EWA assets, groundwater substitution and crop idling would be utilized for additional EWA acquisitions. Therefore, during dry years, under the Flexible Purchase Alternative, EWA Project Agencies would acquire water through groundwater substitution and crop idling at much greater amounts than would occur under the Fixed Purchase Alternative. Increased groundwater substitution and crop idling in dry years would increase the potential for the Flexible Purchase Alternative to have economic effects.

11.2.7.2 Export Service Area

EWA asset acquisitions in the Export Service Area under the Fixed Purchase Alternative would be limited to 150,000 acre-feet from stored groundwater and crop-idling sources. The EWA agencies would purchase stored groundwater first, then purchase water from crop idling if more is needed. Stored groundwater has finite availability, and 150,000 acre-feet would not likely be available in all years. In years with less stored groundwater availability, EWA agencies would turn to crop idling for the remaining water.

EWA asset acquisitions in the Export Service Area under the Flexible Purchase Alternative would be dependent on the water year type in the Upstream from the Delta Region. Export pump capacity during wet years would limit the ability of the EWA Project Agencies to move assets through the Delta, requiring reliance on greater purchase amounts from export area sources. During wet years, acquisitions within the Export Service Area could involve up to 600,000 acre-feet of assets. Much of this water would be from crop idling; therefore, economic effects related to crop idling of the Flexible Purchase Alternative would likely be greater than for the Fixed Purchase Alternative.

Less water would be purchased under the Fixed Purchase Alternative than the Flexible Purchase Alternative regardless of the hydrologic year. Therefore, effects to the water transfer market under the Fixed Purchase Alternative would be less than the Flexible Purchase Alternative.

Table 11-43 summarizes the economic effects of the Fixed Purchase Alternative and the Flexible Purchase Alternative relative to the Baseline Condition.

Table 11-43
Comparison of Regional and Agricultural Economic Effects of Flexible and Fixed Purchase Alternative Compared to the Baseline Condition

Region	***Asset Acquisition or Management***	***Result***	***Effects[1]***	***Maximum Flexible Purchase Alternative Effects[2][3]***	***Maximum Fixed Purchase Alternative Effect[2][4]***
Upstream from the Delta Region and Export Service Area	Crop Idling	Temporary loss of irrigated production and related economic activity	Decrease net revenue to tenant farmers	Tenant farmers could be worse off if landowner sells water	Tenant farmers could be worse off if landowner sells water

Table 11-43
Comparison of Regional and Agricultural Economic Effects of Flexible and Fixed Purchase Alternative Compared to the Baseline Condition

Region	***Asset Acquisition or Management***	***Result***	***Effects[1]***	***Maximum Flexible Purchase Alternative Effects[2][3]***	***Maximum Fixed Purchase Alternative Effect[2][4]***
Kings	Crop Idling	Temporary loss of irrigated production and related economic activity	Reduced economic activity indicated by *(1)* cotton acreage *(2)* county output, *(3)* value added, *(4)* wages and salaries and *(5)* employment	*(1)* 44,500 acres, 20.0% *(2)* $62.2 million, 1.62% *(3)* $17.9 million, 0.80% *(4)* $11.2 million, 0.88% *(5)* 668 jobs, 1.40%	*(1)* 44,500 acres, 20.0% *(2)* $62.2 million, 1.62% *(3)* $17.9 million, 0.80% *(4)* $11.2 million, 0.88% *(5)* 668 jobs, 1.40%
Tulare	Crop Idling	Temporary loss of irrigated production and related economic activity	Reduced economic activity indicated by *(1)* cotton acreage *(2)* county output, *(3)* value added, *(4)* wages and salaries and *(5)* employment	*(1)* 18,500 acres, 20.0% *(2)* $27.2 million, 0.22% *(3)* $7.6 million, 0.11% *(4)* $4.8 million, 0.14% *(5)* 276 jobs, 0.16%	*(1)* 18,500 acres, 20.0% *(2)* $27.2 million, 0.22% *(3)* $7.6 million, 0.11% *(4)* $4.8 million, 0.14% *(5)* 276 jobs, 0.16%
Upstream from the Delta Region and Export Service Area	Crop Idling	Temporary loss of irrigated production and related economic activity	Reduce sales tax revenue to the county	Sales tax revenue would decrease from lower sales in agricultural retail stores.	Sales tax revenue would decrease from lower sales in agricultural retail stores.
Upstream from the Delta Region and Export Service Area	Crop Idling	Temporary loss of irrigated production and related economic activity	Change property tax revenue to the county and reduced subvention payments	Property taxes would increase from higher land values and decrease from change in land classification under Williamson Act.	Property taxes would increase from higher land values and decrease from change in land classification under Williamson Act.
Upstream from the Delta Region and Export Service Area	Groundwater Substitution, Purchase and Storage	Decline in groundwater levels	Increase in groundwater extraction costs	All effects resulting from groundwater transfers would be identified assessed and mitigated for at a local level.	All effects resulting from groundwater transfers would be identified assessed and mitigated for at a local level.
Upstream from the Delta Region, Export Service Area, Delta Region	All	Changes in water transfer prices	Increase in water transfer market prices	Effect would not likely be substantial in a typical water year.	Effect would not likely be substantial in a typical water year.

1) The individual effects, crop acreage, output, value added, wages and salaries, and employment, are hereon referred to by number corresponding to the effect in subsequent columns.
(2) Numbers are presented as reduction in county acreage, total value of output, value added, wages and salaries and employment, followed by percent change to baseline conditions.
(3) The Flexible Purchase Alternative effects presented in the table are based on the county analysis described in section 11.4.6.1 and section 11.4.6.2, and all water comes from idling
(4) The Fixed Purchase is based on the assumption that 50,000 acre-feet of water is to be acquired in the Upstream from the Delta Region and 150,000 acre-feet of water is to be acquired in the export services areas, and all water comes from idling.

11.2.8 Cumulative Effects

11.2.8.1 Crop Idling

11.2.8.1.1 Upstream from the Delta Region

The timeframe for the EWA cumulative analysis extends through 2007. Water transfer programs that also consider crop idling in the Upstream from the Delta Region as a water acquisition method include the Dry Year Purchase Program, the Drought Risk Reduction Investment Program (DRRIP), the CVPIA Water Acquisition Program (WAP) and the CALFED Environmental Water Program (EWP). Transfers negotiated between CVP and SWP contractors and other water users, such as the Forbearance Agreement with Westlands Water District and the recent crop idling acquisition by Metropolitan WD from water agencies upstream from the Delta, are considered part of the Dry Year Program. Chapter 22 provides further explanation of the framework of the cumulative analysis and a summary of the programs considered.

Crop idling in each of these programs is on a voluntary and usually annual basis. Farmers can choose to offer their water for sale to any of the above programs during any season that the programs are in operation, subject to the conditions specified by the programs. The farmers can then decide to resume planting in the subsequent season. The Flexible Purchase Alternative analysis describes the economic effects of idling 20 percent of rice or cotton acres under the EWA on a yearly basis, both in the region and individual counties.

Under the cumulative condition, at the time of the water acquisition, the EWA agencies would consider other reasonably foreseeable transfers by all water transfer programs when determining where to acquire water through crop idling. EWA agencies would then only purchase water from idling 20 percent of the rice land in a county, where this 20 percent would include the other, reasonably foreseeable transfers. If other water acquisition programs purchase more water through crop idling resulting in greater than 20 percent of rice acreage, those programs would be responsible for meeting Water Code requirements and addressing the subsequent cumulative effect. Table 11-44 presents the maximum rice idling acreages by county under 1995 to 1999 economic conditions.

Table 11-44 Acres of Rice Idled under Cumulative Condition	
Upstream from the Delta Region	**Acres idled under Cumulative Condition**
Butte	19,000 acres
Colusa	26,460 acres
Glenn	16,750 acres
Placer	3,280 acres
Sutter	19,340 acres
Yolo	4,770 acres
Total	89,600 acres

Source: DEIM 2002

Land use mitigation measures (discussed in Chapter 13) would limit EWA agencies from purchasing water through crop idling that would affect existing land classifications.

11.2.8.1.2 Export Service Area

Programs that consider crop idling in Export Service Areas cumulatively in conjunction with the EWA include the Dry Year Purchase Program, DRRIP, and the CVPIA WAP. Chapter 22 provides further explanation of the framework of the cumulative analysis and a summary of the programs considered. There are some farmland idling or retirement programs that are not coordinated with the EWA in the Export Service Area.

Under the cumulative condition, at the time of the water acquisition, the EWA agencies would consider other reasonably foreseeable transfers by all water transfer programs when determining where to acquire water through crop idling. EWA agencies would then only purchase water from idling 20 percent of the cotton land in a county, where this 20 percent would include the other, reasonably foreseeable transfers. If other water acquisition programs purchase more water through crop idling resulting in greater than 20 percent of cotton acreage, those programs would be responsible for meeting Water Code requirements and addressing the subsequent cumulative effect. Table 11-45 presents the maximum crop idling acreages by county under 1995 to 1999 economic conditions.

Table 11-45 Acres of Cotton Idled under Cumulative Condition	
Export Service Area County	**Acres Idled under Cumulative Condition**
Fresno	70,500 acres
Kern	49,300 acres
Kings	44,500 acres
Tulare	18,500 acres
Total	182,800 acres

Source: DEIM 2002

The cumulative analysis also considers the Westlands Global Land Settlement Program. The program proposes to retire 200,000 acres of cropland in the Westlands Water District in western Fresno and Kings Counties. Currently, the program does not specify the types and locations of cropland intended for retirement. Westlands Water District issued a policy statement indicating that all sales would be voluntary and third party effects must be identified and addressed. Implementation of this program would change the baseline level of cropland available for idling for EWA Project Agencies. In this instance, EWA Project agencies would not purchase water via crop idling in areas where idling is already larger than historically normal. EWA would not acquire water from crop idling within an area with close economic ties to Westlands Water District until the local agricultural economy has adjusted to the Retirement program.

11.2.8.2 Groundwater Pumping Costs

Water purchases via groundwater substitution by other water acquisition programs, in addition to the EWA, would result in further declines of groundwater levels and higher extraction costs for third-party users. The EWA would continue to implement its groundwater mitigation measures.

11.2.8.3 Water Transfer Market

Growing environmental, municipal and agricultural needs are increasing the demands for water transfers and expanding the water transfers market. Any local or government-sponsored transfer program would contribute to the cumulative condition. More participants in the market might drive up the price of transfers. Increased prices should increase the long-run supply of water for transfer.

Chapter 12
Agricultural Social Issues

California leads the nation in farm production and is a major contributor to the U.S. export trade, exporting more than $12 billion in agricultural products each year. According to the California Department of Food and Agriculture (CDFA 2001), every $1 billion in exports creates approximately 27,000 jobs. In 2000, the value of agriculture production in California exceeded $27 billion (CDFA 2001), and in 1999 the agriculture sector employed approximately 400,000 laborers (Regional Economic Information System[REIS] 1999). In addition to the labor supplied by direct farm employment, many supporting agribusinesses provide employment opportunities. These agribusinesses supply pre- and post-processing operations necessary for crop production, such as transport, storage, retail sales, and marketing. Idling of cropland reduces the employment needs of these businesses. (See Chapter 11 for discussion.)

The ability of a community to withstand the social effects of unemployment is a function of its social well-being. Social well-being involves both community stability issues and environmental justice issues. Although these two categories overlap in many ways, this document describes them separately. This chapter focuses on the effects of crop idling on farm labor and subsequent outcome on community stability. Indicators of community stability include income, poverty, unemployment, and job opportunities. Environmental Justice, Chapter 19, identifies whether Program operations would affect ethnic or low-income groups.

Environmental Water Account (EWA) acquisitions via crop idling could affect community stability. In an idling acquisition, a farmer/landowner would refrain from planting crops for a season and transfer to the EWA agencies the irrigation water normally required for consumptive use. This would reduce the demand for farm laborers. EWA Management Agencies would target rice and cotton for water acquisitions, which require few laborers and large amounts of water relative to other crops. (Refer to Section 19.1.)

12.1 Affected Environment/Existing Conditions

The Affected Environment/Existing Conditions section describes the area of analysis, as pertinent to agricultural social issues. The section then presents regional and county data on community stability measures, followed by specific characteristics of farm laborers. This analysis uses 1999 data to describe existing conditions because it was generally the most current data available.

12.1.1 Area of Analysis

The Agricultural Social Issues analysis divides the State into two regions: the Upstream from the Delta Region and the Export Service Area. The Upstream from the Delta Region comprises counties where potential rice idling may occur, including Butte, Colusa, Glenn, Placer, Yolo, and Sutter. The Export Service Area comprises

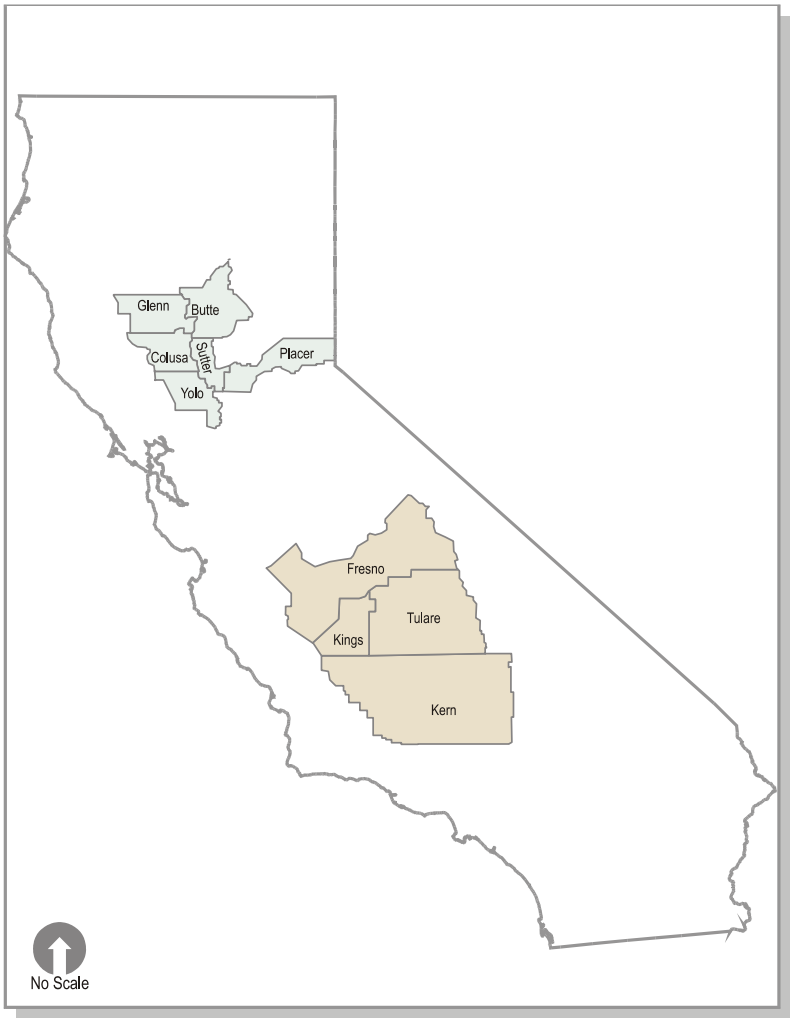

Figure 12-1
Agricultural Social Area of Analysis

counties where potential cotton idling may occur, including Fresno, Kern, Kings, and Tulare. The boundaries of each county in each region define the Upstream from the Delta Region and the Export Service Area. (Refer to Figure 12-1.) Counties selected for potential idling contain extensive rice or cotton acreage and irrigation districts that are willing to participate in the EWA Program. (Refer to Chapter 2 for further discussion.)

12.1.2 Community Stability

The ability of a county or community to absorb job losses is a function of its economic diversity and social well-being. Social well-being involves both community stability and environmental justice issues. Chapter 19 discusses Environmental Justice issues. The following discusses economic indicators of community stability.

Economic indicators of community stability include:

- Population
- Median income
- Per capita income
- Poverty rate
- Unemployment rate

Median family income[1] measures the annual income received by an average family living within a household. The larger the median family income of the county, the more income tax revenue is generated, which can be used to provide community

[1] The median level is the point for which one-half of the income observations are above and one-half of the income observations are below.

services for the unemployed. For example, the relatively high median incomes in Placer County provide taxes that help stabilize the community against unemployment effects. In 2000, Placer County's agricultural industry (generally a low-income industry) employed less than 3.5 percent of the civilian workforce, and trade and service industries (higher income industries) employed over 50 percent of the workforce (DOF 2000). Unemployment rate was a relatively low 3.2 percent (DOF 2000).

Per capita income is the total of all wages, interest, rents, and other incomes divided by the number of people in the county. In Yolo County, people earn high per capita incomes, relative to other counties in the Region. Again, taxes on higher incomes provide relatively more compensatory social services to offset unemployment effects and contribute to social stability.

The percentage of people living below poverty level is also a measure of community stability. Counties experiencing high poverty rates earn less revenue per capita than those with lower poverty rates. These counties must provide more services for the economically disadvantaged and have fewer resources.

The last economic indicator that influences community stability is unemployment rate. A high unemployment rate increases the demand for more social services, which the county is expected to supply. In Colusa County, the 1999 unemployment rate was relatively high (15.9 percent). Colusa's unemployment rate, coupled with its low per capita income, represents a less stable community structure that is less effective in buffering employment loss than other counties with lower employment rates (California Economic Development Department [EDD] 1999).

California has an infrastructure in place that buffers the needs of the unemployed. As shown in Tables 12-2 and 12-3, the average number of unemployed varies between each county. Programs offering services include, but are not limited to, *Experience Works* that provides training for mature workers, as well as public programs that include MediCal, CalWORKS, food stamps, regional occupational training programs, and others. These programs would likely offer services to individuals displaced by crop idling. Interviews with individuals involved with farm labor indicate that the services offered do not include affordable medical insurance coverage, and generally displaced farmworkers find it difficult to meet the most basic financial obligations of rent and utilities. Therefore, displaced farmworkers would most likely require financial supplements to cover fixed expenses and medical insurance (Quiroga-Valvodinos 2003; Clayton 2003).

Factors affecting social well-being of the unemployed also include steady employment and job guarantees. Job guarantees are influenced by seasonal and economic changes. Natural conditions can lengthen or shorten employment (e.g., water shortages can reduce the number of acres farmed). The effect of natural occurrences on farm labor in the past is a component of the assessment. (See Section 12.3.1 Assessment Methods.)

In general, stable communities are typically areas that collect sizable tax revenues and have large urban centers with broad-based economies more capable of providing an assortment of public services, including unemployment compensation. The large and diverse industries of urban centers provide job opportunities, income, and tax revenues that serve to stabilize the communities. These more stable communities are identified by sizeable median incomes, low unemployment, and the number of re-employment opportunities. Conversely, a less stable community would be a smaller county, city, or local government with smaller economic base, higher unemployment, fewer re-employment opportunities, limited social services, and fewer revenues. Unemployment has a larger effect on these communities.

12.1.3 Regional Community Stability

Community stability statistics help identify areas more sensitive to crop idling. Table 12-1 details regional economic indicators pertaining to community stability in the counties where crop idling may occur. The population in the Upstream from the Delta Region areas earns higher median and per capita incomes than those in the Export Service Area, which have greater poverty[2] and unemployment[3] rates than Upstream of the Delta Region.

Table 12-1
Existing Conditions: Regional Demographics and Economic Indicators of Social Well-Being

	Upstream of the Delta Region	***Export Service Area***
1999 Population[(1)]	713,873	1,887,275
Average Median Family Income[(2)]	$39,295	$34,975
Average Per Capita Income[(1)]	$24,891	$19,023
Average Poverty Rate[(3)]	15.6%	21.8%
1999 Average Unemployment Rate[(4)]	9.1. %	13.6%
Unemployment Range[(2)]	3.2% - 15.9%	11.4% - 16.5%

Counties in the Upstream from the Delta Region include Glenn, Colusa, Yolo, Butte, Sutter, and Placer; counties in the Export Service Area include Fresno, Kings, Kern, and Tulare.

(1) REIS, 1999
(2) U.S. Census Bureau,1999
(3) U.S. Census State and County QuickFacts, 1999
(4) 4 EDD, 1999

2 Poverty rates are expressed as a percentage of households in the county living at the poverty level or below. The U.S. Census Bureau defines poverty thresholds (levels of income) for families of various sizes and compositions. U.S. Census Bureau information for a family of five is consistent with data indicating that the majority of farmworkers' families are comprised of five individuals. In 1999, an annual income of $19,882 represented the U.S. Census Bureau poverty threshold for a family of five including three related children under 18 years of age; in California the poverty level for a family of five is a little higher, ranging between $22,940 and $24,160 (California Economic Development Department [EDD], 1999).

3 The U.S. Census Bureau defines the unemployment rate as the percent of the civilian labor force (all civilians 16 years of age and over) that is unemployed.

12.1.4 Environmental Measures Incorporated into the Project Description

In order to avoid or decrease adverse social effects on community stability, the EWA would incorporate the following measures as part of the program definition.

1) EWA agencies would not purchase water via crop idling if more than 20 percent of recent harvested rice or cotton acreage in the county would be idled through EWA water acquisitions. (Refer to Section 11.2.8 for discussion of additional water acquisition programs.) The EWA would idle less than 20 percent if other reasonably foreseeable transfers under other programs are idling land).

2) EWA agencies would also acquire less water by crop idling when the level of land idling is already larger than historically normal.

Social effects of land idling are exacerbated when an unusual amount of land is already being idled. Therefore, idling less land in a local area when the amount of land idling is already more than historically normal would lessen economic effects.

12.1.5 Upstream from the Delta Region

Rice crop idling in the Upstream from the Delta Region would generally occur during dry years, when the Delta has the capacity to transfer the water. Rice is a major commodity in the upstream from the Delta counties of Glenn, Butte, Placer, Colusa, and Yolo. In 2000, milled rice in Butte County contributed 18 percent to California's rice income (CAC 2000). Of the region's 713,873 people, approximately 23,900 (3.3 percent) are farm laborers (REIS 1999). Table 12-2 contains additional information about these counties. The number of farms in each county is given as a general indicator of potentially available farm labor opportunities.

Table 12-2
Upstream Counties- Population, Income, Employment, and Farms

County	Population [1]	Median Income [2]	Per Capita Income [1]	Poverty Rate [2]	Unemployment Rate [3]	Average Number Unemployed (1990-2001) [5]	Average Number of Farms between 1987-1997 [4]	Average Farm Acreage in County [4]
Butte	195,220	$31,924	$22,012	20.9%	6.8%	7,536	1,772	450,347
Colusa	18,844	$35,062	$23,085	18.1%	15.9%	1,589	803	445,820
Glenn	26,328	$32,107	$18,015	19.9%	11.2%	1,589	1,182	482,411
Placer	34,972	$57,535	$34,972	7.7%	3.2%	5,482	1,118	148,514
Sutter	78,423	$38,375	$24,223	17.2%	13.0%	5,477	1,371	340,826
Yolo	155,573	$40,769	$27,037	15.8%	4.3%	5,314	949	520,366

12.1.6 Export Service Area

Cotton crop idling generally would occur more in the Export Service Area during wet years, due to decreased Delta transfer capacity. Cotton crop idling in the Export Service Area would occur in Fresno, Kings, Tulare, and Kern Counties. Fresno County contains some of the most productive agricultural land in the country and earns some of the highest dollar values in agriculture in the State of California. Of the region's 1,887,275 people, 12,320 (0.7percent) were farm laborers (REIS 1999). Table 12-3 contains additional information on these counties.

Table 12-3
Export Service Area Counties- Population, Income, Employment and Farms

County	Population [1]	Median Income [2]	Per Capita Income [1]	Poverty Rate [2]	Unemployment Rate [3]	Average Number of Farms between 1987-1997 [4]	Average Number of Farms between 1987-1997 [4]	Average Farm Acreage in County [4]
Fresno	763,069	$34,725	$21,146	25.6%	13.4%	50,792	7068	1,877,151
Kern	642,495	$35,446	$19,886	21.0%	11.4%	35,215	2082	2,909,354
Kings	123,365	$35,749	$15,732	23.6%	13.1%	8,178	1125	711,656
Tulare	358,470	$33,983	$19,329	27.9%	16.5%	34,723	5609	1,357,986

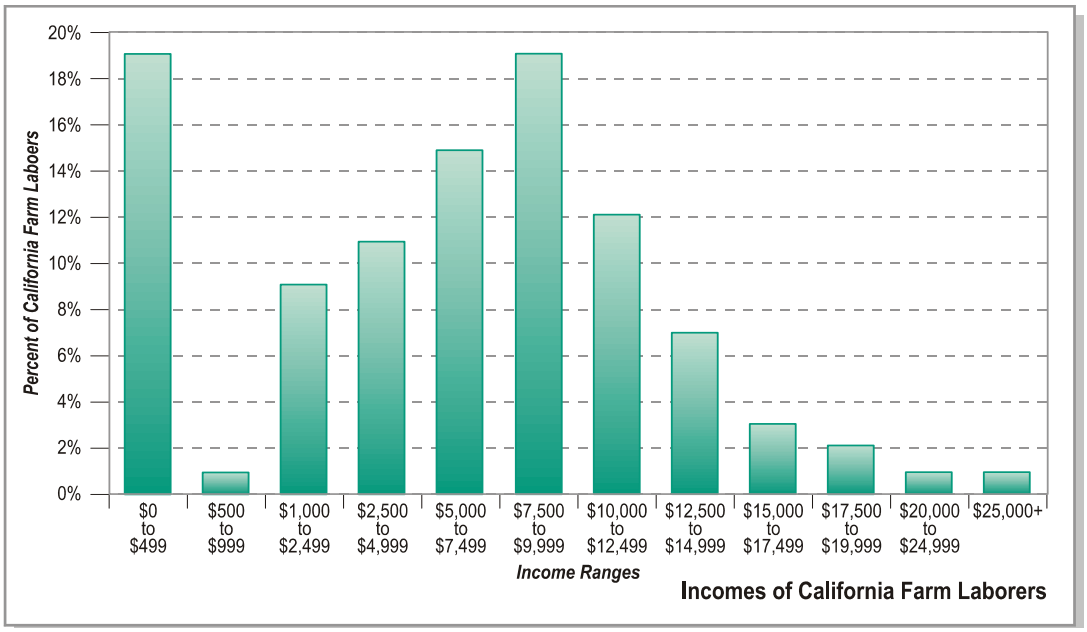
(4) U.S. Department of Agriculture 1997
(5)EDD Labor Market Information, 1990-2001

12.1.7 Characteristics of Farm Laborers

The above information presents community stability measures of all sectors of the regional and county economies. Farmworker median incomes and per capita incomes typically represent a fraction of the values identified in Tables 12-1, 12-2 and 12-3. The following is a list of characteristics particular to farm laborers (Rosenberg, et al, 1998) that provide a better understanding of the potential agricultural social effects of crop idling.

- Nearly all farm laborers are foreign born and 93 percent are of Hispanic descent.
- Forty percent of farm laborers do not have legal authorization to work in the U.S.
- The average age of a farm laborer is 33.
- Sixty percent are married, and more than half have children. Farm laborers who are parents have an average of three children.
- Eighty-two percent of farm laborers are male and have a median education level equivalent to the sixth grade.
- Median annual total family income for California crop workers is between $7,500 and $10,000



Anecdotal evidence gathered from the California Rice Commission and cotton farms (Schmidt 2002; McCorkle 2002; Davenport 2002) indicate that laborers possess mechanical skills and normally return every season. The laborers are stable employees who are generally not migrant in nature. Cotton farm laborers' annual income fluctuates about the poverty level, but may increase based upon employees'

skill level and desire to work. The cotton season runs between late March and November. The rice season begins in May and runs through November, unless workers remain employed until February to assist in exporting the rice crop.

12.1.7.1 Environmental Justice

The above information indicates that farm laborers are mainly low income and minority. Environmental Justice (Chapter 19) focuses on effects to the low income and minority population. A recent National Agricultural Workers Survey (Rosenberg 1998) provides a thumbnail sketch of California's agricultural workers and verifies that California is heavily dependent upon foreign workers, especially those from Mexico. According to the survey, 91percent of California's crop workers were born in Mexico, compared to 82 percent in 1990-91.

Surveyors use incrementally increasing income ranges to analyze farmworker wages, as shown on Figure 12-2. Survey results show that the median total family income for

(Rosenberg 1998)

Figure 12-2
Annual Incomes of California Farm Laborers

California farm laborers ranged from $7,500 to $10,000. Unauthorized workers earn a median income that ranges from $2,500 to $5,000. According to family size and income, 61 percent of California's farmworking families live in poverty – a percentage that is increasing (Rosenberg 1998). Because of the farmworker profile, crop idling could have disproportionate effects on low income and minority farmworkers. Rather than focusing on these issues, this agricultural social effects analysis focuses on the farm laborer population and employment opportunities. Chapter 19 contains a full explanation of EWA effects on low income and minority groups.

12.2 Environmental Consequences/Environmental Impacts

12.2.1 Assessment Methods

A number of factors affect the EWA agencies' ability to transfer water, i.e., price, water availability, and location affect contract negotiations with willing sellers. These limiting factors change from year to year; therefore, EWA Project Agencies may choose to vary their acquisition strategy annually. With the intent of providing the EWA Project Agencies the greatest flexibility, the following text describes the potential effects on farm laborers with maximum idling actions in both the Upstream from the Delta Region and Export Service Area.

This assessment compares the projected agricultural social effects of potential EWA actions to the Baseline Condition. The Baseline Condition description for this assessment employs 20 years of farm labor employment data (between 1980 and 1999) to identify farm labor employment trends. These employment patterns would likely continue into the future. The 20-year period of analysis incorporates variations in weather and economic conditions over time. Additionally, this analysis considers the effects of seasonal fluctuations at the general level, acknowledging that conditions that may affect one farm adversely may have minor or no effects on a neighboring crop.

This 20-year data analysis was also chosen to identify historic fluctuations in farm labor as a means of voluntarily assessing potential adverse effects, though neither 40 CFR 1505.2 nor 40 CFR 1508.14 require mitigation of adverse social effects. Although NEPA does require a discussion of social effects if they are related to the natural or physical environment, it does not require a threshold of significance. Similarly, CEQA does not consider project related economic or social changes as adverse effects on the environment that would require mitigation.

For consistency of analysis, 1999 conditions serve as the basis for impact determination throughout the analysis. An ordinary least square regression identifies each counties' farm labor employment trends[4]; and standard deviations[5] of the trend reflect annual, seasonal, and economic fluctuations. In counties that exhibit no increasing or decreasing farm labor employment trends, standard deviations of the historic average represent annual seasonal and economic fluctuations. Standard deviations derived for both trends and averages define the baseline against which to measure EWA –generated farm employment changes. This analysis uses average number of workers per 1,000 acres of idled crops to estimate the changes in

4 90 percent significance.

5 Standard deviations define the dispersion of data around the mean. Assuming data are normally distributed, 68 percent of the data will fall within one standard deviation of the mean.

employment that could be caused by EWA crop idling[6]. The comparison of EWA changes with the standard deviation of averages or standard deviation of the trends in the Baseline Condition determines whether crop idling produces unemployment beyond natural, seasonal, or economic-related actions.

The estimates of full-time farm worker jobs represent a portion of the total job loss calculated in Chapter 11. The balance of the jobs lost, as described in Chapter 11, would also affect job classifications other than farm workers.

12.2.2 Environmental Consequences/Environmental Impacts of the No Action/No Project Alternative

The No Action/No Project Alternative describes future conditions during Stage 1 of CALFED, if the EWA did not exist. With the exception of Placer County, farmworker employment during this assessment period would either remain the same or increase. Farmers would continue to temporarily idle some land due to land practices and market issues, while other farmers would place previously idled land back into production. The continued rotation of these farming practices would cause some fluctuations in agricultural employment, but those changes would likely reflect that of the employment fluctuations described in the affected environment section.

Additionally, several CALFED and other government sponsored programs would idle land for restoration and habitat purposes. This would permanently take agricultural land out of production. (Refer to Section 12.2.6.)

The analysis of agricultural employment for Placer County indicates that a urbanization would result in a decline to 1240 farm laborers in 2004 from 1720 employed farmworkers in 1983 (REIS). The No Action/No Project alternative would not alter this trend and thus, would have no effect on agricultural social issues for the county. The No Action/No Project Alternative would have no bearing on positive farm labor employment trends in Colusa, Yolo, Butte, Sutter, Fresno, Kern, and Tulare counties. (Refer to Section 12.2.5.)

12.2.3 Environmental Consequences/Environmental Impacts of the Flexible Purchase Alternative

The Flexible Purchase Alternative allows transfers of 600,000 acre-feet and does not specify transfer limits in the Upstream from the Delta Region or in the Export Service Area. The potential for crop idling actions in the Upstream from the Delta Region is greater during dry years when Delta pumping availability allows EWA agencies

---

[6] University of California Cooperative Extension Crop Budgets 1999 and 2001. Average number of full-time workers per 1,000 acres includes both machine and nonmachine labor. Because the forty-inch row alcala variety is more commonly planted than the thirty-inch row, the labor equation assumes that 66 percent of the cotton is of the 40-inch row variety, and 33 percent is the 30-inch row alcala variety. A weighted average of the two varieties establishes that 6.6 labor equivalents are required for every 1000 acres of cotton. Full time is assumed to be 2000 hours per year. Every 1000 acres of rice requires 2.7 full-time labor equivalents.

additional capacity for transfers. Crop idling in the Export Service Area would occur most during wet years or when stored/banked groundwater would not be available; however, purchases would be more expensive in the Export Service Area. The Flexible Purchase Alternative would rely more heavily on the Export Service Area during wet years due to limited Delta pump capacity. Transfers in this area could involve up to 540,000 AF and progressively decrease during dry conditions. Crop idling decisions also depend upon precipitation in the northern and southern State; precipitation would affect export pump availability and how the State Water Project (SWP) allocates existing resources.

EWA agencies would like the ability to extend annual crop idling contracts. Contracts for multi-year water transfers would be made with water agencies. Consistent with the project description, multi-year contracts would not result in idling more than 20 percent of available rice or cotton acreage in a county or region. These stipulations would maintain the current economic and social conditions.

Described below are the maximum effects on farm labor employment, if the EWA agencies acquire the maximum amount of water from crop idling. Exceeding historic unemployment levels could affect community stability. The basis for a worst-case scenario analysis is to identify all potential effects. Crop idling affecting fewer laborers than historic fluctuations under this alternative would affect even less with decreased crop idling.

12.2.3.1 Upstream from the Delta

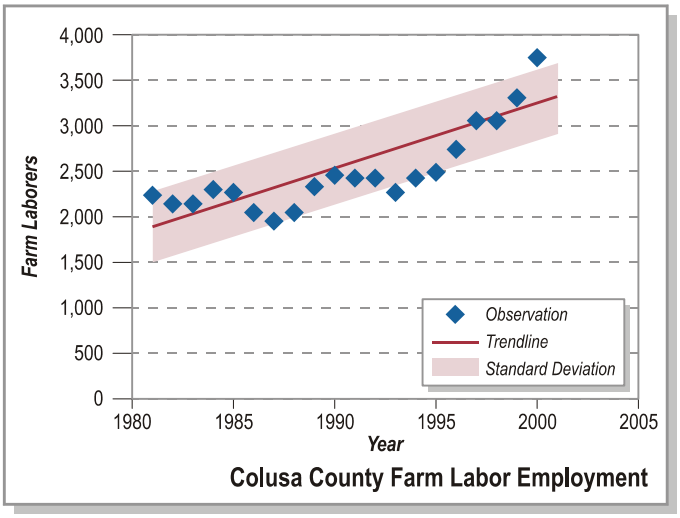
Table 12-4 shows the maximum acreage that could be idled in each county under 1995 through 1999 economic conditions, according to the 20 percent measure incorporated into the project description. (See Section 11.2.3 for further discussion on the 20 percent crop idling measure.) Consistent with 1999 University of California Cooperative Extension Crop Budgets, 2.7 workers are required for every 1,000 acres of rice. The following analysis identifies the number of full-time farm workers that would be displaced by maximum crop idling in each county.

Table 12-4
Maximum Proposed Acreages for Rice Idling for Flexible Purchase Alternative

	Total Acres of Rice in County[(1)]	***Maximum Acreage Proposed for Idling in Dry Years***	***% of Total***
Butte	95,120	19,000	20.0%
Colusa	132,338	26,460	20.0%
Glenn	83,777	16,750	20.0%
Placer	16,379	3,280	20.0%
Sutter	96,722	19,340	20.0%
Yolo	23,822	4,770	20.0%
Total	448,158	89,600	20.0%

(1) The figures representing total rice acres within the counties are based on a five-year average to take into account any recent land trends in rice production. The data is taken from the County Agricultural Commissioners Reports from 1995 to 1999.

12.2.3.1.1 Butte County



EWA acquisition of water through crop idling in Butte County would decrease farmworker employment. Idling 19,000 acres would displace 51 full-time laborer equivalents.

Analysis of data reveals Butte County is experiencing an increase in farm labor employment with annual seasonal and economic variations (standard deviation of the trend) of 170 laborers (Figure 12-3). EWA crop idling in Butte County would, however, affect fewer laborers than historic fluctuations.

REIS 2002

Figure 12-3
Butte County Farm Labor Trends

REIS 2002

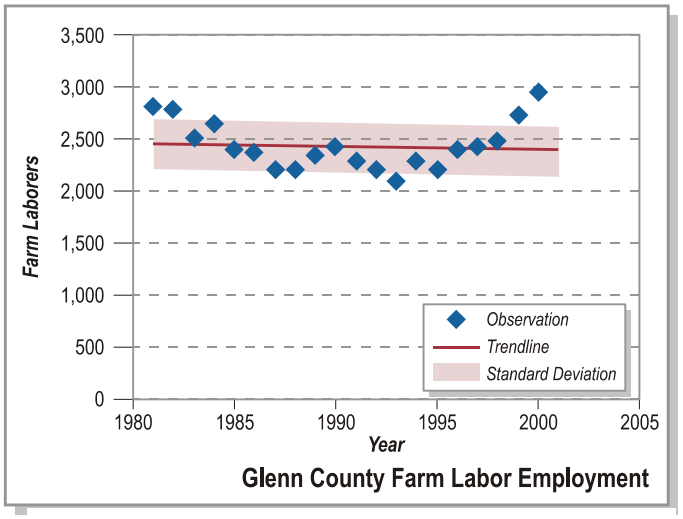


Figure 12-4
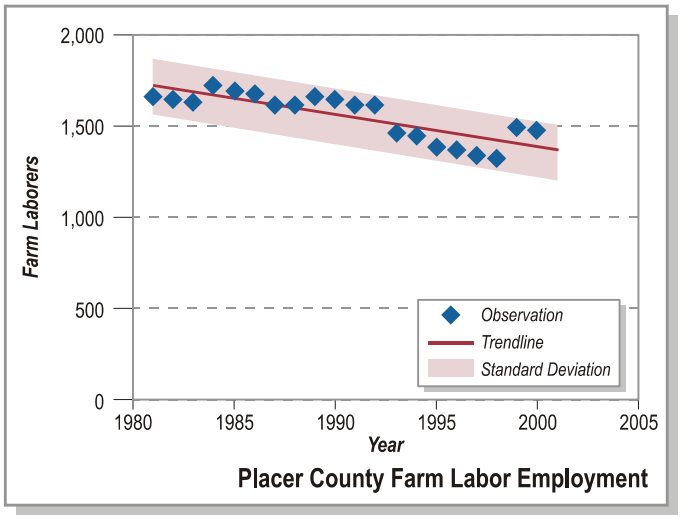
Colusa County Farm Labor Trends

12.2.3.1.2 Colusa County

EWA acquisition of water through crop idling in Colusa County would decrease farmworker employment. Idling 26,460 acres would displace 71 full-time laborer equivalents. Analysis of employment data reveals Colusa County is experiencing increasing levels of farm labor employment (Figure 12-4). Seasonal and economic changes in the Baseline Condition result in fluctuations (standard deviation on the trend) of 382 laborers. Crop idling in Colusa County would affect fewer laborers than historic fluctuations.

12.2.3.1.3 Glenn County



EWA acquisition of water through crop idling in Glenn County would decrease farmworker employment. Idling 16,750 acres would displace 45 full-time laborer equivalents (the equivalent of 45 full-time workers for 1 year). Analysis of employment data reveals no increasing or decreasing farm labor trends in Glenn County over the past 20 years, as shown

REIS 2002

Figure 12-5
Glenn County Farm Labor Trends

on Figure 12-5. Seasonal and economic changes in the Baseline Condition result in fluctuations (standard deviation of the average) of 237 laborers relative to the average number of employed farm laborers. Crop idling would affect farm laborers less than historic fluctuations.

REIS 2002

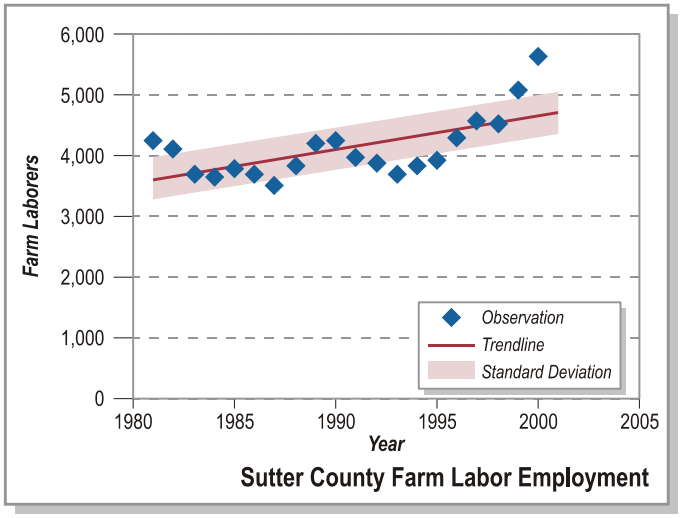


Figure 12-6
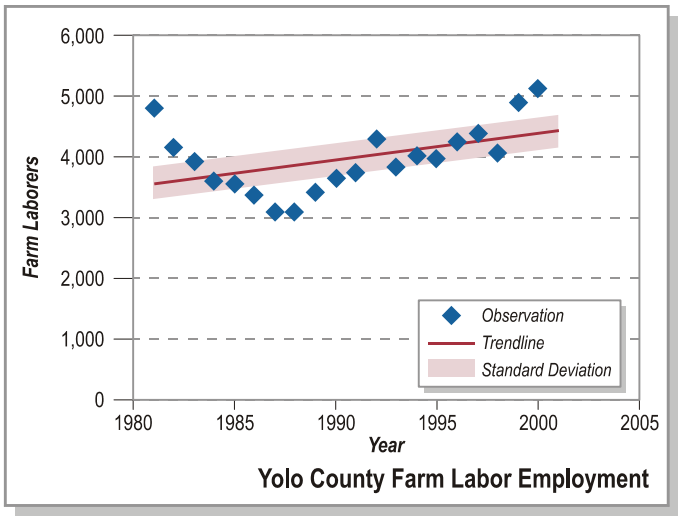
Placer County Farm Labor Trends

12.2.3.1.4 Placer County

EWA acquisition of water through crop idling in Placer County would decrease farmworker employment. Idling 3,280 acres would displace 9 full-time laborer equivalents. Analysis of 20 years of farm labor employment information reveals Placer County is experiencing decreasing farm labor employment with annual seasonal fluctuations (standard deviation of the trend) of 106 laborers (Figure 12-6). Crop idling in Placer County would affect fewer laborers than historic fluctuations.

12.2.3.1.5 Sutter County

EWA acquisition of water through crop idling in Sutter County would decrease farmworker employment. Idling 19,340 acres would displace 52 full-time laborer equivalents. Analysis of data reveals Sutter County is experiencing an increase in farm labor employment with annual seasonal and economic baseline variations (standard deviation of the trend) of 337 laborers (Figure 12-7). Crop idling in Sutter County would affect fewer laborers than historic fluctuations.



REIS 2002

Figure 12-7
Sutter County Farm Labor Trends

12.2.3.1.6 Yolo County

EWA acquisition of water through crop idling in Yolo County would decrease farmworker employment. Idling 4,770 acres would displace 13 full-time laborer equivalents. Analysis of data reveals Yolo County is experiencing increases in farm labor employment with annual seasonal and economic changes that result in variations of (standard deviations on the trend) 257 laborers (Figure 12-8). Crop idling in Yolo County would affect fewer laborers than historic fluctuations.

REIS 2002

Figure 12-8
Yolo County Farm Labor Trends

12.2.3.2 Export Service Area

Crop idling in the Export Service Area would occur in Kings, Tulare, Kern, and western Fresno Counties. Table 12-5 provides the maximum number of acres of cotton that is proposed for idling in these counties under 1995 through 1999 economic conditions. Refer to Chapter 11, Regional and Agricultural Economics, for further discussion on the development of these acreages. Consistent with 1999 University of California Cooperative Extension Crop Budgets, a weighted average of 6.6 full time job equivalents is required for every 1000 acres of cotton.

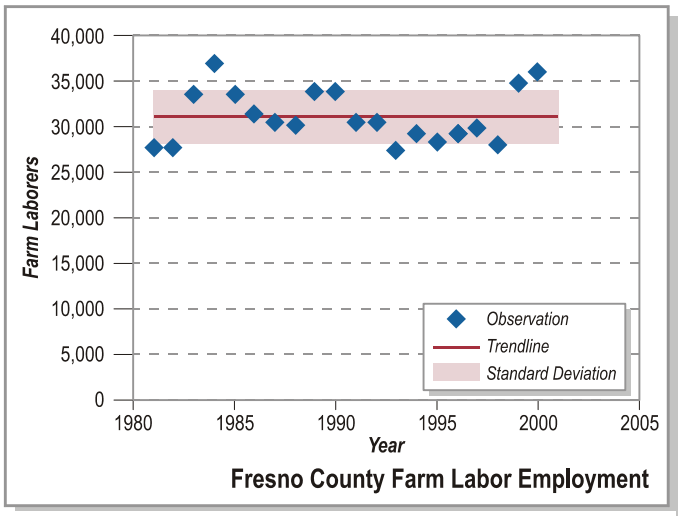


Table 12-5
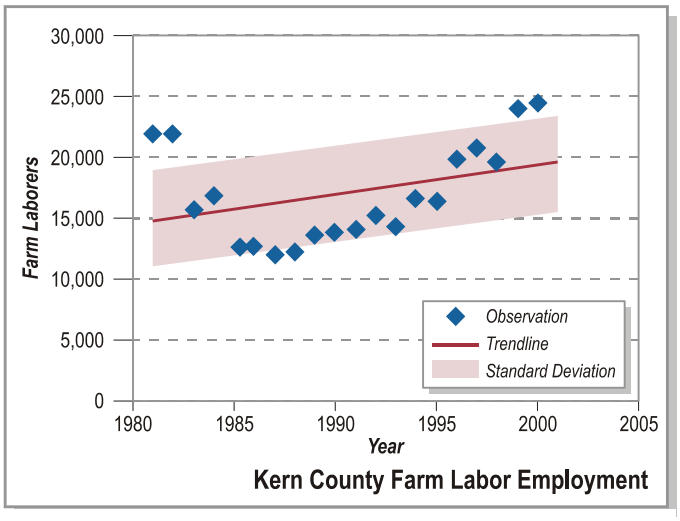
Maximum Proposed Acreages for Cotton Idling for Flexible Purchase Alternative

	Total Acres of Cotton in County[1]	***Maximum Acreage Proposed for Idling in Dry Years***	***% of Total***
Fresno	352,880	70,500	20.0%
Kern	246,616	49,300	20.0%
Kings	222,543	44,500	20.0%
Tulare	92,680	18,500	20.0%

[1] The figures representing total cotton acres within the counties are based on a five-year average to take into account any recent land trends in rice production. The data is taken from the County Agricultural Commissioners Reports from 1995 to 1999.



12.2.3.2.1 *Fresno County*

EWA acquisition of water through crop idling in Fresno County would decrease farmworker employment. Idling 70,500 acres would displace 465 full-time laborer equivalents. Analysis of farm labor data reveals Fresno's farm labor employment is neither increasing nor decreasing (Figure 12-9). Baseline farm employment fluctuates annually by (standard deviation of the average) 2,933 laborers. Crop idling in Fresno County would affect fewer laborers than historic fluctuations.

REIS 2002

Figure 12-9
Fresno County Farm Labor Trends

REIS 2002

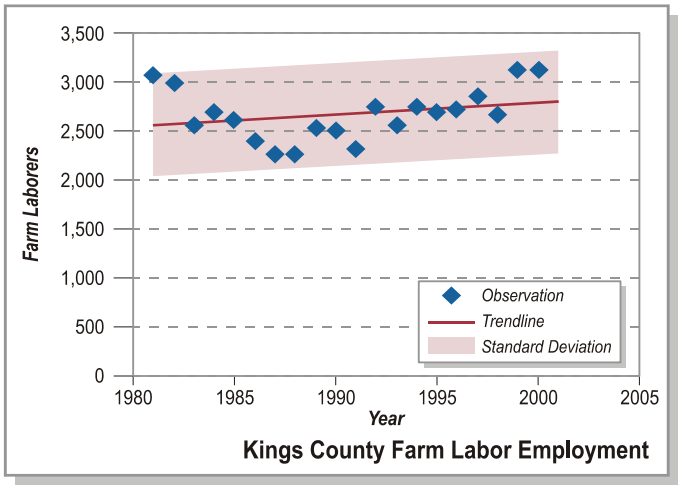


Figure 12-10
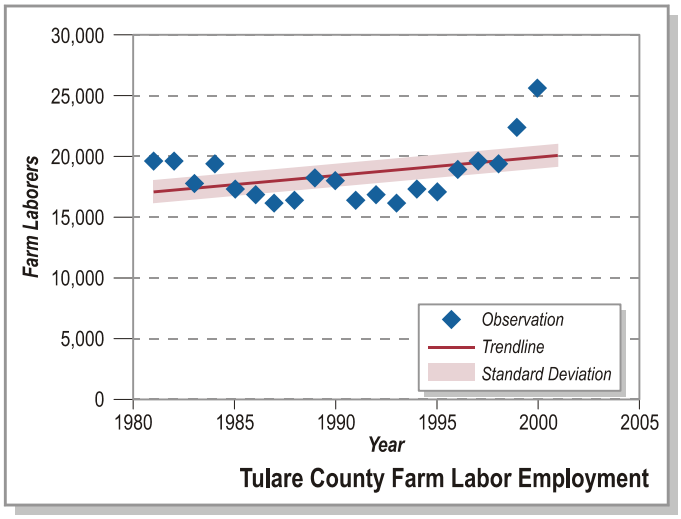
Kern County Farm Labor Employment

12.2.3.2.2 *Kern County*

EWA acquisition of water through crop idling in Kern County would decrease farmworker employment. Idling 49,300 acres would displace 325 full-time laborer equivalents. Analysis of farm labor data reveals increases in farm labor employment in Kern County (Figure 12-10). Baseline farm employment fluctuates annually by (standard deviation of the trend) 1,445 laborers. Crop idling in Kern County would affect fewer laborers than historic fluctuations.

12.2.3.2.3 *Kings County*



EWA acquisition of water through crop idling in Kings County would decrease farmworker employment. Idling 44,500 acres would displace 294 full-time laborer equivalents. Analysis of farm labor data reveals farm labor employment in Kings County is neither increasing nor decreasing (Figure 12-11). Baseline farm employment fluctuates annually by 530 laborers (standard deviation of the

REIS 2002

Figure 12-11
Kings County Farm Labor Trends

trend). Crop idling in Kings County would affect fewer laborers than historic fluctuations.

REIS 2002

Figure 12-12
Tulare County Farm Labor Trends

12.2.3.2.4 Tulare County

EWA acquisition of water through crop idling in Tulare County would decrease farmworker employment. Idling 18,500 acres would displace 122 full-time laborer equivalents. Analysis shows farm labor employment in Tulare County is increasing with seasonal variations of (standard deviation of trend) 922 laborers (Figure 12-12). Crop idling in Tulare County would affect fewer laborers than historic fluctuations.

EWA crop idling effects on farm labor do not exceed historic farm labor employment fluctuations in any county in the Upstream from the Delta Region or Export Service Area. Because crop idling does not exceed normal fluctuations induced by seasonal or economic changes, current components of community stability would not be disrupted by crop idling.

12.2.4 Environmental Consequences/Environmental Impacts of Fixed Purchase Alternative

The Fixed Purchase Alternative specifies purchases of 35,000 acre-feet in the Upstream from the Delta Region, and 150,000 acre-feet in the Export Service Area. While the amounts in each region are fixed, the acquisition types and sources could vary. To allow the EWA Project Agencies maximum flexibility when negotiating purchases with willing sellers, this section analyzes the effect of maximum crop idling in all regions in the same year. In all instances, water transfer requirements for the Fixed Purchase Alternative impose correspondingly fewer effects on labor in Butte, Colusa, Glenn, Sutter, and Fresno Counties. In Placer, Yolo, Kern, Kings, and Tulare counties, the effects remain the same (Table 12-6).

EWA agencies would like the ability to extend annual crop idling contracts for the Fixed Purchase Alternative. Consistent with the project description, multi-year contracts would not result in idling more than 20 percent of available rice or cotton acreage in a county or region. These stipulations would maintain the current economic and social conditions.

Table 12-6 describes proposed acreages for rice and cotton idling under the Fixed Alternative; effects are all less than normal historic fluctuations. Future projects that

would occur during No Project conditions would add to loss of farm laborer jobs, particularly in Fresno and Kings counties. (See Chapter 22, Cumulative Effects.)

Table 12-6
Proposed Acreage for Rice Idling for Fixed Purchase Alternative

Region	*County*	*Total Acres of Rice/ Cotton in County*[1]	*Maximum Acreage Proposed for Idling in Dry Years*	*Percent of Total Rice/ Cotton Acres to be Idled*	*Maximum Number of Jobs Lost*
Upstream from the Delta Region	Butte	95,120	10,600	11.1%	29
	Colusa	132,338	15,000	11.3%	41
	Glenn	83,777	15,000	17.9%	41
	Placer	16,379	3,280	20.0%	9
	Sutter	96,722	10,600	10.9%	29
	Yolo	23,822	4,770	20.0%	13
Export Service Area	Fresno	352,880	65,000	18.4%	429
	Kern	246,616	49,300	20.0%	325
	Kings	222,543	44,500	20.0%	294
	Tulare	92,680	18,500	20.0%	122

(1) The figures representing total acres within the counties are based on a five-year average to take into account any recent land trends. The data is taken from the County Agricultural Commissioners Reports from 1995 to 1999.

12.2.5 Comparative Analysis of Alternatives

12.2.5.1 Upstream from the Delta

The Flexible Purchase Alternative analyzed the effects of the "worst-case scenario" produced by idling the maximum allowable crop acreage in a single year. This approach ensures consideration of the full scope of maximum effects, while it provides the EWA Project Agencies flexibility when annually choosing acquisition options. Because of the variety of acquisition options, EWA Project Agencies would not rely solely on crop idling for maximum water purchases. This section provides information about how EWA would more likely operate in different year types.

Under the No Action/No Project Alternative, farm labor is generally increasing in the Upstream from the Delta counties of Colusa, Yolo, Butte, and Sutter. Urbanization in Placer County is resulting in a declining trend in farm labor employment levels. These trends are expected to continue during wet and dry years under No Action/No Project conditions.

In the Upstream from the Delta Region, the Fixed Purchase Alternative would be limited to a maximum acquisition of 35,000 acre-feet from all sources of water. In most years, this amount could be obtained from stored reservoir water purchases. In those years when surface water assets were not available (in part or in total), the EWA agencies would acquire water first from groundwater substitution and/or groundwater purchase, followed by crop idling. Because of other readily available water acquisition options in the Upstream from the Delta Region, it is unlikely that crop idling would take place under the Fixed Purchase Alternative.

The Flexible Purchase Alternative could involve the purchase of up to 600,000 acre-feet of water from all sources upstream from the Delta during dry years. EWA

agencies would prefer to purchase water from upstream sources because the water is generally less expensive. The amount that could be purchased would be limited by the excess capacity of the Delta export pumps to move the water to export areas south of the Delta. During wet years, excess pump capacity may be limited to as little as 50,000 acre-feet of EWA asset water because the pumps primarily would be used to export State and Federal Project water to Export Service Area users. During dry years, when there would be less Project water available for pumping (and therefore the pumps would have greater availability capacity), the EWA Project Agencies could acquire up to 600,000 acre-feet of water from all sources upstream from the Delta that could result in maximum crop idling.

The potential for agricultural social effects during wet years for the Flexible Purchase Alternative would be very similar to the Fixed Purchase Alternative. That is, during wet years, acquisitions would most likely be from stored water sources, and crop idling would not be exercised. However, as rainfall amounts for areas north of the Delta decrease, reflecting dry year conditions, the greater Delta export capacity could result in a heavier reliance on crop idling for EWA acquisitions. If the EWA Project Agencies were to acquire 600,000 acre-feet in the Upstream from the Delta Region, they would need to utilize the most available sources, which would include stored reservoir water, groundwater substitution, groundwater purchase, and crop idling. Crop idling in dry years would reflect the socioeconomic conditions described above produced by maximum crop idling.

12.2.5.2 Export Service Area

Under the No Action/No Project Alternative, farm labor is generally increasing in the Export Service Area counties of Fresno, Kern, and Tulare Counties, yet remains stable in Kings County. These trends are expected to continue during wet and dry years under No Action/No Project conditions.

EWA asset acquisitions in the Export Service Area under the Fixed Purchase Alternative would be limited to 150,000 acre-feet from stored groundwater and crop idling sources. The EWA agencies would purchase stored groundwater first, and then purchase water from crop idling if more is needed. Stored groundwater has finite availability, and 150,000 acre-feet would not likely be available in all years. In years with less stored groundwater availability, EWA agencies would turn to crop idling for the remaining water.

EWA asset acquisitions in the Export Service Area under the Flexible Purchase Alternative would be dependent on the water year type north of the Delta. Export pump capacity during wet years would limit the ability of the EWA Project Agencies to move assets through the Delta, increasing their reliance on purchases from Export Service Area sources. During wet years, acquisitions within the Export Service Area could involve up to 600,000 acre-feet of assets. Much of this water would be from crop idling; therefore, socioeconomic effects of the Flexible Purchase Alternative are likely to be greater than the Fixed Purchase Alternative.

Both the Fixed Purchase Alternative and Flexible Purchase Alternative would increase the water supply reliability from the Baseline Condition in the Export Service Area. Increased water supply reliability could result in a reduction of idled crops in dry years and increased crop idling during wet years (due to diminished Delta capacity). Extremes in farm labor employment levels could slightly diminish as a result of increasing the water supply reliability during dry years and increased crop idling during wet years.

Table 12-7 compares the percentages of the maximum number of jobs lost under the Fixed and Flexible Purchase Alternative crop idling scenarios. Job losses reflect maximum idling conditions in each county. The number of jobs affected under the Fixed Purchase Alternative is equal to or less than those produced by the Flexible Purchase Alternative. Table 12-8 compares the number of acres proposed for idling in each county and the number of jobs affected for each alternative.

EWA water acquisition effects on farm labor do not exceed historic farm labor employment fluctuations. Currently established unemployment programs within the State and county include, but are not limited to, MediCal, CalWORKS, food stamps, and regional occupational training programs that provide services for displaced workers. These established programs address individually displaced farmworkers' needs and serve to buffer most, but not all, of the direct effects of economic, seasonal, and hydrologic changes that contribute to changing employment levels. Services that cover medical insurance and living expenses are lacking.

Table 12-7
Maximum Number of Jobs Lost to Crop Idling Under Fixed Purchase and Flexible Purchase Alternative

Region	*County*	*Total Farm Employment*[1]	*Maximum Number of Farmworker Jobs Lost by Fixed Purchase Alternative*	*Percent of Total Farm Employment Affected Under Fixed Purchase Alternative*	*Maximum Number of Farmworker Jobs Lost by Flexible Purchase Alternative*	*Percent of Total Farm Employment Affected Under Flexible Purchase Alternative*
Upstream from the Delta Region	Butte	3,496	28	0.8%	51	1.5%
	Colusa	2,633	41	1.6%	71	2.7%
	Glenn	2,062	41	2.0%	45	2.2%
	Placer	1,032	9	0.9%	9	0.9%
	Sutter	3,937	29	0.7%	52	1.3%
	Yolo	3,576	13	0.4%	13	0.4%
	Total	16,736	161	1.0%	241	1.4%
Export Service Area	Fresno	25,161	429	1.7%	465	1.8%
	Kern	17,126	325	1.9%	325	1.9%
	Kings	4,361	294	6.7%	294	6.7%
	Tulare	17,982	122	0.7%	122	0.7%
	Total	64,630	1170	1.8%	1206	1.9%

(1) 1999 REIS county farm employment includes hired workers that include bookkeepers, secretaries, and mechanics. Philip Martin, Ph.D., UCD, nationally recognized local expert on farm labor issues, states as a general "rule of thumb" that 25-40 percent of people reported by agricultural employers do not work directly on the farm. Therefore, the farmworker column represents 70 percent of REIS farm employment.

Table 12-8
Comparison of Maximum Effects for Flexible and Fixed Purchase Alternatives on Agricultural Social Issues

Region		Asset Acquisition or Management	Result	Impacts	Flexible Alternative Change	Fixed Alternative Change
Upstream from the Delta Region	Butte	Crop Idling	Temporary conversion of rice crops to bare fields	Reduce rice crop acreage in Butte County	Idle 19,000 acres of rice resulting in 51 lost farm laborer jobs	Idle 10,600 acres resulting in 29 lost farm laborer jobs
	Colusa	Crop Idling	Temporary conversion of rice crops to bare fields	Reduce rice crop acreage in Colusa County	Idle 26,460 acres of rice resulting in 71 lost farm laborer jobs	Idle 15,000 acres of rice resulting in 41 lost farm laborer jobs
	Glenn	Crop Idling	Temporary conversion of rice crops to bare fields	Reduce rice crop acreage in Glenn County	Idle 16,750 acres of rice resulting in 45 lost farm laborer jobs	Idle 15,000 acres of rice resulting in 41 lost farm laborer jobs
	Placer	Crop Idling	Temporary conversion of rice crops to bare fields	Reduce rice crop acreage in Placer County	Idle 3,280 acres of rice resulting in 9 lost farm laborer jobs	Idle 3,280 acres of rice resulting in 9 lost farm laborer jobs
	Sutter	Crop Idling	Temporary conversion of rice crops to bare fields	Reduce rice crop acreage in Sutter County	Idle 19,340 acres of rice resulting in 52 lost farm laborer jobs	Idle 10,600 acres resulting in 29 lost farm laborer jobs
	Yolo	Crop Idling	Temporary conversion of rice crops to bare fields	Reduce rice crop acreage in Yolo County	Idle 4,770 acres of rice resulting in 13 lost farm laborer jobs	Idle 4,770 acres of rice resulting in 13 lost farm laborer jobs
Export Service Area	Fresno	Crop Idling	Temporary conversion of cotton crops to bare fields	Reduce cotton crop acreage in Fresno County	Idle 70,500 acres of cotton resulting in 465 lost farm laborer jobs	Idle 65,000 acres of cotton resulting in 429 lost farm laborer jobs
	Kern	Crop Idling	Temporary conversion of cotton crops to bare fields	Reduce cotton crop acreage in Kern County	Idle 49,300 acres of cotton resulting in 325 lost farm laborer jobs	Idle 49,300 acres of cotton resulting in 325 lost farm laborers
	Kings	Crop Idling	Temporary conversion of cotton crops to bare fields	Reduce cotton crop acreage in Kings County	Idle 44,500 acres of cotton resulting in 294 lost farm laborer jobs	Idle 44,500 acres of cotton resulting in 294 lost farm laborer jobs
	Tulare	Crop Idling	Temporary conversion of cotton crops to bare fields	Reduce cotton crop acreage in Tulare County	Idle 18,500 acres of cotton resulting in 122 lost farm laborer jobs	Idle 18,500 acres of cotton resulting in 122 lost farm laborer jobs

12.2.6 Cumulative Effects

Water acquisition programs considered for cumulative analysis include: 1) Sacramento Valley Water Management Agreement, 2) Dry Year Purchase Program, 3) Drought Risk Reduction Investment Program (DRRIP), 4) Central Valley Project Improvement Act (CVPIA) Water Acquisition Program (WAP), 5) Environmental Water Program, and the 6) CALFED Ecosystem Restoration Program (ERP). Chapter 22 presents details on each of these programs. Potential effects of these programs are described below. Of additional consideration are future crop idling programs such as the Westland Global Land Settlement Program and programs that arise in response to a reduction of Colorado River water.

Of the above mentioned water acquisition programs, those that can be eliminated from further analysis are those that do not use crop idling and those that will combine into a single program. At this time the Sacramento Valley Water Management Agreement does not include water acquisition via crop idling and are subsequently eliminated from further agricultural social issue analysis. In October 2004, with completion of a programmatic document, the Dry Year Purchase Program will be combined into the DRRIP (Jones 2002). Though the full scope is yet undetermined, it is possible that water acquisition via crop idling in the Export Service Area is entirely possible (Jones 2002). The Dry Year Purchase Program and DRRIP will be analyzed as one crop-idling acquisition program.

Cumulative effects would apply to those water acquisition programs purchasing water via crop idling in the Upstream from the Delta Region during dry years and in the Export Service Area. Crop idling would most likely occur in the Upstream from the Delta Region during dry years because capacity through the Delta increases. The programs that would exercise similar options are the CVPIA WAP, the EWP, the ERP, and DRRIP. CVPIA (WAP) purchases water from willing sellers given sufficient quantities are available (Jewel 2002). Water transfers through the Delta for the CVPIA (WAP) and DRRIP generally take priority over EWA, which reduce the potential for EWA crop idling. CALFED agencies developed the EWP to carry out flow-related goals of the ERP. The EWP on behalf of the ERP could purchase agricultural land in the Upstream from the Delta Region for habitat restoration and reduce the demand for farm labor.

Careful attention should be given to future projects underway in Kings and Fresno Counties. Although details are still under negotiation and the final outcome is unclear, Westland Water District is planning to permanently idle up to 200,000 acres of drainage-impaired land. Once details of Westland's proposed Global Land Settlement Program become available, it is assumed that there will be a transition period requiring coordination between water acquisition programs and farm labor before crop idling can occur. EWA agencies would maintain close contact with these counties to identify potential effects.

EWA agencies would avoid cumulative effects to farmworkers subsequent to these programs by conducting annual investigations of crop idling conditions in each county and water district before initiating further crop idling discussion. During such investigations the EWA agencies would consider other reasonably, foreseeable transfers by all water transfer programs when determining where to acquire water through crop idling. EWA agencies would then only purchase water from idling 20 percent of the rice land in a county, where this 20 percent would include the other, reasonably foreseeable transfers. Information regarding the amount of idled crop acreage should come from DWR Land Use Surveys, the USDA, and county crop reports. Local Farm Bureaus, UCCE offices, Agricultural Commissioners Offices, or other crop specific authorities could verify the information. With careful coordination, data collection, and verification efforts, crop idling for the EWA would not cumulatively contribute adverse conditions on farm labor.

Chapter 13
Agricultural Land Use

Converting farmland into homes and other urban uses is a public issue in most agricultural regions experiencing rapid urbanization. California's multi-billion dollar agricultural industry depends on a large supply of fertile farmland for both crop and animal production. California's growing population necessitates further development of land, threatening open space and agricultural lands. This elevating conflict has led to the development of several state and federal programs aimed towards protecting farmland. Crop idling would be the only EWA action that would directly affect land use in California. Implementation of the EWA would not interfere with any of the existing land protection programs, nor would it permanently alter current land use plans in the area of analysis.

13.1 Affected Environment/Existing Conditions

EWA water acquisitions from crop idling could alter agricultural land use conditions. This section discusses numerous State and Federal programs designed to protect agricultural and open space land. This section also describes the existing land use conditions and presents data on recent land use conversions in the counties potentially affect by EWA crop idling actions. Counties selected for inclusion in the areas of potential idling contain extensive rice or cotton acreage and have irrigation districts that have indicated a willingness to participate in the EWA Program.

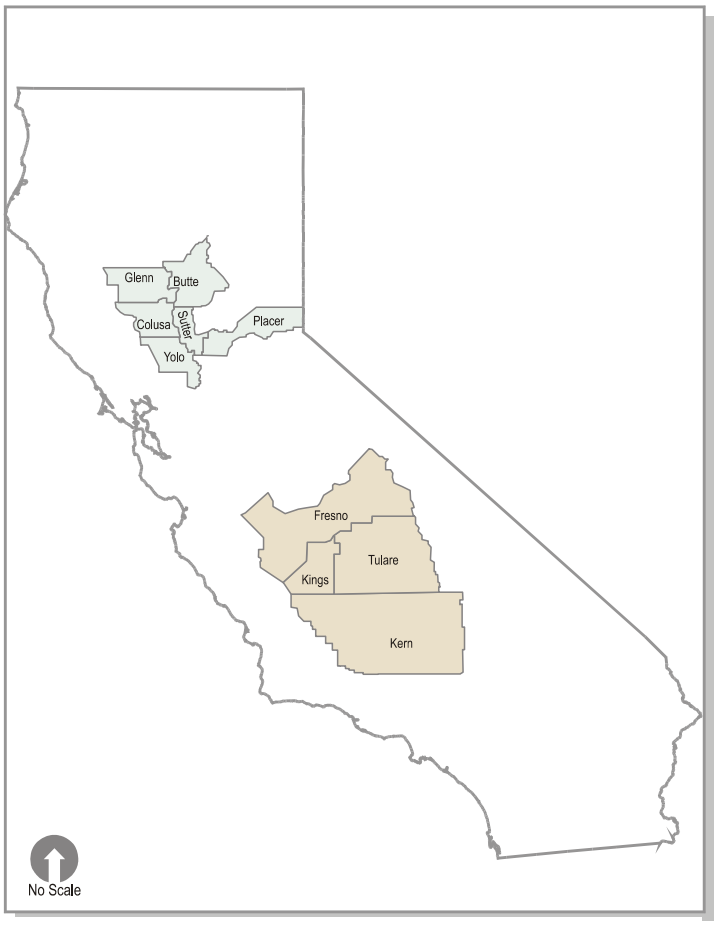

Figure 13-1
Agricultural Land Use Area of Analysis

13.1.1 Area of Analysis

This chapter divides California into two regions: the Upstream from the Delta Region and the Export Service Area. As noted above, the EWA agencies are considering rice idling in the upstream from the Delta counties of Butte, Colusa, Glenn, Placer, Yolo, and Sutter and cotton idling in the Export Service Area counties of Fresno, Kern, Kings, and Tulare. The boundaries of each county in each region define the Upstream from the Delta Region and the Export Service Area (Figure 13-1).

13.1.2 Land Resource Protection Programs

The following sections describe programs that exist to promote the preservation of open space and agricultural lands and wildlife habitat in the State.

13.1.2.1 Williamson Act

The California Land Conservation Act, better known as the Williamson Act, has been the State's premier agricultural land protection program since its enactment in 1965. The California Legislature passed the Williamson Act in 1965 to preserve agricultural and open space lands by discouraging premature and unnecessary conversion to urban uses. The act creates an arrangement whereby private landowners contract with counties and cities to voluntarily restrict their land to agricultural and compatible open space uses. The vehicle for these agreements is a rolling term, 10-year contract (unless either party files a "notice of nonrenewal," the contract is automatically renewed for an additional year). In return, restricted parcels are assessed for property tax purposes at a rate consistent with their actual use, rather then potential market value. The Williamson Act also establishes a Farmland Security Zone, which introduces a 20-year contract between a private landowner and a county that restricts land to agricultural or open space uses.[1]

Table 13-1 displays farm acreage by county enrolled in the Williamson Act and Farmland Security Zone program in 2001.

Table 13-1
2001 Williamson Act and Farmland Security Zone Enrolled Acreages

	Land Conservation Act		*Farmland Security Zone*				*Other Enforceable Restriction Enrollment*	
			Urban		*Non-Urban*			
County	*Prime*	*Nonprime*	*Prime*	*Nonprime*	*Prime*	*Nonprime*		*Total*
Butte	109,579	101,667	-	-	-	-	-	211,245
Colusa	77,329	195,684	5,730	323	23,387	1,189	-	303,642
Glenn	64,575	266,345	8,977	1,260	51,381	1,608	-	394,147
Placer	16,351	28,395	-	-	-	-	-	44,745
Sutter	6,802	-	-	-	-	-	-	6,802
Yolo	253,165	185,261	-	-	-	-	61	438,486
Fresno	1,080,671	487,075	-	-	1,386	-	-	1,569,133
Kern	823,687	810,965	13,014	-	72,197	-	-	1,719,863
Kings	336,796	119,201	28,194	227	210,444	3,750	-	698,612
Tulare	594,218	511,697	8,348	-	-	-	686	1,114,948

Source: Division of Land Resource Protection 2002

[1] A farmland security zone is essentially an area created within an agricultural preserve by a board of supervisors (board) upon request by a landowner or group of landowners. An agricultural preserve defines the boundary of an area within which a city or county will enter into Williamson Act contracts with landowners. The boundary is designated by resolution of the board or city council having jurisdiction. Agricultural preserves must generally be at least 100 acres in size.

13.1.2.2 California Farmland Conservancy Program

The State California Farmland Conservancy Program (CFCP) is a voluntary program that seeks to encourage the long-term, private stewardship of agricultural lands through the use of agricultural conservation easements. The CFCP provides grant funding for projects that use and support agricultural conservation easements for protection of agricultural lands. An agricultural conservation easement is a voluntary, legally recorded deed restriction that is placed on a specific property used for agricultural production. The goal of an agricultural conservation easement is to maintain agricultural land in active production by removing the development pressures from the land. Such an easement prohibits practices that would damage or interfere with the agricultural use of the land. Because the easement is a restriction on the deed of the property, the easement remains in effect even when the land changes ownership.

13.1.2.3 Conservation Reserve Program

The Conservation Reserve Program (CRP) is a Federal program administered by the Farm Services Agency. The CRP is a voluntary program that offers annual rental payments, incentive payments, and annual maintenance payments for certain activities, and cost-share assistance to establish approved cover on eligible cropland. To be eligible for placement in the CRP, land must be (1) cropland that is planted or considered planted to an agricultural commodity 2 of the 5 most recent crop years (including field margins) and that is physically and legally capable of being planted in a normal manner to an agricultural commodity or (2) marginal pastureland that is either enrolled in the Water Bank Program or suitable for use as a riparian buffer to be planted to trees.

13.1.2.4 Wetlands Reserve Program

The Wetlands Reserve Program (WRP) is a voluntary program offering landowners the opportunity to protect, restore, and enhance wetlands on their property. The USDA Natural Resources Conservation Service (NRCS) provides technical and financial support to help landowners with their wetland restoration. The NRCS goal is to achieve the greatest wetland functions and values, along with optimum wildlife habitat, on every acre enrolled in the program. This program offers landowners an opportunity to establish long-term conservation and wildlife practices and protection. In California, the WRP has focused on the restoration of a variety of wetland types throughout the state, including seasonal wetlands, semi-permanent marsh, vernal pools along the perimeter of the Central Valley, riparian corridors, and tidally influenced wetlands.

13.1.2.5 CALFED Ecosystem Restoration Program

The goal of the CALFED Ecosystem Restoration Program (ERP) is to improve and increase aquatic and terrestrial habitats and improve ecological functions in the Bay-Delta system to support sustainable populations of diverse and valuable plant and animal species. The premise of the program is to improve the ecosystem health to

reduce the conflict between environmental water use and other beneficial uses and allow more flexibility in water management decisions.

Actions of the ERP include restoring habitat in the Delta, San Pablo Bay, Suisun Marsh, and Yolo Bypass. The program is also intended to establish wildlife-friendly agricultural lands. Through these objectives, the ERP may result in agricultural land being taken out of production.

13.1.2.6 Farmland Mapping and Monitoring Program

The Farmland Mapping and Monitoring Program (FMMP) was established in 1982 and produces maps and statistical data used for analyzing effects on California's agricultural resources. The maps are updated every 2 years with the use of aerial photographs, a computer mapping system, public review, and field reconnaissance. The FMMP rates agricultural land according to soil quality and irrigation status and denotes the best quality land Prime Farmland. FMMP characterizes land use into the following categories:

- **Prime Farmland[2] –** Land with the best combination of physical and chemical features able to sustain long-term production of agricultural crops. This land has the soil quality, growing season, and moisture supply needed to produce sustained high yields. Land must have been used for production of irrigated crops at some time during the two update cycles prior to the mapping date.

- **Farmland of Statewide Importance –** Land similar to Prime Farmland that has a good combination of physical and chemical characteristics for the production of crops. This land has minor shortcomings, such as greater slopes or less ability to store soil moisture than Prime Farmland. Land must have been used for production of irrigated crops at some time during the two update cycles prior to the mapping date.

- **Unique Farmland –** Lesser quality soils used for the production of the state's leading agricultural crops. This land is usually irrigated, but may include non-irrigated orchards or vineyards as found in some climatic zones in California. Land must have been cropped at some time during the two update cycles prior to the mapping date.

- **Farmland of Local Importance –** Land of importance to the local agricultural economy as determined by each county's board of supervisors and a local advisory committee.

- **Grazing Land –** Land on which the existing vegetation is suited to the grazing of livestock.

---

[2] The term 'Prime' as it refers to rating for agricultural uses has two meanings in California. FMMP determines the location and extent of 'Prime Farmland' as described above; while under the state's Williamson Act, land may be enrolled under the 'Prime Land' designation if it meets certain economic or production criteria. See Section 11.1.4 for specific definition.

- **Urban and Built-Up Land –** Land occupied by structures with a building density of at least one unit to 1.5 acres, or approximately six structures to one 10-acre parcel.

- **Other Land –** Land that does not meet the criteria of any other category.

- **Water –** Water areas with an extent of at least 40 acres.

Interim Farmland Mapping Categories[3]

- **Irrigated Farmland** - Cropped land with a developed irrigation water supply that is dependable and of adequate quality. Land must have been used for irrigated agricultural production at some time during the 4 years prior to the mapping date.

- **Nonirrigated Farmland** - Land on which agricultural commodities are produced on a continuing or cyclic basis using stored soil moisture.

13.1.3 Upstream from the Delta

The following data were taken directly from the Department of Conservation FMMP 2002. The data inventories acreages of land in each of the above land use categories in 1998 and 2000. Each county has an individual definition for the category Farmland of Local Importance that is set by the county's local advisory committee and adopted by the board of supervisors. Definitions are indicated below.

13.1.3.1 Butte County

In 2000, Butte County had a population of 203,100. Projections forecast that by the year 2020, Butte County's total population will reach 308,900 people (EDD 2002). Although agriculture remains a mainstay of Butte County's economy, farmland is increasingly being converted to urban uses and a significant amount of farmland is being restored to natural uses. In 2000, of the 917,909 acres mapped in Butte County, 522,297 acres were in agricultural use, 40,185 acres were urbanized, 21,643 acres were water and 333,784 acres were "other." (FMMP 2002) Table 13-2 summarizes further land use classifications and net changes in categories from 1998 to 2000. Land use data for Butte County are in the interim stages because recent soil survey information is unavailable. Table 13-3 specifies land use conversions from one category to another.

[3] For farmed areas lacking modern soil survey information and for which there is expressed local concern on the status of farmland, Irrigated and Nonirrigated Farmland substitute for the categories of important farmland Only Butte and Kern counties continue to have Interim Farmland data.

Table 13-2
Butte County Land Use Summary and Change by Land Use Category

			1998 to 2000 Acreage Changes			
	Total Acreage Inventoried		Acres Lost	Acres Gained	Total Acreage Changed	Net Acreage Changed
Land Use Category	1998	2000	(-)	(+)		
Irrigated Farmland	255,099	249,414	9,000	3,315	12,315	-5,685
Nonirrigated Farmland	9,372	7,901	1,664	193	1,857	-1,471
Interim Farmland Subtotal	264,471	257,315	10,664	3,508	14,172	-7,156
Grazing Land	264,778	264,982	3,090	3,294	6,384	204
Agricultural Land Subtotal	529,249	522,297	13,754	6,802	20,556	-6,952
Urban and Built-Up Land	39,243	40,185	1,147	2,089	3,236	942
Other Land	327,774	333,784	2,029	8,039	10,068	6,010
Water Area	21,643	21,643	0	0	0	0
Total Area Inventoried	917,909	917,909	16,930	16,930	33,860	0

Table 13-3
Land Use Conversion from 1998 to 2000, Butte County

From Land Use Category		To Irrigated Farmland	To Nonirrigated Farmland	Subtotal To Interim Farmland	To Grazing Land	Total Agricultural Land	To Urban and Built-Up Land	To Other Land	To Water Area	Total Converted to Another Use
Irrigated Farmland [1]	to:	--	157	157	1,940	2,097	817	6,086	0	9,000
Nonirrigated Farmland	to:	208	--	208	643	851	2	811	0	1,664
Interim Farmland Subtotal		208	157	365	2,583	2,948	819	6,897	0	10,664
Grazing Land [2]	to:	1,642	15	1,657	--	1,657	604	829	0	3,090
Agricultural Land Subtotal		1,850	172	2,022	2,583	4,605	1,423	7,726	0	13,754
Urban and Built-Up Land [3]	to:	407	6	413	421	834	--	313	0	1,147
Other Land [2]	to:	1,058	15	1,073	290	1,363	666	--	0	2,029
Water Area	to:	0	0	0	0	0	0	0	--	0
Total Acreage Converted	to:	3,315	193	3,508	3,294	6,802	2,089	8,039	0	16,930

(1) Conversion to Grazing Land and Other Land due to land left idle for three or more update cycles, newly identified ranchettes throughout the county, and expansion of the Llano Seco Rancho, Sacramento River and Upper Butte Basin Wildlife Areas.
(2) Conversion to Irrigated Farmland due to new orchards, rice fields, and irrigated pasture primarily in the western portion of the county.
(3) Conversions from Urban and Built-Up Land are primarily the result of refinements made to the urban boundary.

13.1.3.2 Colusa County

In 2000, Colusa County had a population of 18,800. Projections forecast that by the year 2020, Colusa County's total population will reach 39,200 (EDD 2002). In 2000, of the 740,392 acres mapped in Colusa County, 573,420 were in agricultural use, 4,257 acres were urbanized, 1,838 acres were water and 160,877 acres were "other." (FMMP 2002) Table 13-4 summarizes further land use classifications and net changes in land use categories. In Colusa County, Farmland of Local Importance includes all farmable lands with the county that do not meet the definitions of Prime, Statewide, or Unique, but are currently irrigated pasture or nonirrigated crops. The classification also includes nonirrigated land with soils qualifying for Prime farmland or Farmland of Statewide Importance and lands that would have Prime or Statewide designation and

have been improved for irrigation but are now idle. Table 13-5 specifies land use conversions from one category to another.

Table 13-4
Colusa County Land Use Summary and Change by Land Use Category

			1998 to 2000 Acreage Changes			
	Total Acreage Inventoried		Acres Lost	Acres Gained	Total Acreage Changed	Net Acreage Changed
Land Use Category	1998	2000	(-)	(+)		
Prime Farmland	201,910	202,232	2,116	2,438	4,554	322
Farmland of Statewide Importance	1,746	1,811	30	95	125	65
Unique Farmland	125,083	125,497	2,861	3,275	6,136	414
Farmland of Local Importance	239,966	236,354	4,318	706	5,024	-3,612
Important Farmland Subtotal	568,705	565,894	9,325	6,514	15,839	-2,811
Grazing Land	7,684	7,526	164	6	170	-158
Agricultural Land Subtotal	576,389	573,420	9,489	6,520	16,009	-2,969
Urban and Built-Up Land	4,293	4,257	433	397	830	-36
Other Land	157,872	160,877	1,772	4,777	6,549	3,005
Water Area	1,838	1,838	0	0	0	0
Total Area Inventoried [1]	740,392	740,392	11,694	11,694	23,388	0

[1] Total area inventoried represents information for the new Colusa County soil survey area. Prior reports classified farmland use in Colusa County with the Interim mapping categories of Irrigated and Nonirrigated.

Table 13-5
Land Use Conversion from 1998 to 2000, Colusa County

From Land Use Category		To Prime Farmland	To Farmland of Statewide Importance	To Unique Farmland	To Farmland of Local Importance	Subtotal Important Farmland	To Grazing Land	Total Agricultural Land	To Urban and Built-Up Land	To Other Land	To Water Area	Total Converted to Another Use
Prime Farmland [1]	to:	--	0	3	507	510	0	510	229	1,377	0	2,116
Farmland of Statewide Importance	to:	0	--	0	28	28	0	28	0	2	0	30
Unique Farmland [1]	to:	3	0	--	110	113	6	119	30	2,712	0	2,861
Farmland of Local Importance [2]	to:	1,816	95	2,032	--	3,943	0	3,943	57	318	0	4,318
Important Farmland Subtotal		1,819	95	2,035	645	4,594	6	4,600	316	4,409	0	9,325
Grazing Land	to:	0	0	5	0	5	--	5	28	131	0	164
Agricultural Land Subtotal		1,819	95	2,040	645	4,599	6	4,605	344	4,540	0	9,489
Urban and Built-Up Land [3]	to:	148	0	26	22	196	0	196	--	237	0	433
Other Land [2]	to:	471	0	1,209	39	1,719	0	1,719	53	--	0	1,772
Water Area	to:	0	0	0	0	0	0	0	0	0	--	0
Total Acreage Converted	to:	2,438	95	3,275	706	6,514	6	6,520	397	4,777	0	11,694

[1] Conversion to Other Land primarily due to boundary adjustments and identification of areas of native vegetation and wetlands throughout the County.
[2] Conversion to Prime Farmland and Unique Farmland due to new irrigated agriculture, primarily orchards, in the central portion of the county.
[3] Conversions from Urban and Built-Up Land primarily the result of refinements made to the urban boundary.

13.1.3.3 Glenn County

In 2000, Glenn County had a population of 26,400. Projections forecast that by the year 2020 Glenn County's total population will reach 46,500 people (EDD 2002). In 2000, of the 849,127 acres mapped in Glenn County, 583,974 were in agricultural use, 5,609

acres were urbanized, 5,759 acres were water, and 253,678 acres were "other." (FMMP 2002) Table 13-6 summarizes further land use classifications and net changes from 1998 to 2000. In Glenn County, Farmland of Local Importance includes all lands not qualifying for Prime, Statewide, or Unique farmland that are cropped on a continuing or cyclic basis (irrigation is not a consideration). The classification also includes all cropable land within the Glenn County water district boundaries not qualifying for the Prime, Statewide, or Unique designations. Table 13-7 specifies land use conversions from one category to another.

Table 13-6
Glenn County Land Use Summary and Change by Land Use Category

			1998 to 2000 Acreage Changes			
	Total Acreage Inventoried		Acres Lost	Acres Gained	Total Acreage	Net Acreage
Land Use Category	1998	2000	(-)	(+)	Changed	Changed
Prime Farmland	168,217	166,549	3,217	1,549	4,766	-1,668
Farmland of Statewide Importance	88,648	87,784	1,489	625	2,114	-864
Unique Farmland	11,073	11,605	774	1,306	2,080	532
Farmland of Local Importance	140,078	141,965	2,475	4,362	6,837	1,887
Important Farmland Subtotal	408,016	407,903	7,955	7,842	15,797	-113
Grazing Land	176,296	176,071	264	39	303	-225
Agricultural Land Subtotal	584,312	583,974	8,219	7,881	16,100	-338
Urban and Built-Up Land	5,378	5,609	178	409	587	231
Other Land	253,678	253,785	611	718	1,329	107
Water Area	5,759	5,759	0	0	0	0
Total Area Inventoried [1]	849,127	849,127	9,008	9,008	18,016	0

[1] Refinements made to the Sacramento River boundary may result in different acreage totals for Water and adjacent land use categories than those in the 1996-98 report.

Table 13-7
Land Use Conversion from 1998 to 2000, Glenn County

From Land Use Category		To Prime Farm-land	To Farmland of Statewide Importance	To Unique Farm-land	To Farm-land of Local Importance	Subtotal Important Farmland	To Grazing Land	Total Agricul-tural Land	To Urban and Built-Up Land	T0 Other Land	To Water Area	Total Converted to Another Use
Prime Farmland [1] [2]	to:	--	23	193	2,459	2,675	6	2,681	137	399	0	3,217
Farmland of Statewide Importance	to:	16	--	18	1,215	1,249	0	1,249	21	219	0	1,489
Unique Farmland [1] [2]	to:	100	16	--	590	706	10	716	24	34	0	774
Farmland of Local Importance	to:	931	452	871	--	2,254	23	2,277	178	20	0	2,475
Important Farmland Subtotal		1,047	491	1,082	4,264	6,884	39	6,923	360	672	0	7,955
Grazing Land	to:	22	17	167	37	243	--	243	0	21	0	264
Agricultural Land Subtotal		1,069	508	1,249	4,301	7,127	39	7,166	360	693	0	8,219
Urban and Built-Up Land [3]	to:	98	24	21	10	153	0	153	--	25	0	178
Other Land	to:	382	93	36	51	562	0	562	49	--	0	611
Water Area	to:	0	0	0	0	0	0	0	0	0	--	0
Total Acreage Converted	to:	1,549	625	1,306	4,362	7,842	39	7,881	409	718	0	9,008

[1] Conversions between Important Farmland categories primarily due to corrections made to soil unit identification throughout the county.
[2] Conversion to Farmland of Local Importance primarily due to land left idle for three update cycles.
[3] Conversion from Urban and Built-Up Land primarily due to refinements made to the urban boundary.

13.1.3.4 Placer County

In 2000, Placer County had a population of 248,400. Projections forecast that by the year 2020, Placer County's total population will reach 406,900 (EDD 2002). Since the FMMP began tracking changes in 1984, there has been a 78 percent increase in urbanized land in Placer County, as more than 18,000 acres of farmland and grazing land have been converted. The acceleration of growth in western Placer has placed the county among the top 10 urbanizing counties statewide in terms of acreage developed since 1994 (DOC 2002). In 2000, of the 411,531 acres mapped in Placer County, 180,342 were in agricultural use, 41,448 acres were urbanized, 5,026 acres were water and 184,585 acres were "other." (FMMP 2002) Table 13-8 summarizes further land use classifications and net changes in land use conversions from 1998 to 2000. In Placer County, Farmland of Local Importance is defined as farmlands not covered by the categories of Prime, Statewide or Unique. Farmland of Local Importance include lands zoned for agriculture by County Ordinance and the California Williamson Act, as well as dry farmed lands, irrigated pasture lands, and other agricultural lands of significant economic importance to the county. Lands that have the potential for irrigation from Placer County water supplies are also included in the Farmland of Local Importance designation. Table 13-9 specifies land use conversions from one category to another.

Table 13-8
Placer County Land Use Summary and Change by Land Use Category

			1998 to 2000 Acreage Changes			
	Total Acreage Inventoried		Acres Lost	Acres Gained	Total Acreage	Net Acreage
Land Use Category	1998	2000	(-)	(+)	Changed	Changed
Prime Farmland	9,750	9,901	696	847	1,543	151
Farmland of Statewide Importance	5,195	5,312	769	886	1,655	117
Unique Farmland	22,727	23,616	1,679	2,568	4,247	889
Farmland of Local Importance	114,452	111,987	4,920	2,455	7,375	-2,465

Other Land	to:	112	221	229	443	1,005	358	1,363	1,765	--	35	3,163
Water Area [5]	to:	0	0	0	0	0	63	63	0	6	--	69
Total Acreage Converted	to:	847	886	2,568	2,455	6,756	1,957	8,713	6,473	2,691	48	17,925

[1] Conversions between Important Farmland categories primarily due to corrections made to soil unit identification throughout the county.
[2] Conversion to Farmland of Local Importance primarily due to land left idle for three update cycles and refinements to agricultural boundaries.
[3] Conversion to Unique Farmland primarily due to new irrigated agriculture and refinements to agricultural boundaries.
[4] Conversion from Urban and Built-Up Land primarily the result of refinements made to the urban boundary around Roseville, Rocklin and Lincoln.
[5] Conversion to Grazing Land primarily due to refinements made to North Fork Lake and Rock Creek Lake.

13.1.3.5 Sutter County

In 2000, Sutter County had a population of 78,900. Projections forecast that by the year 2020 Sutter County's total population will reach 115,600 people (EDD 2002). Since 1990, 9,333 acres of farmland have gone out of production in Sutter County, and 2,354 acres of new urban land have been created (DOC 2002). In 2000, of the 389,439 acres mapped in Sutter County, 352,187 were in agricultural use, 11,360 acres were urbanized, 1,848 acres were water, and 24,044 acres were "other." (FMMP 2002) Table 13-10 summarizes further land use classifications and net changes from 1998 to 2000. In Sutter County, the Board of Supervisors determined there would be no Farmland of Local Importance designation. Table 13-11 specifies land use conversions from one category to another.

Table 13-10
Sutter County Land Use Summary and Change by Land Use Category

			1998 to 2000 Acreage Changes			
	Total Acreage Inventoried		Acres Lost	Acres Gained	Total Acreage	Net Acreage
Land Use Category	1998	2000	(-)	(+)	Changed	Changed

Total Area Inventoried	389,439	389,439	10,484	10,484	20,968	0

Table 13-11
Land Use Conversion from 1998 to 2000, Sutter County

From Land Use Category		To Prime Farm-land	To Farmland of Statewide Importance	To Unique Farm-land	To Farm-land of Local Importance	Subtotal Important Farmland	To Grazing Land	Total Agricul-tural Land	To Urban and Built-Up Land	To Other Land	To Water Area	Total Converted to Another Use
Prime Farmland	to:	--	43	21	0	64	901	965	235	959	0	2,159
Farmland of Statewide Importance [1]	to:	39	--	6	0	45	1,707	1,752	312	892	0	2,956
Unique Farmland [2] [3]	to:	222	0	--	0	222	602	824	0	1,552	0	2,376
Farmland of Local Importance	to:	0	0	0	--	0	0	0	0	0	0	0
Important Farmland Subtotal		261	43	27	0	331	3,210	3,541	547	3,403	0	7,491
Grazing Land	to:	1,228	349	232	0	1,809	--	1,809	253	167	0	2,229
Agricultural Land Subtotal		1,489	392	259	0	2,140	3,210	5,350	800	3,570	0	9,720
Urban and Built-Up Land [4]	to:	56	50	0	0	106	111	217	--	9	0	226
Other Land	to:	143	130	96	0	369	51	420	118	--	0	538
Water Area	to:	0	0	0	0	0	0	0	0	0	--	0
Total Acreage Converted	to:	1,688	572	355	0	2,615	3,372	5,987	918	3,579	0	10,484

[1] Refinements made to the Feather River boundary may result in different acreage totals for Water and adjacent land use categories than those in the 1996-98 report.
[2] Conversion to Grazing Land primarily due to land left idle for three or more update cycles.
[3] Conversions between Prime Farmland and Unique Farmland primarily due to corrections made to soil unit identification on the Yuba City quadrangle.
[4] Conversion to Other Land primarily due to wetland areas, ranchettes and agricultural processing facilities identified throughout the county.
[5] Conversion to Prime Farmland primarily due to new orchards, irrigated pasture, and alfalfa near the Sutter Buttes and in the southeastern portion of the county.
[6] Conversion from Urban and Built-Up Land primarily due to urban line corrections and newly identified orchards.

13.1.3.6 Yolo County

In 2000, Yolo County had a population of 168,660. Forecasts show that by the year 2020 Yolo County's total population will reach 236,400 (EDD 2002). Yolo County's agricultural land will continue to face development pressure in the foreseeable future. Since 1990, 22,253 acres of farmland have gone out of production in Yolo County and 3,513 acres of new urban land have been created (DOC 2002). In 2000, of the 653,451 acres mapped in Yolo County, 553,536 were in agricultural use, 25,939 acres were urbanized, 7,399 acres were water, and 66,577 acres were "other." (FMMP 2002) Table 13-12 summarizes further land use classifications and net increases and reductions in categories from 1998 to 2000. In Yolo County, Farmland of Local Importance includes cultivated farmland having soils which meet the criteria for Prime or Statewide, except that the land is not presently irrigated, and other nonirrigated land. Table 13-13 specifies land use conversions from one category to another.

Table 13-12
Yolo County Land Use Summary and Change by Land Use Category

			1998-00 Acreage Changes			
	Total Acreage Inventoried		Acres Lost	Acres Gained	Total Acreage Changed	Net Acreage Changed
Land Use Category	1998	2000	(-)	(+)		
Prime Farmland	265,915	264,452	2,467	1,004	3,471	-1,463
Farmland of Statewide Importance	18,202	18,072	351	221	572	-130
Unique Farmland	55,243	54,390	1,390	537	1,927	-853
Farmland of Local Importance	74,303	71,927	3,835	1,459	5,294	-2,376
Important Farmland Subtotal	413,663	408,841	8,043	3,221	11,264	-4,822
Grazing Land	143,385	144,695	763	2,073	2,836	1,310
Agricultural Land Subtotal	557,048	553,536	8,806	5,294	14,100	-3,512
Urban and Built-Up Land	25,586	25,939	381	734	1,115	353
Other Land	63,446	66,577	624	3,755	4,379	3,131
Water Area	7,371	7,399	2	30	32	28

Table 13-13
Land Use Conversion from 1998 to 2000, Yolo County

From Land Use Category		To Prime Farmland	To Farmland of Statewide Importance	To Unique Farmland	To Farmland of Local Importance	Subtotal Important Farmland	To Grazing Land	Total Agricultural Land	To Urban and Built-Up Land	To Other Land	To Water Area	Total Converted to Another Use
Prime Farmland	to:	--	0	5	918	923	215	1,138	425	904	0	2,467
Farmland of Statewide Importance	to:	11	--	0	161	172	7	179	51	121	0	351
Unique Farmland [1]	to:	60	8	--	108	176	865	1,041	0	349	0	1,390
Farmland of Local Importance [2]	to:	612	165	313	--	1,090	617	1,707	186	1,942	0	3,835
Important Farmland Subtotal		683	173	318	1,187	2,361	1,704	4,065	662	3,316	0	8,043
Grazing Land	to:	45	27	205	83	360	--	360	29	344	30	763
Agricultural Land Subtotal		728	200	523	1,270	2,721	1,704	4,425	691	3,660	30	8,806
Urban and Built-Up Land [3]	to:	93	8	4	121	226	60	286	--	95	0	381
Other Land	to:	183	13	10	68	274	307	581	43	--	0	624
Water Area	to:	0	0	0	0	0	2	2	0	0	--	2
Total Acreage Converted	to:	1,004	221	537	1,459	3,221	2,073	5,294	734	3,755	30	9,813

[1] Conversion to Prime Farmland primarily due to a correction made to soil unit identification on the Rumsey quadrangle.
[2] Conversion to Other Land due to lands left idle for four or more update cycles, primarily adjacent to the Sacramento River deep water channel.
[3] Conversions from Urban and Built-Up Land primarily the result of the ability to obtain a more distinct urban boundary.

13.1.4 Export Service Area

The following data are taken from the Department of Conservation FMMP 2002.

13.1.4.1 Fresno County

In 2000, Fresno County had a population of 799,400. Forecasts show that by the year 2020 Fresno County's total population will be over 1.1 million (EDD 2002). In 2000, of the 1,123,197 acres mapped in Fresno County, 961,858 were in agricultural use, 97,002 acres were urbanized, 3,891 acres were water and 60,446 acres were "other." (FMMP 2002) Table 13-14 summarizes further land use classifications and net changes in land use categories. In Fresno County, Farmland of Local Importance includes all farmable lands within the county that do not meet the definitions of Prime, Statewide, or Unique. This includes land that is or has been used for irrigated pasture, dry land farming, confined livestock and dairy, poultry facilities, aquaculture, and grazing land. Table 13-15 specifies land use conversions from one category to another.

Table 13-14
Fresno County Land Use Summary and Change by Land Use Category

			1998-00 Acreage Changes

Farmland of Statewide Importance [3]	to:	28	--	29	1,393	1,450	0	1,450	369	86	0	1,905
Unique Farmland [2] [3]	to:	14	143	--	1,112	1,269	3	1,272	429	38	0	1,739
Farmland of Local Importance [2]	to:	113	228	62	--	403	0	403	937	64	0	1,404
Important Farmland Subtotal		155	388	230	4,357	5,130	3	5,133	3,102	462	0	8,697
Grazing Land	to:	40	17	34	4	95	--	95	6	25	0	126
Agricultural Land Subtotal		195	405	264	4,361	5,225	3	5,228	3,108	487	0	8,823
Urban and Built-Up Land	to:	9	0	5	2	16	0	16	--	0	0	16
Other Land	to:	7	0	9	18	34	0	34	601	--	0	635
Water Area	to:	0	0	0	0	0	0	0	0	0	--	0
Total Acreage Converted	to:	211	405	278	4,381	5,275	3	5,278	3,709	487	0	9,474

(1) 1998 figures for Farmland of Local Importance, Other Land, and adjacent land use categories differ from those published in the 1996-98 report due to a revision of the Farmland of Local Importance definition to accommodate confined livestock and dairies, poultry facilities, and aquaculture.
(2) Conversions between Important Farmland categories primarily due to corrections made to soil unit identification throughout the county.
(3) Conversion to Farmland of Local Importance primarily due to land left idle for three or more update cycles, small feedlot expansions, and two newly identified fish farms.

13.1.4.2 Kern County

In 2000, Kern County had a population of 662,000. Forecasts show that by the year 2020, Kern County's total population will be almost 1.1 million (EDD 2002). Kern County's agricultural land will continue to face development pressure in the foreseeable future. In 2000, of the 2,550,619 acres mapped in Kern County, 1,595,146 were in agricultural use, 82,149 acres were urbanized, 973 acres were water, and 872,351 acres were "other." (FMMP 2002) Table 13-16 summarizes further land use classifications and net changes in land use categories. In Kern County, the Board of Supervisors determined that there would be no Farmland of Local Importance designation. Table 13-17 specifies land use conversions from one category to another.

Table 13-16
Kern County Land Use Summary and Change by Land Use Category

			1998 to 2000 Acreage Changes			
	Total Acreage Inventoried		Acres Lost	Acres Gained	Total Acreage	Net Acreage

Table 13-17
Land Use Conversion from 1998 to 2000, Kern County

From Land Use Category		To Prime Farmland	To Farmland of Statewide Importance	To Unique Farmland	To Farmland of Local Importance	Subtotal Important Farmland	To Grazing Land	Total Agricultural Land	To Urban and Built-Up Land	To Other Land	To Water Area	Total Converted to Another Use
Prime Farmland [1]	to:	--	24	1	0	25	7,973	7,998	1,300	3,160	0	12,458
Farmland of Statewide Importance [1] [2]	to:	92	--	14	0	106	1,226	1,332	138	2,647	0	4,117
Unique Farmland [1] [2]	to:	1,248	0	--	0	1,248	1,635	2,883	0	1,236	0	4,119
Farmland of Local Importance	to:	0	0	0	--	0	0	0	0	0	0	0
Important Farmland Subtotal		1,340	24	15	0	1,379	10,834	12,213	1,438	7,043	0	20,694
Grazing Land [3] [4]	to:	1,217	176	427	0	1,820	--	1,820	487	1,600	0	3,907
Agricultural Land Subtotal		2,557	200	442	0	3,199	10,834	14,033	1,925	8,643	0	24,601
Urban and Built-Up Land [5]	to:	559	34	3	0	596	383	979	--	1,940	0	2,919
Other Land [6]	to:	3,504	1,247	647	0	5,398	787	6,185	3,115	--	0	9,300
Water Area	to:	0	0	0	0	0	0	0	0	0	--	0
Total Acreage Converted	to:	6,620	1,481	1,092	0	9,193	12,004	21,197	5,040	10,583	0	36,820

[1] Conversion to Grazing Land and Other Land primarily due to land left idle for three update cycles and agricultural boundary adjustments. A portion of the Kern Water Bank accounted for ~3100 acres on the Tupman quadrangle.
[2] Conversions between Important Farmland categories due to corrections made to soil unit identification primarily on the Keene, Cummings Mountain and Tehachapi South quadrangles.
[3] Conversion to Prime Farmland due to new irrigated agriculture and agricultural boundary adjustments made throughout the county.
[4] Conversion to Other Land primarily due to oil field, mine and ranchette boundary adjustments made throughout the county.
[5] Conversions from Urban and Built-Up Land are primarily the result of the ability to obtain a more distinct urban boundary.
[6] Conversion to Prime Farmland and Farmland of Statewide Importance primarily due to newly irrigated agriculture in the Antelope Valley area and agricultural boundary adjustments made throughout the county.

13.1.4.3 Kings County

In 2000, Kings County had a population of 129,500 people. Forecasts show that by the year 2020 Kings County's total population will reach 198,700 (EDD 2002). In 2000, of the 890,786 acres mapped in Kings County, 845,802 were in agricultural use, 28,939 acres were urbanized, 66 acres were water, and 15,979 acres were "other." (FMMP 2002) Table 13-18 summarizes further land use classifications and net changes in land use categories. Kings County defines Farmland of Local Importance as land that supports the commercial activities of dairies, confined livestock, and poultry operations. Table 13-19 specifies land use conversions from one category to another.

Table 13-18
Kings County Land Use Summary and Change by Land Use Category

[1] Conversion to Unique Farmland is due to a correction made to soil unit identification on the Westhaven quad near Lemoore NAS.
[2] Conversion to Farmland of Statewide Importance due to new irrigated agriculture, primarily alfalfa, identified on the Guernsey, Dudley Ridge, and Hacienda Ranch quads.
[3] Conversion to Farmland of Statewide Importance due to new irrigated agriculture found in two water control basins on the Stratford quad and refinements made to urban boundaries.

13.1.4.4 Tulare County

In 2000, Tulare County had a population of 368,000. Forecasts show that by the year 2020 Tulare County's total population will reach 570,900 (EDD 2002). In 2000, of the 1,585,871 acres mapped in Tulare County, 1,314,148 were in agricultural use, 49,378 acres were urbanized, 4,651 acres were water, and 217,694 acres were "other." (FMMP 2002) Table 13-20 summarizes further land use classifications and net changes in land use categories. Tulare County defines Farmland of Local Importance as: lands that produce dry land grains; lands that have physical characteristics that would qualify as Prime or Statewide farmlands except for the lack of irrigation waters; and lands that currently support confined livestock, poultry, or aquaculture operations. Table 13-21 specifies land use conversions from one category to another.

Table 13-20
Tulare County Land Use Summary and Change by Land Use Category

			1998 to 2000 Acreage Changes			
	Total Acreage Inventoried		Acres Lost	Acres Gained	Total Acreage	Net Acreage

[1] Total area inventoried represents information for the new Western Tulare soil survey area (780,415 acres) as well as the Central Tulare area (805,452 acres). Prior reports classified farmland use in Western Tulare County with the Interim mapping categories of Irrigated and Nonirrigated. The County's Farmland of Local Importance definition contains more land use types than Nonirrigated Farmland, thus some Grazing and Other Land in Western Tulare was reclassified into Local.

[2] Conversion to Farmland of Local Importance primarily due to land left idle or utilized for dry grains for three or more update cycles.

13.2 Environmental Consequences/Environmental Impacts

13.2.1 Assessment Methods

Under each alternative, the EWA Project Agencies would negotiate contracts with willing sellers based on a number of factors, including price, water availability, and location. These factors would change from year to year; therefore, the EWA Project Agencies may choose to vary their acquisition strategy in each year. To provide maximum flexibility, this analysis includes many potential transfers when the EWA Project Agencies would not likely need all transfers in a given year. Chapter 2 defines the transfers that are included in the analysis. The primary potential effects of the EWA on agricultural land use relate to crop idling transfers.

Qualitative evaluations in this section discuss the potential changes in land use within the counties that could participate in the EWA. This analysis assesses any permanent conversions of agricultural land to other uses under program conditions relative to the Baseline Condition.

13.2.2 Significance Criteria

This analysis determines that EWA implementation would have significant effects to agricultural land use if an action resulted in:

- Substantial permanent reduction in agricultural acreage in a region or permanent conversion of any lands categorized as Prime Farmland, Farmland of Statewide Importance, or Unique Farmland under the FMMP and Prime Farmland under the Williamson Act.

- Substantial permanent conversion of lands under the Williamson Act or other land protection programs to an incompatible use.

13.2.3 Environmental Consequences/Environmental Impacts of the No Action/No Project Alternative

Under the No Action/No Project Alternative, the trend of land conversion from agricultural uses to urbanization and non-agricultural uses would likely continue and possibly accelerate. Population growth is a major factor resulting in the reduction of agricultural lands. Metropolitan areas in the Central Valley, such as Sacramento, Stockton, Fresno, and Bakersfield are expected to expand with population growth, necessitating further development of land. Recently, farmers have also been affected by urbanization through the water transfer market. Urban water supply reductions and growing populations have increased urban water demand, and lower agricultural prices have increased farmers' willingness to sell.

Under the No Action/No Project Alternative, water transfers involving crop idling would likely continue at recent levels. Generally, water transfers would not affect land use because transfers are temporary. Farming patterns often change annually. If

single year water transfers are made, land use patterns would not vary substantially from normal farming practices. Farmers would also continue to idle some land temporarily depending on crop rotations and the agricultural market. Lands are temporarily removed from farm production for improvements such as land leveling and weed abatement. Farmers also rotate land to reduce pest problems and build soils. Farmers would continue to place back into production other previously-idled land. These continued farming practices would continue to cause some fluctuation in agricultural land use.

Under the No Action/No Project Alternative, statewide and Federal programs to preserve open space and agricultural lands would continue to be implemented. Several programs would also take agricultural land out of production. This would neither interfere with other land protection programs nor bring enrolled lands to an incompatible use. Any actions associated with the No Action/No Project Alternative would be less than significant.

13.2.4 Environmental Consequences/Environmental Impacts of the Flexible Purchase Alternative

The Flexible Purchase Alternative allows transfers up to 600,000 acre-feet and does not specify transfer limits from the Upstream from the Delta Region or the Export Service Area. The transfer from the Upstream from the Delta Region would vary between 50,000 and 600,000 acre-feet each year, limited by hydrologic year type and the availability of conveyance capacity through the Delta each year. Although all potential transfers would not occur within a single year, this section discusses the potential effects of all transfers to the EWA in order to provide an analysis of the maximum transfer scenario. Therefore, the crop idling acreages indicated in the analysis represent maximum crop idling actions and would not likely all occur within one year.

13.2.4.1 Upstream from the Delta

Table 13-22 shows the maximum acreage that could be idled in each county as defined under the project description. (See Chapter 11, Regional and Agricultural Economics for discussion.) EWA purchases through crop idling would not exceed 20 percents of baseline acreages in counties upstream from the Delta. EWA crop idling actions during a single year would likely affect less than the maximum acreages listed in Table 13-22.

Table 13-22
Proposed Maximum Acreages for Rice Idling

	Total Acres of Rice in County	*Acreage Proposed for Idling*	*% of Total*
Butte	95,120	19,000	20.0%
Colusa	132,338	26,460	20.0%
Glenn	83,777	16,750	20.0%
Placer	16,379	3,280	20.0%
Sutter	96,722	19,340	20.0%
Yolo	23,822	4,770	20.0%

Source: DEIM 2002

EWA acquisition of water through crop idling in counties in the Upstream from the Delta Region could permanently decrease the amount of lands categorized as Prime Farmland, Farmland of Statewide Importance, or Unique Farmland under the FMMP and Prime Farmland under the Williamson Act. For land to be categorized as Prime Farmland, Farmland of Statewide Importance or Unique Farmland under the FMMP, the land must have been used for production at some time during the two update cycles prior to the mapping date.[4] Under the Williamson Act, land must have grossed an identified economic value for three of five consecutive years. Crop idling actions by the EWA would not necessarily be done every year. Any crop idling actions would also be a temporary effect. Landowners would annually choose whether to idle their rice fields and could place the fields back into production the following season. Therefore, crops could be idled annually and continue to meet the criteria for Prime Farmland, Farmland of Statewide Importance, or Unique Farmland under the FMMP and Prime Farmland under the Williamson Act.

However, because each parcel has a different cropping history, the EWA Project Agencies could purchase water through crop idling and potentially change the classification of some farmland. This would result in a potentially significant effect. If idling the crops would change the classification to levels less than Prime Farmland, Farmland of Statewide Importance, or Unique Farmland under the FMMP and Prime Farmland under the Williamson Act, the EWA agencies could implement mitigation measures to avoid changing land classifications (See Section 13.2.8). Consequently, land use effects would be less than significant with mitigation.

EWA acquisition of water through crop idling in counties in the Upstream from the Delta Region could convert lands under the Williamson Act and other land resource programs to an incompatible use. As discussed above, crop idling under the EWA would be a temporary effect. Farmers could resume farming the following season after the idling. Therefore, the EWA would not result in any permanent changes to the land and land would not be converted to an incompatible use. Thus, any idling actions would not interfere with objectives of the Williamson Act and other agricultural easements to preserve open space land. In addition, increased net returns allowed by water transfers could help landowners avoid selling land for development and preserve farmland. Consequently, any potential effects to agricultural land use would be less than significant. No mitigation is required.

13.2.4.2 Export Service Area

The majority of cotton fields in the Export Service Area are in Kings, Tulare, Kern, and western Fresno Counties. Table 13-23 provides the maximum number of acres proposed for crop idling in these counties, though these actions would not likely occur in a single year. Refer to Chapter 11, Regional and Agricultural Economics, for further discussion on the development of these acreages.

[4] Each update cycle is two years.

Table 13-23 Proposed Maximum Acreages for Cotton Idling			
	Total Acres of Cotton in County	Acreage Proposed for Idling	% of Total
Fresno	352,880	70,500	20.0%
Kern	246,616	49,300	20.0%
Kings	222,543	44,500	20.0%
Tulare	92,680	18,500	20.0%

Source: DEIM 2002

EWA acquisition of water through crop idling in counties in the Export Service Area could permanently decrease the amount of lands categorized as Prime Farmland, Farmland of Statewide Importance, or Unique Farmland under the FMMP and Prime Farmland under the Williamson Act. Crop idling actions under the EWA would not occur every year. Any crop idling that would take place would be a temporary effect. Landowners could produce cotton in the subsequent season after a crop idling year. Because fields are idled annually, the cotton land could continue to meet the land classification criteria stated in the FMMP and Williamson Act, and permanent reduction to agricultural acreages would not occur.

Because each parcel has a different cropping history, the EWA Project Agencies could purchase water through crop idling and potentially change the classification of some farmland. This would be a potentially significant effect. If idling the crop would change land classification levels under the Williamson Act and FMMP, the EWA agencies could implement mitigation measures to avoid changing land classifications (See Section 13.2.8). Therefore, this effect is considered less than significant with mitigation.

EWA acquisition of water through crop idling in counties in the Export Service Area could convert lands under the Williamson Act and other land resource programs to an incompatible use. As discussed above, crop idling under the EWA would be a temporary effect. Farmers could resume farming the following season after the idling. Therefore, the EWA would not result in any permanent changes to the land and land would not be converted to an incompatible use. Thus, any idling actions would not interfere with objectives of the Williamson Act and other land protection programs to preserve agricultural and open space land. In addition, increased net returns allowed by water transfers could help farmers avoid selling land for development. Consequently, any potential effects to agricultural land use would be less than significant. No mitigation is required.

13.2.4.3 Multi-year Water Transfers

EWA Project Agencies could potentially negotiate multi-year water transfers, which would guarantee the sale of water for multiple years. Multi-year contracts would be negotiated with water districts. If water districts contracted for multi-year crop idling transfers, the EWA acquisitions could change the classification of land under the

FMMP and Williamson Act. This could be a potentially significant effect. The EWA agencies would implement mitigation measures if land classifications under the Williamson Act and FMMP should change. The multi-year contract would indicate land classification requirements and particular parcels would be idled accordingly. Therefore, with mitigation, FMMP and Williamson Act classifications would not be affected by multi-year contracts and the effect would be less than significant. In addition, EWA multi-year transfers would not result in agricultural land being permanently taken out of production or converted to an incompatible use. This effect of multi-year water transfers would be less than significant.

13.2.5 Environmental Consequences/Environmental Impacts of Fixed Purchase Alternative

The Fixed Purchase Alternative specifies purchases of 35,000 acre-feet from the Upstream from the Delta Region and 150,000 acre-feet from the Export Service Area. Although the amounts in each region would be fixed, the acquisition types and sources could vary. This section analyzes the effects of each potential transfer to allow the EWA Project Agencies maximum flexibility when negotiating purchases with willing sellers. These transfers would be the same actions as those described in the Flexible Purchase Alternative, but the amounts would be limited by the total acquisition amount in each region (35,000 acre-feet from the Upstream from the Delta Region and 150,000 acre-feet from the Export Service Area).

The Fixed Purchase Alternative would involve the same crop idling actions as the Flexible Purchase Alternative in areas where 20 percent idling of county rice and cotton acreage defines the limits of transfer acquisitions. This occurs in Placer, Yolo, Kern, Kings, and Tulare Counties.

Table 13-24 describes proposed maximum acreages for rice and cotton idling under the Fixed Purchase Alternative. Under the Fixed Purchase Alternative, the EWA would not result in any agricultural land being permanently taken out of production. The temporary idling of land would not also result in substantial permanent changes in land use classifications under the Williamson Act and FMMP. Consequently, the agricultural land use effects of the Fixed Purchase Alternative would be less than significant.

Table 13-24 Proposed Maximum Acreages for Rice/Cotton Idling for Fixed Alternative				
Region	**County**	**Total Acres of Rice/ Cotton in County**	**Acreage Proposed for Idling**	**Percent of Total Rice/ Cotton Acres to be Idled**
Upstream Region	Butte	95,120	10,600	11.1%
	Colusa	132,338	15,000	11.3%
	Glenn	83,777	15,000	17.9%
	Placer	16,379	3,280	20.0%
	Sutter	96,722	10,600	11.0%
	Yolo	23,822	4,770	20.0%
Export Service Area (Cotton)	Fresno	352,880	65,000	18.4%
	Kern	246,616	49,300	20.0%
	Kings	222,543	29,500	20.0%
	Tulare	92,680	18,500	20.0%

Source: DEIM 2002

13.2.6 Comparative Analysis of Alternatives

The Fixed Purchase Alternative specifies purchases of 35,000 acre-feet from the Upstream from the Delta Region and 150,000 acre-feet from the Export Service Area. While the amounts in each region would be fixed, the acquisition types and sources could vary. To allow the EWA project agencies maximum flexibility when negotiating purchases with willing sellers, this section analyzes the effects of each potential transfer. These transfers are the same actions as those described in the Flexible Purchase Alternative, but the amounts are limited by the total acquisition amount in each region (35,000 acre-feet from the Upstream from the Delta Region and 150,000 acre-feet from the Export Service Area).

Under the No Action/No Project Alternative, conversion of farmland to urban uses would continue under wet and dry years. Water transfers via crop idling would occur under other water acquisition programs. During dry years, crop idling would be utilized more as an acquisition method, relative to wet years.

13.2.6.1 Upstream from the Delta Region

In the Upstream from the Delta Region, the Fixed Purchase Alternative would be limited to a maximum acquisition of 35,000 acre-feet from all sources of water. In most years, this amount could be obtained from stored reservoir water purchases. In those years when surface water assets were not available (in part or in total), the EWA agencies would acquire water first from groundwater substitution and/or groundwater purchase, followed by crop idling. The Fixed Purchase Alternative would not be likely to involve acquisition of water from crop idling. Therefore, during wet and dry years, agricultural land use would not be affected under Fixed Purchase Alternative.

The Flexible Purchase Alternative could involve the purchase of up to 600,000 acre-feet of water from all sources upstream from the Delta. EWA agencies would prefer to purchase water from upstream sources because the water is generally less expensive.

The amount that could be purchased would be limited by the excess capacity of the Delta export pumps to move the water to export areas south of the Delta. During wet years, pump capacity may be available for as little as 50,000 acre-feet of EWA asset water because the pumps would be used primarily to move State and Federal project water to the Export Service Area. During dry years, when there would be less Project water available for pumping (and therefore the pumps would have greater available capacity), the EWA Project Agencies could acquire up to 600,000 acre feet of water from sources upstream of the Delta.

During wet years, the potential for land use effects upstream from the Delta for the Flexible Purchase Alternative would be very similar to the Fixed Purchase Alternative. During wet years, under both alternatives, acquisitions would most likely be from stored water sources and crop idling would not be exercised. There would thus be no land use effects during wet years. During dry year conditions, however, when the export pumps would have greater capacity to move EWA assets, crop idling would be used for additional EWA acquisitions. Consequently, during dry years, under the Flexible Purchase Alternative, EWA Project Agencies would acquire water through crop idling at much greater amounts than would be acquired under the Fixed Purchase Alternative.

13.2.6.2 Export Service Area

EWA asset acquisitions in the Export Service Area under the Fixed Purchase Alternative would be limited to 150,000 acre-feet from stored groundwater and crop idling sources. The EWA agencies would purchase stored groundwater first, then purchase water from crop idling if more were needed. Stored groundwater has finite availability, and 150,000 acre-feet would not likely be available in all years. In years with less stored groundwater availability, EWA agencies would turn to crop idling for the remaining acquisition needs.

EWA asset acquisitions in the Export Service Area under the Flexible Purchase Alternative would be dependent on the water year type upstream from of the Delta. Export pump capacity during wet years would limit the ability of the EWA Project Agencies to move assets through the Delta, requiring reliance on greater purchase amounts from export area sources. During wet years, acquisitions within the Export Service Area could involve up to 600,000 acre-feet of assets. Much of this water would be from crop idling; therefore, potential land use effects of the Flexible Purchase Alternative would be greater than for the Fixed Purchase Alternative.

Table 13-25 compares the potential effects of the Fixed Purchase and Flexible Purchase Alternatives.

Table 13-25
Comparison of Agricultural Land Use Effects for Flexible and Fixed Purchase Alternatives

Region	Asset Acquisition or Management	Result	Effects	Flexible Purchase Alternative Effects	Fixed Purchase Alternative Effects	Significance of Flexible Purchase Alternative	Significance of Fixed Purchase Alternative
Upstream from the Delta: Butte Colusa Glenn Placer Sutter Yolo	Crop Idling	Temporary conversion of rice crops to bare fields	Reduce rice crop acreage in upstream of the Delta counties	Decrease the amount of lands categorized as prime, statewide importance, or unique farmland.	Decrease the amount of lands categorized as prime, statewide importance, or unique farmland. 				Convert lands under the Williamson Act and other land resource programs to an incompatible use.	Convert lands under the Williamson Act and other land resource programs to an incompatible use.	Less than significant effect	Less than significant effect

13.2.7 Mitigation Measures

To decrease adverse land use effects, the EWA would consider the following measures:

- Water would not be acquired from a particular parcel of land if idling the land would result in a lower classification of the land as defined under the FMMP and Williamson Act. The EWA Project Agencies would gather accurate data regarding land classifications of cropland previously idled in participating counties. Data on recent idling history of specific parcels would be obtained from the seller.

13.2.8 Potentially Significant Unavoidable Impacts

There would be no potentially significant unavoidable agricultural land use effects.

13.2.9 Cumulative Effects

The timeframe for the EWA cumulative analysis extends through 2007. The cumulative effects analysis considers other water transfer programs that utilize crop idling and conservation programs that protect agricultural and open space land. These programs include the Dry Year Purchase Program, the Drought Risk Reduction Investment Program, CALFED Environmental Water Program and the CVPIA Water Acquisition Program. Chapter 22 explains the framework of the cumulative analysis and a summary of the programs considered.

Crop idling in these water acquisition programs is on a voluntary, year-by-year basis. Farmers can choose to offer their water for sale to any of the above programs during any season that the programs are in operation, subject to project conditions. The farmers can then decide to resume planting in the subsequent season. Therefore, crop idling would be a temporary effect and would not permanently alter any land use patterns. Water acquisition programs also would not result in any land being converted to incompatible uses. Land classifications could change under the cumulative condition if parcels are repeatedly idled under other programs. This is a potentially significant cumulative effect.

However, with the mitigation measures identified above, any EWA water acquisitions via crop idling would not decrease the amount of land categorized as Prime, Statewide Importance, or Unique under the FMMP and Prime Farmland under the Williamson Act. Therefore, EWA would not permanently change land use practices and would not contribute to any potential cumulative effects. Consequently, because crop idling is temporary and EWA actions would not result in any changes to land use classifications, any potential cumulative effects on agricultural land use by the EWA would be less than significant.

The Westlands Global Land Settlement Program is a land retirement program that proposes to permanently remove 200,000 acres of cropland from production in western Fresno and Kings Counties. Currently, the program does not specify the types and locations of cropland intended for retirement. Any land retired under the program would be used for wildlife habitat or dryland farming. The retirement program likely would change land classifications, depending on the location and current classification of the land. If changes occur, a cumulative effect could be considered significant. Environmental documentation for the program should address the potential cumulative effect. With the mitigation measures identified in this chapter, the EWA would not contribute to the cumulative effect.

Chapter 14
Recreation Resources

Water-enhanced and water-dependent recreational activities, such as wildlife viewing, fishing, hunting, swimming, motor boating, sailing, and windsurfing, are popular throughout California. The quality of recreation at lakes and reservoirs depends largely on surface water levels. Rafting and boating are popular activities that are often dependent on high river flows/reservoir levels for maximum enjoyment. Enjoyment of water-enhanced activities, such as picnicking and hiking, can also be related to higher water levels.

This chapter discusses the effects of the Flexible Purchase and Fixed Purchase Alternatives on recreation resources. Section 14.1 presents the affected environment/existing conditions and Section 14.2 evaluates the No Action, Flexible Purchase, and Fixed Purchase Alternatives, including comparative analysis of the alternatives and cumulative impacts.

14.1 Affected Environment/Existing Conditions

14.1.1 Area of Analysis

Effects are assessed in the Upstream from the Delta Region, Delta Region, and in the Export Service Area. This discussion focuses on the areas where EWA actions would take place (Figure 14-1):

- Upstream from the Delta Region: Lake Shasta; Little Grass Valley and Sly Creek Reservoirs; Lake Oroville; New Bullards Bar Reservoir; French Meadows and Hell Hole Reservoirs; Folsom Lake; Lake McClure; Sacramento, Feather, Yuba, American, and Merced Rivers; Waterfowl hunting areas in Glenn, Colusa, Yolo, Sutter, Butte, and Placer Counties.

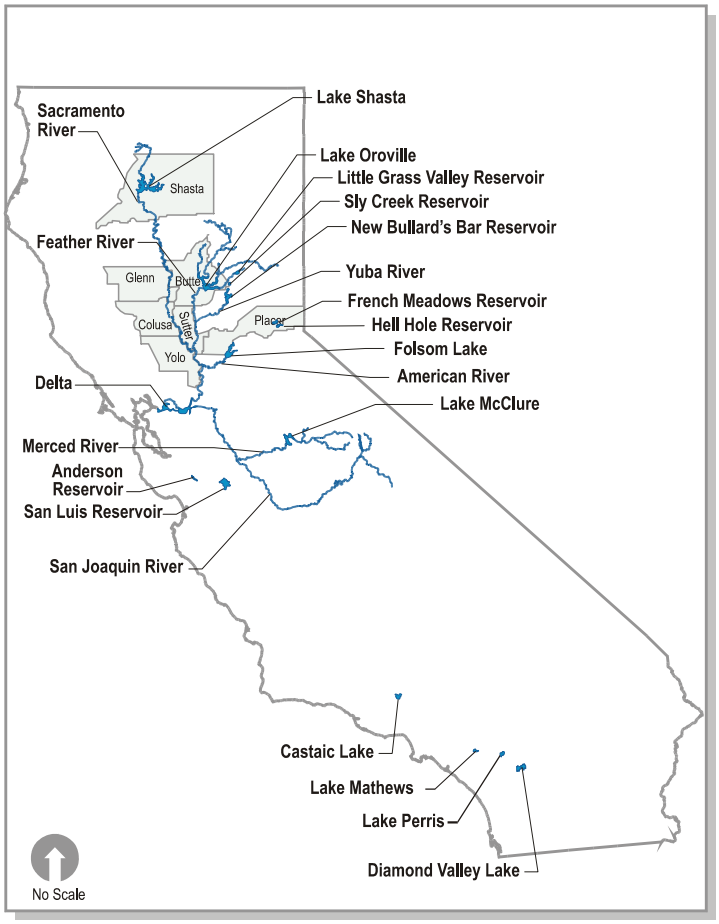

Figure 14-1
Recreation Area of Analysis

- Delta Region

- Export Service Area: Anderson Reservoir, San Luis Reservoir and O'Neill Forebay; Lake Perris; Castaic Lake; Diamond Valley Lake; Lake Mathews.

14.1.2 Upstream from the Delta Region

Major recreation areas in the Upstream from the Delta Region can be found at lakes and reservoirs, rivers and streams, federal wildlife refuges, and state wildlife management areas (WMAs). River flows and reservoir levels tend to be highest in late spring and early summer and taper off toward fall, somewhat reducing the quality or availability of recreational activities such as rafting and boating. Water-based and water-enhanced activities are more prevalent during the summer months when the air temperature is warm; however, fishing and wildlife viewing are year-round activities.

14.1.2.1 Hunting and Fishing

This discussion focuses on the types of hunting and fishing in areas where EWA actions could take place, including the reservoirs and rivers mentioned above and rice fields.

Many duck clubs are established on flooded rice fields during the winter because of the large number of waterfowl that flock to the rice fields for forage and habitat. In 2001, approximately 45,000 hunter visits to 11 sites within the EWA program area were reported by the Department of Fish and Game. Approximately two waterfowl (ducks, geese, or coots) were shot per hunter. Regulations vary by bird species; however, the hunting season generally spans from late October through January.

Reservoirs and rivers provide habitat for cold- and warm-water fish. Anglers fish for striped bass, salmon, sturgeon, steelhead, trout, Kokanee salmon, bass, crappie, bluegill, catfish, and others. The California Department of Fish and Game publishes a fishing regulation booklet each year that summarizes the allowable fishing season, take limit, and other guidelines specific to each species. Fishing is popular year-round; however, the species caught may vary during different times of the year. According to the California Department of Fish and Game, more than 2.2 million anglers purchase some type of fishing license each year.

14.1.2.2 Sacramento River

The upper Sacramento River and major upstream reservoirs (Shasta and Keswick) are important recreational resources for the Sacramento Valley and beyond. These resources support a broad range of water-dependent and water-enhanced recreation opportunities, including facilities for boating, fishing, swimming, and camping.

Fishing, rafting, canoeing, kayaking, swimming, and power boating are available along most of the upper Sacramento River. Whitewater rafting and other boating opportunities are dependent on river flows above 5,000 cubic feet per second (cfs).

Additional recreational activities along the Sacramento River include hiking, wildlife viewing, and camping.

Between Colusa and Sacramento, major recreational facilities exist at the Colusa-Sacramento River Recreation Area, Colusa Weir access, Tisdale Weir access, River Bend Boating Facility, Knights Landing, Sacramento Bypass, and Elkhorn Boating Facility. The Colusa-Sacramento River State Recreation Area provides 60 acres of riverfront recreation near the City of Colusa and contains the only public boat launch and landing facility in Colusa County. The park is at the north end of town where the river makes a wide easterly bend. Its key features are boat ramps, picnic sites, nature trails, and campsites. The river's width at the park provides room for a variety of water activities, including fishing, boating, and waterskiing.

Wildlife refuges along the Sacramento River provide fishing, hunting, and wildlife viewing opportunities. These refuges include Sacramento, Colusa, Sutter, and Delevan National Wildlife Refuges (NWRs) and Gray Lodge WMA. Gray Lodge WMA is the most popular of the five refuges in the region. Non-consumptive (photography and hiking) and consumptive (fishing and hunting) uses historically have been equally popular at the refuges, each accounting for approximately 50 percent of the total use. Sutter and Delevan NWRs are used almost exclusively for hunting.

The lower Sacramento River constitutes the reach between the American River confluence and the Delta. As a recreational resource, its use is associated closely with recreational use of Delta waterways. This lower reach of the river, influenced by tidal action like the Delta, is a popular boating and fishing area with dispersed public access, several private marinas, and extensive boat traffic, particularly in the summer.

14.1.2.2.1 Lake Shasta

The U.S. Forest Service administers Lake Shasta and Keswick Reservoir. The four large arms of Lake Shasta are the Pit River, Squaw Creek, McCloud River, and Sacramento River. Recreational facilities on Lake Shasta include 27 designated campgrounds, 4 picnic areas, 7 public boat ramps, and 11 private marina resorts. The boat ramps extend to varying elevations. For example, Bailey Cove boat ramp is available until 50 feet of drawdown occurs, whereas Jones Valley and Centimudi are available to 210 feet of drawdown. Low lake levels affect campsite accessibility before boat ramps are affected (Grigsby 2003). Recreation activities on Keswick Reservoir are primarily boating and fishing, with little development other than one boat ramp.

14.1.2.3 Feather River

Activities such as swimming, fishing, camping, bird watching, picnicking, and bicycling are popular along the Feather River. Rafting on the North and Middle Forks of the Feather River runs from January to April or May, depending on flow. Summer rafting and kayaking occurs on the North Fork depending on upstream PG&E reservoir operations, though lower flows in these reaches allows recreationists to use inner tubes to float down the river. The section of the Feather River between the

Thermalito Diversion Dam and Thermalito Afterbay outlet is commonly referred to as the Low Flow Channel of the Feather River (Figure 14-2). Fishermen, wildlife and birdwatchers, sightseers, hikers, and bicyclists enjoy recreation along the Low Flow Channel. The Brad P. Freeman Trail runs beside this section of river from the Diversion Dam to Highway 162. This section is an important recreational resource for the residents of Oroville and nearby areas. Based on California Department of Fish and Game regulations, the river is open for fishing north of the Table Mountain Bicycle Bridge. In the spring and fall, salmon are known to congregate at the Thermalito Afterbay outlet. In recent years, the Feather River has served as habitat to 40,000 Chinook salmon in the spring and fall. Downstream from the Thermalito Afterbay outlet, the river continues through the Oroville Wildlife Area. The Oroville Wildlife Area provides opportunities for bird watching, in-season hunting, fishing, swimming, and camping.

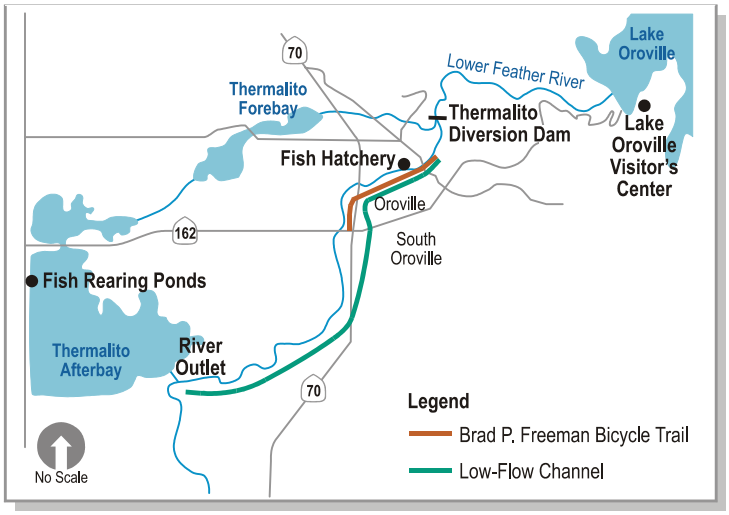

Figure 14-2
Lake Oroville and Vicinity

14.1.2.3.1 Little Grass Valley and Sly Creek Reservoirs

Little Grass Valley Recreation Area in the Plumas National Forest offers recreationists a wide variety of outdoor experiences, including camping, picnicking, fishing, waterskiing, swimming, boating, hunting, hiking, sightseeing, and winter sports such as snowmobiling and cross-country skiing. Camping is provided at Running Deer, Red Feather, Little Beaver, Wyandotte, Peninsula Tent, and Black Rock Campgrounds. Boat ramps include Maidu, Tooms, and Black Rock. The Maidu boat ramp is above water and usable when the reservoir is above 50,000 acre-feet. Tooms and Black Rock boat ramps are operable when reservoir levels are above 55,000 acre-feet (DWR 2000). Low reservoir levels affect use of boat ramps prior to affects on swimming beaches or campgrounds (Humphreys 2003). Blue Water and Pancake Beaches provide changing pavilions, restrooms, and parking. Trout varieties in the lake include brown and rainbow trout. Catfish and other warmwater species are also present.

Sly Creek Reservoir is in eastern Butte County, 35 miles east of Oroville. Recreation at Sly Creek Reservoir includes camping, hiking, picnicking, swimming, fishing, and boating. Mooreville boat ramp provides access to the reservoir and remains operable while water levels are above elevation 3,479 feet mean sea level (msl). The reservoir is managed to maintain elevations above 3,480 through July (Braxton 2002). Low

reservoir levels affect use of boat ramps prior to affects on swimming beaches or campgrounds (Humphreys 2003). The California Department of Fish and Game regularly stocks the reservoir with fish, including rainbow trout, brown trout, and Kokanee. Sly Creek and Strawberry campgrounds have a combined total of 40 campsites. These campgrounds were developed by Oroville Wyandotte Irrigation District (ID) and are operated by a Plumas National Forest concessionaire.

14.1.2.3.2 Lake Oroville

Lake Oroville is the second largest reservoir in California and is the keystone of the SWP. Lake Oroville, Thermalito Diversion Pool, Thermalito Forebay, Thermalito Afterbay, and the Oroville Wildlife Area all compose the Lake Oroville Complex that distributes water and electrical power to various destinations. Lake Oroville has two full-service marinas; nine parks provide facilities for baseball, tennis, swimming, and picnicking within the lake's vicinity. Figure 14-3 shows the major recreational areas and facilities at Lake Oroville. There are major boat launch ramps at Bidwell Canyon, Loafer Creek, and Lime Saddle (DWR 2001). The Spillway has an 8-lane and a 12-lane ramp in two stages. New extensions constructed in 2002 on boat ramps at Bidwell Canyon, the Spillway, and Lime Saddle allow the ramps to remain open when lake elevations remain above 700 feet msl (Knox 2003). Average water surface elevation in Lake Oroville has historically been between 817 feet msl and 787 feet msl between July and September, respectively. Although boat ramps remain usable, lower lake elevations can adversely affect swimming beaches and boat in campgrounds (Sherman 2003). The Lake Oroville State Recreation Area provides camping, picnicking, boating, fishing, hunting, horseback riding, hiking, bicycling, sightseeing, and a variety of other activities. Major facilities in the State Recreation Area include Loafer Creek, Bidwell Canyon, Spillway, Lime Saddle, Lake Oroville Visitor Center, and North and South Themalito Forebay. Additionally, the Recreation Area provides several less-developed car-top launching areas, 84 boat-in campsites, and 10 floating campsites on Lake Oroville. Nearby, DWR maintains three launch ramps and a day-use area at the Oroville Wildlife Area, which includes Thermalito Afterbay.

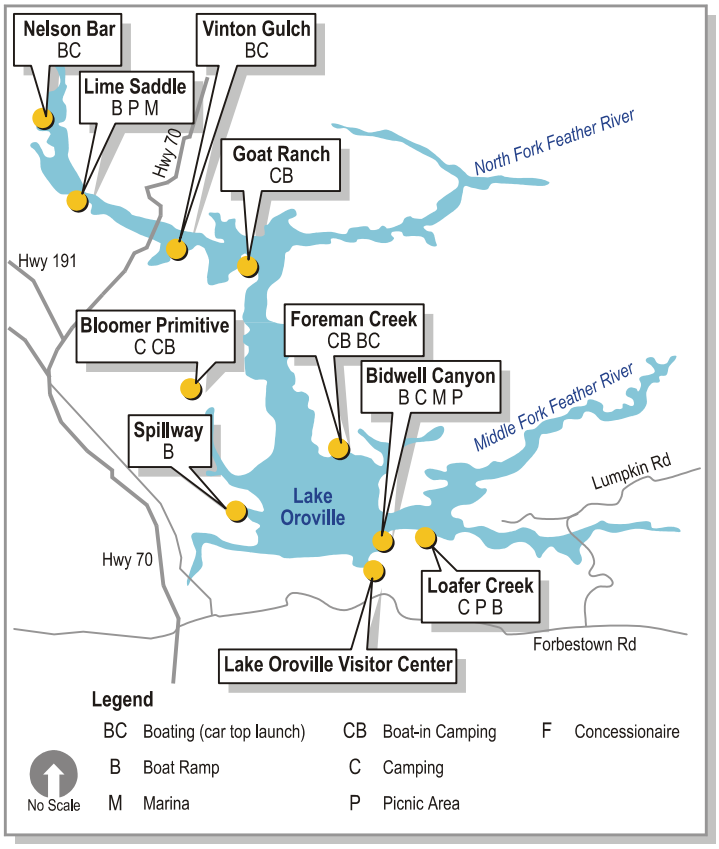

Figure 14-3
Major Recreational Areas at Lake Oroville

Water levels affect recreational opportunities. As water levels decrease, opportunities for operable boat launch ramps, car-top boat launches, swim beaches, and boat-in camps can decrease. Low water levels also impair boat access to Feather Falls, a spectacular attraction on the Fall River, a Feather River tributary.

14.1.2.4 Yuba River

Numerous rivers, creeks, tributaries, and reservoirs along the Yuba River offer recreation opportunities and receive extensive use. Boating in the Yuba River is limited because of poor access; boats must be hand-carried to the river. Where access is available, fishing, picnicking, rafting, tubing, and swimming are the dominant recreational uses. The Yuba River offers excellent American shad, Chinook salmon, and steelhead fishing.

14.1.2.4.1 New Bullards Bar Reservoir

New Bullards Bar Reservoir is approximately 21 miles north of Nevada City, in historic gold country. This reservoir is popular for boating, fishing, and camping. Over 20 miles of hiking and mountain biking trails exist in the area, including Bullards Bar Trail, which runs along the perimeter of the lake. Several campgrounds, including Schoolhouse and Dark Day, are in the vicinity. Some campgrounds around the reservoir, such as Madrone Cove and Garden Point, are accessible by boat only. Emerald Cove Resort and Marina is a floating marina that is operable at all lake levels. The marina offers a general store, pumping station, launch ramp, boat rentals, moorage, and annual slips. Boat access to the reservoir is provided by the Cottage Creek boat ramp (at Emerald Cove Marina) and Dark Day boat ramp. Cottage Creek boat ramp is unusable when the lake level falls below 1,822 feet mean sea level (msl), and Dark Day boat ramp becomes inoperable when the lake level falls below 1,798 feet msl (Onken 2003). Low reservoir levels affect day swimming areas and boat in campgrounds before boat ramps are affected. Fish species found in the reservoir include rainbow trout, brown trout, Kokanee salmon, smallmouth bass, largemouth bass, bluegill, crappie, and bullhead catfish. Some boat launchings occur year round; however, the typical boating season extends from about early May through mid October. The heaviest use of the ramps occurs on weekends and holidays from Memorial Day to Labor Day (U.S.D.A Forest Service 1999).

The Tahoe and Plumas National Forests total more than 56,000 acres of land in the Yuba River watershed. The forests offer hunting, fishing, camping, hiking, and other recreational opportunities. The 11,200-acre Spenceville Wildlife Area, managed by the California Department of Fish and Game, provides picnicking, fishing, hunting, and hiking.

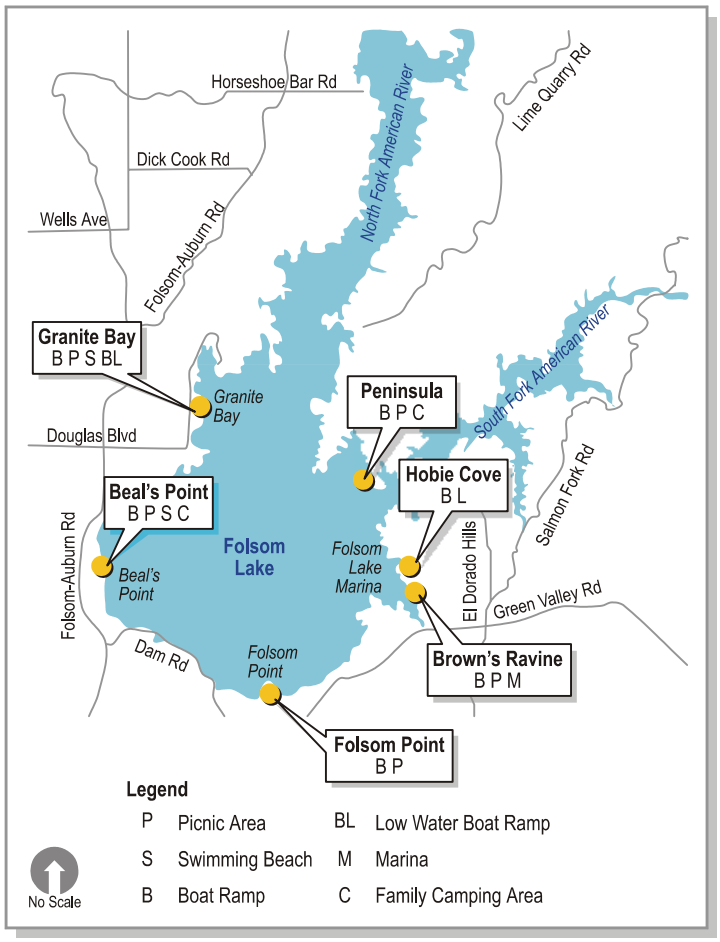
14.1.2.5 American River

On the Middle Fork of the American River, commercial rafting is available upstream from the confluence of the North and Middle Forks. The minimum threshold for whitewater boating is 850 cfs (EDAW and SWRI 1999).

Recreation facilities on the lower American River are generally along the American River Parkway. The lower American River is the focus of the parkway that extends from Nimbus Dam to Discovery Park. The parkway consists of 14 interconnected parks, a continuous trail system, and contains 5,000 acres**.** The parkway is recognized as one of the Nation's premiere urban parkways (PCWA 2001). The most popular feature is the Jedediah Smith Memorial Bicycle Trail that extends approximately 32 miles from Discovery Park on the lower American River to Beal's Point at Folsom Reservoir.

Additional recreation facilities include pedestrian/equestrian trails and picnic areas throughout the parkway. Water-dependent facilities consist primarily of trailered-boat and car-top boat launching facilities. Fishing is permitted in the parkway year round except during fall and early winter, when portions of the river are closed to protect spawning fish. The parkway contains no commercial recreation facilities, although raft rental outfitters are located nearby. The boating and rafting season is generally between April and October, with peak raft rentals in June, July (highest use month), and August (PCWA 2001). The minimum/maximum flow range for adequate whitewater rafting and boating opportunities on the lower American River is 1,750 cfs to 6,000 cfs. The optimum range is slightly higher, 3,000 cfs to 6,000 cfs (EDAW and SWRI 1999). Owned and managed by the County of Sacramento, the parkway is linked to additional parklands from Nimbus Dam to Folsom Reservoir. The California Department of Parks and Recreation manages the latter parklands.

14.1.2.5.1 French Meadows and Hell Hole Reservoirs



French Meadows Reservoir, which is on the Middle Fork of the American River, provides recreation opportunities for camping, boating, picnicking, horseback riding, and hiking. The reservoir provides boat access via two launch sites. The boat ramps become unusable when the storage drops below elevation 5,196 feet (Neary 2002). Low water levels affect boat ramps before beaches or boat-in campgrounds (Hill 2003). Fishing for rainbow and brown trout is a popular activity.

Hell Hole Reservoir is in the Eldorado National Forest on the Rubicon River, a tributary of the American River. The primary recreation activities on this reservoir are camping and fishing; a variety of trout are available in the lake. One boat launch ramp suitable for small craft is accessible when storage in the reservoir is above elevation 4,537 feet (Jones and Stokes 2001). Fifteen boat access sites (for small craft) are also available on the lake. Low water levels affect boat-in campgrounds before boat ramps are affected (Jue 2003).

14.1.2.5.2 Folsom Lake

Folsom Lake is in the Folsom Lake SRA, which is managed by the California Department Parks and Recreation. When full, Folsom Lake has about 11,900 surface-acres of water and extends nearly 15 miles up the North Fork of the American River and 10.5 miles up the South Fork. Folsom Lake has 75 miles of undeveloped shoreline, including many areas available for swimming. Summer surface water temperatures

are warmer than inflowing water or water released downstream to Lake Natoma, so the surface water becomes warm enough for comfortable swimming.

Source: EDAW and SWRI 1999

Figure 14-4
Folsom Lake SRA Facilities

Folsom Lake has recreation facilities for boat launching, mooring, swimming, hiking, bicycling, picnicking, camping, fishing, and nature study (Figure 14-4). A majority of the water-dependent recreational facilities are at Beal's Point, Granite Bay, Peninsula Campground, Brown's Ravine, and Folsom Point (formerly Dike 8). Approximately 80 miles of trails are available for hiking and horseback riding, including an 8-mile paved bicycle trail that connects with the American River Parkway's 26-mile Jedediah Smith Bicycle Trail (see below). Also of note is the 7.7 mile Darrington Mountain Bike Trail that follows the Folsom Lake shoreline from the South Fork of the American River to the Peninsula Campground.

The primary commercial recreational facility on Folsom Lake is the Folsom Lake Marina in Brown's Ravine. The only marina on the lake, Folsom Lake Marina provides approximately 685 wet slips and 45 dry slips for both sailboats and powerboats. The wet slips are operable when the lake level is at least 412 feet msl elevation (PCWA 2001). The slips can accommodate boats up to 28 feet in length. Small craft rental and supplies are also available at the marina. In addition, concessionaires operate snack bars and recreational equipment rentals at the Beal's Point and Granite Bay swimming beaches during the peak summer season.

The water surface elevation in Folsom Lake affects the availability of boat ramps, beaches, berth sites, and other facilities that depend largely on water depth or surface

area. Boat ramps and swimming beaches are affected simultaneously as water levels recede (Nakaji 2003).

14.1.2.6 Merced River

Recreational opportunities along the river are very limited (Stillwater Sciences and EDAW 2001). Most parks and recreation spots are located within agricultural and grazing land areas. Two percent of the land area in the Merced River corridor is publicly owned, although much of this land does not offer recreational opportunities or public access to the river (Stillwater Sciences 2002). There are five parks and public access points downstream from Crocker-Huffman Dam to the confluence with the San Joaquin River, Cuneo Fishing Access, Henderson County Park, McConnell SRA, Hagaman County Park, and George Hatfield SRA. Recreational opportunities at these parks include boating, canoeing, rafting, fishing, swimming, camping, and picnicking. Most of these activities occur primarily during the summer, typically May through September.

14.1.2.6.1 Lake McClure

Lake McClure offers boating and waterskiing, camping, fishing, and hiking. Barrett Cove Marina on Lake McClure is the largest recreational facility on the lake. It has year-round houseboat and patio boat rentals as well as rentals for other watercraft. McClure Point overlooks the largest span of Lake McClure, offering many water sports and activities. There is one boat ramp at McClure Point, two boat ramps at Barrett Cove, and one boat ramp at both Horseshoe Bend and Bagby recreation area. The boat ramps at lake McClure cease operation when the reservoir reaches elevation 793 feet (Bagby); 758 feet (Horseshoe Bend); 650 feet (McClure Point); 630 feet (southern Barrett Cove); 590 feet (northern Barrett Cove and Piney Creek) (San Joaquin River Group 1999). Low water levels affect boat ramps before swimming beaches (Latronica 2003).

14.1.3 Delta

Boating, hunting, sport fishing, and other water-based activities are the most important recreational activities in the Delta. The facilities available to boaters and other recreational users include marinas, city or county public access areas, and yacht or ski clubs. The increasing demand for Delta recreation opportunities spurred the state to establish Brannan Island SRA in 1965 and Franks Tract SRA in 1966.

Historically, year-round sport fishing from shore locations, piers, and boats has been a major activity in the Delta. According to the Delta Protection Commission, sport fishing tournaments are an important recreational activity that contribute to the local economy. Important sport fishing species include striped bass, shad, black bass, catfish, salmon, and steelhead.

Most of the navigable waterways in the Delta are public, and most of the land is private. The lack of public lands limits the use of the Delta for recreation. Public use of the Delta is concentrated in a few areas where marinas and other facilities provide recreational opportunities and access to the Delta waterways and at roadside areas

where public roads are adjacent to the waterways. There are few public parks. Some of the recreation areas in the Delta are accessible only by boat, thus limiting access to the Delta for some users, such as shore anglers.

About 120 marinas account for most of the recreational facilities in the Delta. In addition to berthing and boat fuel, marinas provide services including ski boat and houseboat rentals; boat services (such as boat launching) and marine supplies; camping and picnicking facilities; guest docks; and food and beverage services. Marinas are not equally distributed throughout the Delta but are concentrated in a handful of locations. The most heavily used areas include Bethel Island in Contra Costa County and Lower Andrus Island in Sacramento County. Bethel Island is very congested, with resorts and 33 marinas providing 1,185 berths. In addition to marina berths, the private facilities at Bethel Island include a large number of support and service facilities. Andrus Island is more rural but provides nearly 1,700 berths.

Popular access points for boating, waterskiing, and riding personal watercraft include Windmill Cove near SR 4; King Island; Paradise Point; Herman & Helens near Eight Mile Road; Tower Park near SR 12; and Del's Boat Harbor near the city of Tracy. Houseboating also is concentrated along Eight Mile Road. Windsurfing, a popular sport in the Delta, typically occurs along SR 160 between Sherman Island and Rio Vista and at Windy Cove. Windy Cove is a new facility constructed at Brannan Island SRA and is the only formal windsurfing site in the area.

Not all recreational activities in the Delta are associated with water. The more popular land-based recreation activities include hunting, camping, picnicking, walking for pleasure, bicycling, wildlife viewing, photographing wildlife, sightseeing (driving for pleasure), and attending special events. Waterfowl and pheasant are hunted at wildlife management areas including Grizzly Island, Joice Island, and Sherman Island, in addition to a variety of state cooperative hunting areas.

Much of the open space in the Delta is used for public parks and wildlife refuges. The California Department of Parks and Recreation owns 5,000 acres in the Delta, including Brannan Island, Franks Tract (flooded), Delta Meadows (a scenic waterway near Locke that is popular with boaters), and over 1,000 acres in the Stone Lakes NWR. State, Federal, and nonprofit agencies have purchased significant acreage in the Delta in recent years for enhancement and management as wildlife habitat. For example, California Department of Fish and Game owns 8,080 acres of land in the Delta, including underwater land in the Lower Sherman Island Wildlife Area, portions of the Yolo Bypass, Woodbridge Ecological Reserve, Calhoun Cut Ecological Reserve, and Webb Tract berms and islands.

14.1.4 Export Service Area

14.1.4.1 Anderson Reservoir

Santa Clara Valley Water District leases Anderson Reservoir to the Santa Clara County Parks and Recreation Department who maintain jurisdiction over the Anderson Reservoir County Park. The provisions of the lease provide the District

flexibility to operate Anderson Reservoir. District Resolution 605 establishes a minimum summer pool of 20,000 acre-feet for recreation. Anderson Lake Park has power and non-power boating, water skiing, picnic areas, and barbeque facilities. The 2,365-acre park also includes Coyote Creek multiple use trails, Jackson Ranch historic park site, Moses L. Rosendin Park, and the Burnett Park area. A new 60-foot wide, four-lane boat launch ramp (scheduled for completion in the fall of 2003) will replace the original boat ramp built in the mid-1950s.

14.1.4.2 San Luis Reservoir

San Luis Reservoir and O'Neill Forebay provide for activities such as boating, waterskiing, fishing, camping, and picnicking. San Luis Reservoir SRA is open year round. Boat access is available via one boat ramp at the Basalt area at the southeastern portion of the reservoir and at Dinosaur Point at the northwestern portion of the reservoir. The boat ramp at Basalt becomes difficult to use because of low reservoir levels at elevation 340 feet; the boat ramp at Dinosaur Point is difficult to access at elevation 360 feet (San Joaquin River Group 1999). There are no designated swimming areas or beaches at San Luis Reservoir, but O'Neill Forebay (with its stable surface elevation) has popular swimming, boating, fishing, and camping opportunities.

14.1.4.3 Lake Mathews

Lake Mathews is in Riverside County between Interstate 15 and Interstate 215. Metropolitan Water District (WD) completed Lake Mathews Reservoir in 1939 as the western terminus for the Colorado River Aqueduct. The Lake Mathews – Estelle Mountain Reserve, approximately 13,000 acres, surrounds the lake and is managed jointly by Metropolitan WD, the Riverside County Habitat Conservation Agency, U.S. Bureau of Land Management, and the California Department of Fish and Game. Public access on the Reserve is permitted only on non-Metropolitan WD lands and only by foot or horse travel; there is no public recreation on the lake.

14.1.4.4 Castaic Lake

Castaic Lake is in the Castaic Mountains in southern California and has 29 miles of shoreline. Castaic Lake and Lagoon provide many opportunities for recreation. With two boat launch ramps, the upper lake offers visitors a wide range of water sports, such as sailing, waterskiing, powerboating, and fishing. The east ramp is usable (above water) when the surface elevation is above elevation 1,325 feet msl. The west ramp becomes unusable earlier, at surface elevation 1,435 ft msl (Leahigh 2002). Table 14-1 lists potential recreation effects caused by low water levels that occur in many years. Castaic Lake supports largemouth bass, bluegill, trout, crappie, and catfish. Castaic Lagoon, south of Castaic Lake, serves as a recreation area and a groundwater recharge basin. Overnight camping is available at the lagoon, which features sandy beaches, grassy picnic areas, and a two-lane boat launching ramp. Boating in Castaic Lagoon is limited to non-power boats only; sailing, canoeing, and fishing are popular activities in this area.

Table 14-1 Potential Recreation Effects at Castaic Lake State Recreation Area due to Changes in Surface Water Level	
Lake Surface Water Level (feet)	**Potential Effects**
1,515	Maximum operating surface elevation.
1,495	Potential for significant propeller damage to boats from exposed hazards begins and increases rapidly as the water elevation drops farther.
1,490	Two of the largest boat-in picnic areas on the lake, Sharon's Rest and Laura's Landing, become inaccessible unless willing to climb very steep shoreline.
1,480	Surface area of the lake is decreased by over 10 percent. Existing conflicts between user groups during heavy use periods would be exacerbated. Waiting lines for launching, which frequently occur during heavy use periods even at full lake capacity, would increase.
1,460	The west boat launch ramp loses two of its six lanes.
1,456	Of approximately 25 mapped lake hazards, half would be exposed. Hazard areas are to be avoided when water levels are within 5 vertical feet of hazard elevation.
1,450	The east (main) launch ramp begins to lose lanes, adversely affecting concessionaire's rental boat operation.
1,435	The west boat launch ramp becomes completely unusable. Additional pressure is placed on the main launch ramp and the potential for waiting lines for launching boats is greatly increased.
1,428	Approximately 75 percent of lake hazard areas would be exposed.
1,280	Minimum operating surface elevation.
1,280	Dead pool surface elevation.

Source: Central Coast Water Authority 1995

14.1.4.5 Lake Perris

Lake Perris is southeast of Los Angeles and is the southern terminus for the State Water Project's East Branch of the California Aqueduct. The lake has 10 miles of shoreline that provides opportunities for swimming, boating, fishing, picnicking, bicycling, horse riding, waterskiing, scuba diving, rock climbing, and hunting. Elevations of the boat ramps on the lake are listed in Table 14-2.

Table 14-2 ***Lake Perris Boat Ramps***	
Boat Ramp	***Elevation (ft above msl)***
Ramps 1-4	No record
Ramp 5	1,554
Ramp 6	1,535
Ramp 7	1,566
Power Cove	1,579

Source (Leahigh 2002)

Swimming and playground facilities are available at the Moreno and Perris beaches. The Bernasconi Pass area has picnic facilities and camping sites. The "Big Rock" rock climbing area is also in this vicinity. Fish species in the lake include rainbow trout,

catfish, and Alabama spotted bass. The Lake Perris area also offers hunting for such upland game as valley quail, mourning dove, ducks, geese, and rabbits.

Stakeholders established a task force to manage needs regarding water supply, level, quality, and use at Lake Perris. Maintaining water levels to provide for adequate recreational opportunities was a priority for the Department of Parks and Recreation. The Department of Fish and Game, Riverside County Department of Health, Department of Water Resources, Metropolitan Water District, and the California Department of Boating and Waterways also have priorities for management of water coming into and out of Lake Perris. When water levels are low, recreational opportunities (such as for boating) can be reduced. Normal operations can trigger these low water levels. Also, water quality concerns arising from low water levels affects permitted use of the lake (Arroyo 2002). Table 14-3 lists potential recreation effects caused by low water levels.

Table 14-3 Potential Recreation Effects at Lake Perris State Recreation Area Due to Changes in Surface Water Level

Lake Surface Water Level (feet)	Potential Effects
1,588	Maximum operating surface elevation.
1,574	Guest boat slips at marina would not be usable.
1,573	Non-guest boat slips at marina would not be usable. Exposed hazards would begin to cause potential vessel damage. Increased safety risks to boating public and personal watercraft from reduced surface area and increased hazards.
1,570	Watercraft and windsurfing would be adversely affected as mud and silt layers are within the wading zone where users access the beach for launching. Swimming would be adversely affected by reduced aesthetics, odor, and unpleasant beach conditions, due to exposure of wading zone. Hazards from exposed clam bed and vegetation. Habitat and cover would be exposed and begin to affect sportfishing. Shore fishing would be affected due to increased difficulty of accessing the lake.
1,565	Exposure of numerous underwater hazards would result in 50 percent reduction in the area available for waterskiing and the recreational use of personal watercraft.
1,560	Launch ramp exposed. Most boat-in facilities would be unusable due to exposed mud, underwater vegetation, and hazards. Use conflicts would be significantly increased. Normal operating capacity of 500 vessels would be decreased due to reduced water surface area. Boater delays, which are currently up to four hours or more on weekends during May through October, would be increased.
1,544	Water intake for park's domestic water supply would become inoperable, affecting both park users and employees' residences.
1,540	Minimum operating surface elevation.
1,500	Dead pool surface elevation.

Source: Central Coast Water Authority 1995

14.1.4.6 Diamond Valley Lake

Diamond Valley Lake is between Temecula and Hemet and spans 4.5 miles. The lake has recently been filled; recreation facilities have not yet been constructed. Recreation may eventually include opportunities for biking, hiking, camping, fishing, sailing, boating, and golfing. Facilities at Diamond Valley Lake will likely also include special event areas and separate swimming pools and lagoons.

14.2 Environmental Consequences/Environmental Impacts

14.2.1 Assessment Methods

Under each alternative, the EWA Project Agencies would negotiate contracts with willing sellers based on a number of factors, including price, water availability, and location. These factors would change from year-to-year; therefore, the EWA Project Agencies may choose to vary their acquisition strategy in each year. Maximum flexibility is provided by including in this analysis many potential transfers when the EWA Project Agencies would likely not need all transfers in a given year. Chapter 2 defines the transfers that are included in this analysis.

The effects analysis uses both quantitative and qualitative methods to assess changes in recreational opportunities and use of affected facilities. Quantitative methods include consideration of thresholds at which recreational opportunities are affected (e.g., the reservoir level at which boat ramp use declines or boat ramps become unusable). The comparison of reservoir storage elevations and river flows uses median values over the period of record and current operating parameters as a baseline. This method supplies the most average result; 50 percent of the time actual reservoir and river levels will be higher and 50 percent of the time the actual levels will be lower than those used in the baseline. If the reservoir and river levels differ greatly from the historic level during a transfer year, the effects will also differ from those predicted by the analysis. If reservoir levels are higher than the historical average, the actual effects will be less than the predicted effects. If reservoir levels are lower than the historical average, the actual effects will be greater than the predicted effects. Attachment 1 describes the modeling efforts to quantify changes in reservoir storage, riverflows, and river temperatures. Qualitative methods used to assess recreation effects include consideration of potential effects on the availability, accessibility, and quality of recreation sites.

For each EWA action evaluated, the maximum amount of acre-feet that would potentially be transferred was analyzed. If there were no significant effects at this maximum amount, it is assumed that a transfer of less water would also produce no significant effects.

14.2.2 Significance Criteria

EWA actions would result in a potentially significant adverse effect on recreational resources if recreational opportunities at affected facilities were substantially reduced.

The criteria below are consistent with the CALFED Programmatic Environmental Impact Statement/Environmental Impact Report. An impact on a recreational resource was potentially significant if implementing an action would cause:

- Changes in reservoir water levels or river flows that result in a substantial reduction of recreational opportunities;
- Changes of river temperature that reduce recreational swimming, tubing, canoeing, kayaking, and rafting; or
- Changes in fish and wildlife populations that would reduce recreation opportunities.

Recreational opportunities at reservoirs are affected if reservoir levels decline such that boat ramps become unusable. Boat ramp usability is chosen as the limiting factor because it is a quantifiable measurement and lower reservoir levels would generally affect boat ramps prior to affecting other recreational activities (e.g., swimming or fishing). If boat ramps remain usable, it is assumed that there are sufficient water levels in the reservoir to sustain all other recreational activities. In those cases where boat ramp usability is not a good indicator of ability to use other recreational facilities, a qualitative discussion follows.

14.2.3 Environmental Consequences/Environmental Impacts of the No Action/No Project Alternative

The analysis of the recreational facilities during the assessment period (Stage 1 phase of CALFED) indicated that there would be no changes in recreational opportunities from that described in the affected environment section, with the exception of the completion of Diamond Valley Lake. Once completed, this reservoir would supply additional recreational opportunities above those described in the affected environment section. No other changes to recreation are anticipated, including construction of new facilities or the removal of existing facilities. The reliability of water supply would be as it was without the EWA. The potential for the CVP/SWP to receive less water, and as a result reservoirs in the Export Service Area to receive less water, would remain. Any effects on recreation of lowered reservoir levels would be the same in the future. Therefore, the No Action/No Project Alternative reflects the affected environment description and both are termed Baseline Condition in the following sections.

14.2.4 Environmental Consequences/Environmental Impacts of the Flexible Purchase Alternative

The Flexible Purchase Alternative allows transfers up to 600,000 acre-feet and does not specify transfer limits from the Upstream from the Delta Region or the Export Service Area. Transfers from the Upstream from the Delta Region would range from 50,000 to 600,000 acre-feet, limited by hydrologic year and conveyance capacity through the Delta. Although all potential transfers would not occur in one year, this

section discusses all transfers (a transfer amount that would result in greater than 600,000 acre-feet) to provide an effect analysis of a maximum transfer scenario. Similarly, the evaluation includes an analysis of up to 540,000 acre-feet in the Export Service Area to cover a maximum transfer scenario for that region.

14.2.4.1 Upstream from the Delta Region

14.2.4.1.1 Hunting and Fishing

EWA acquisition of water in the Upstream from the Delta Region could alter the locations of hunting areas. Rice fields that are flooded during the winter provide habitat for waterfowl and therefore are common hunting areas. If rice acreage is idled, waterfowl may be found on different fields than previous years; therefore, hunters would need to travel to different locations. As stated in Chapter 10, waterfowl populations would not decrease. Birds may flock to different fields, but the total number of birds and, therefore, the population from which to hunt from, would not decrease. Although hunting locations would change, hunting opportunities would stay the same; therefore, the effect on recreation from idling rice fields would be less than significant.

EWA acquisition of water would change reservoir levels and river flows, potentially affecting fishing opportunities. Fishing in reservoirs and rivers is a popular recreational activity. The timing, flow, and volume changes that would occur in reservoirs and rivers would not affect fish populations (see Chapter 9). Because the same number of fish would be present under the Flexible Purchase Alternative compared to the Baseline Condition, there would be no effects on recreational fishing opportunities due to a decrease in fish population.

14.2.4.1.2 Sacramento River

EWA acquisition of Sacramento River contractor water via groundwater substitution and crop idling would decrease Sacramento River flows from Lake Shasta downstream to the point of diversion in June[1]. EWA acquisition of up to 120,000 acre-feet of water via groundwater substitution and up to 158,000 acre-feet from crop idling would decrease Sacramento River flows by 1,160 cfs in June. The reduction from 18,180 cfs to 17,020 cfs in June would not affect rafting or boating, which have a minimum threshold of 5,000 cfs. Thus, the decrease in median monthly flows during June is less than significant.

EWA acquisition of Sacramento River contractor water via groundwater substitution and crop idling would change Sacramento River flows downstream from Lake Shasta in April through September. EWA acquisition of up to 120,000 acre-feet of water via groundwater substitution and up to 158,000 acre-feet from crop idling would increase Sacramento River flows by 240 cfs between Lake Shasta and the point of diversion in July. Flows in this reach would decrease 133 cfs and 111 cfs in August and September, respectively. Downstream from the diversion point, flows would increase by 289 cfs,

[1] Because of flow and temperature requirements in the Sacramento River, Lake Shasta would not be able to store EWA water from groundwater substitution and crop idling in April and May. During these months, flows in the Sacramento River would be the same as under the Baseline Condition. In some years, (depending on hydrologic conditions) Lake Shasta would store EWA water in June.

372 cfs, 429 cfs, 1,940 cfs, 777 cfs, and 157 cfs in April through September, respectively. This represents a 1 to 11 percent increase in flow. Such an incremental increase in flow is not associated with any reduction in recreational opportunities. The increases would not preclude any recreational activity (e.g., fishing, boating, or swimming) that occurred under the Baseline Condition. The flow increase would therefore have a less-than-significant effect on recreation along the Sacramento River.

The decrease in water released from Lake Shasta in June and the subsequent increase in water released July through September would not affect Sacramento River water temperature (see Table 14-4). Because there is no change in water temperature under the Flexible Purchase Alternative, there would be no temperature-related effect upon recreational users.

Table 14-4

[1] Based on 69 years modeled.

Lake Shasta

EWA acquisition of Sacramento River contractor water via groundwater substitution and crop idling would change the timing of releases from Lake Shasta. Lake Shasta would hold back at most 68,900 acre-feet that would have been released under the Baseline Condition. The lake level would decline faster in July and August compared to the Baseline Condition; however, end of month elevation in September would be the same as the Baseline Condition because of reduced releases during September (Figure 14-5). Lake Shasta elevation would be 1.1 feet lower in July, 0.5 of a foot lower in August, and equal to the Baseline Condition in September. The small change in elevation would not affect Bailey Cove boat ramp, which is available up to 50 feet of drawdown or Jones Valley and Centimudi, which are available up to 210 feet of drawdown. At Lake Shasta, low water levels affect campsites before boat ramps. Because the lake level decline is minimal however, access to campsites would not be adversely affected. The lower elevation in July and August would not adversely affect

recreational opportunities at the lake; therefore, the effect of this action would be less than significant.

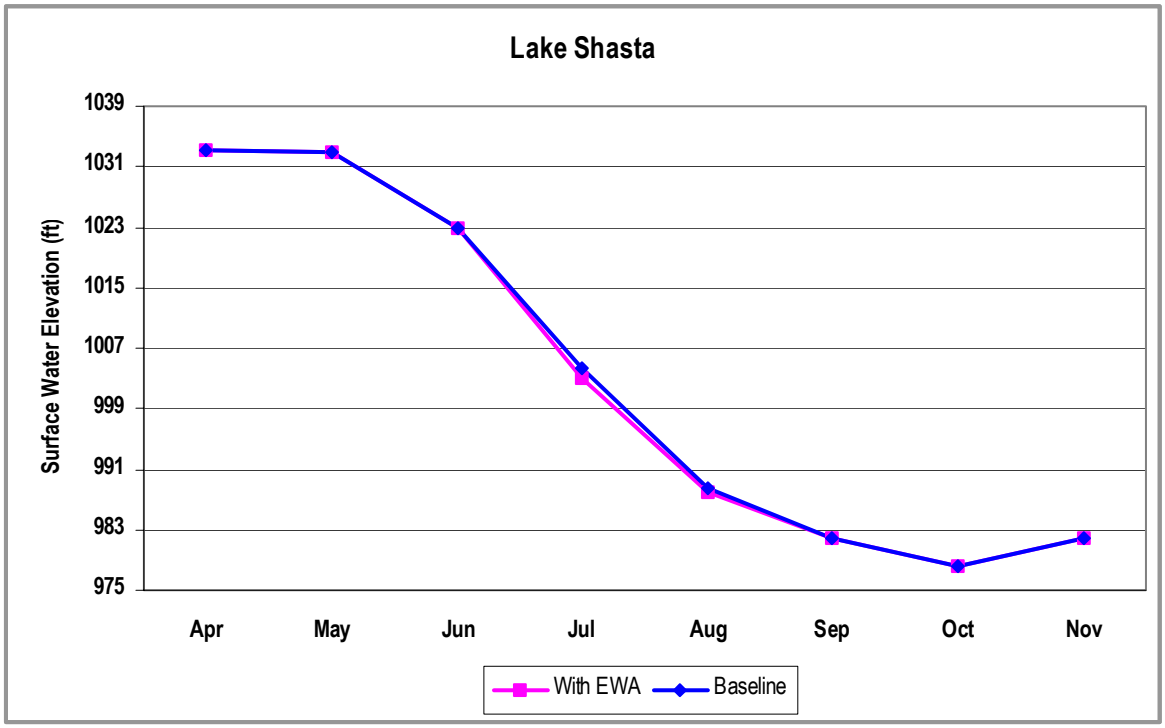

Figure 14-5
Changes in End of Month Surface Water Elevation in Lake Shasta

14.2.4.1.3 Feather River

EWA acquisition of water from Western Canal WD, Joint Water Districts, and Garden Highway MWC via crop idling and groundwater substitution would increase Feather River flows in July through September. In July through September, the Feather River would increase below the point of diversion by 2,105 cfs, 850 cfs, and 149 cfs in July, August, and September, respectively. This is an increase above the median monthly flow under the Baseline Condition of 36 percent, 19 percent, and 9 percent in July through September. The change in flow would not affect river temperature as shown in Table 14-5. The increase in flow because of increased releases is not associated with any reduction in recreational opportunities. The increases would not preclude any recreational activity (e.g., fishing, boating, or swimming) that occurred under the Baseline Condition. The flow increase would therefore have a less-than-significant effect on recreation along the Feather River.

EWA acquisition of Oroville-Wyandotte ID stored reservoir water would increase Feather River flows below Sly Creek and Little Grass Valley Reservoirs to Lake Oroville in November and December. The water released from Little Grass Valley and Sly Creek Reservoirs into Lake Oroville would not affect Feather River water temperature. Water released from the reservoirs would get diverted through Woodleaf and Forbestown tunnels to

run through the corresponding power generation facilities and end up in Ponderosa Reservoir. Transfer water spills from Ponderosa Reservoir directly into Lake Oroville. Because the water transferred from Little Grass Valley and Sly Creek Reservoirs into Lake Oroville would almost entirely bypass the Feather River, there would be no temperature effects on recreation.

[1] Based on 69 years modeled.

Little Grass Valley and Sly Creek

EWA acquisition of Oroville-Wyandotte ID stored reservoir water would decrease surface water elevations from December until refill for Sly Creek and Little Grass Valley Reservoirs. Little Grass Valley and Sly Creek Reservoirs are upstream from Lake Oroville on the Feather River. These reservoirs would release a combined maximum of 15,000 acre-feet of water from November to December. Figures 14-6 and 14-7 show historic reservoir surface water elevations and the potential change due to EWA actions. A release of a maximum of 12,000 acre-feet from Little Grass Valley would reduce storage by 23 percent, an elevation change of approximately 12 feet. Sly Creek Reservoir would release a maximum of 5,000 acre-feet. This reduction would cause a 17-foot decrease in reservoir elevation. These reductions would not affect activities such as boating and swimming because these activities have low uses during the winter months, the timeframe of the transfer. Other recreational activities such as hunting, hiking, sightseeing, fishing, and winter sports such as snowmobiling and cross-country skiing would not be affected adversely by a decrease in reservoir levels.

The reservoirs would be refilled with rain/snowmelt over the winter and into the spring. In most dry or critically dry water years, Little Grass Valley and Sly Creek Reservoirs refill during the winter and spring to levels sufficient for recreation. In some cases, the reservoir refills during critical years as well (for example, Little Grass Valley refilled in 1976, 1988, 1990-92, and 1994). Because the reservoirs have

historically refilled in most years, it is anticipated that the reservoirs would also refill after selling water to the EWA. In the critically dry years when reservoir levels are extremely low, recreation would be affected regardless of whether Oroville-Wyandotte ID has sold water to the EWA. Therefore, the EWA acquisition of Oroville-Wyandotte ID stored reservoir water and effects on Sly Creek and Little Grass Valley reservoirs would be less than significant.

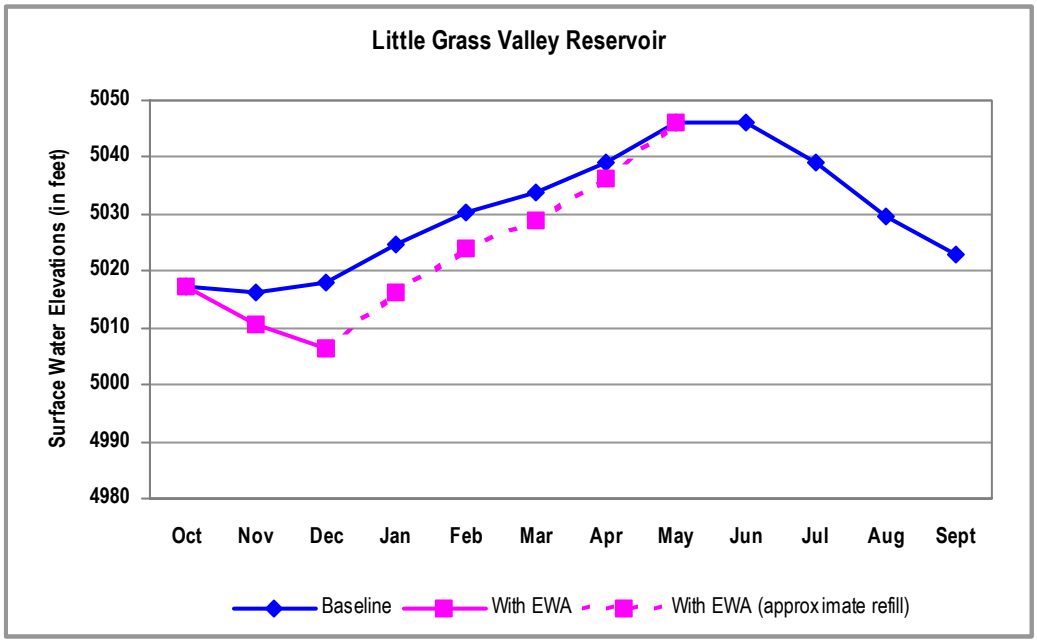

Figure 14-6
Changes in End of Month Surface Water Elevation in Little Grass Valley Reservoir

Note: It is anticipated that refill would occur as indicated in the above figure, depending on hydrologic conditions. However, if inflow were held by Little Grass Valley Reservoir at a time when the Delta was in balanced conditions, the water would be paid back to the Projects in a fashion similar to the original transfer.

According to the refill criteria (Section 4.2.3.1, Water Supply), Little Grass Valley and

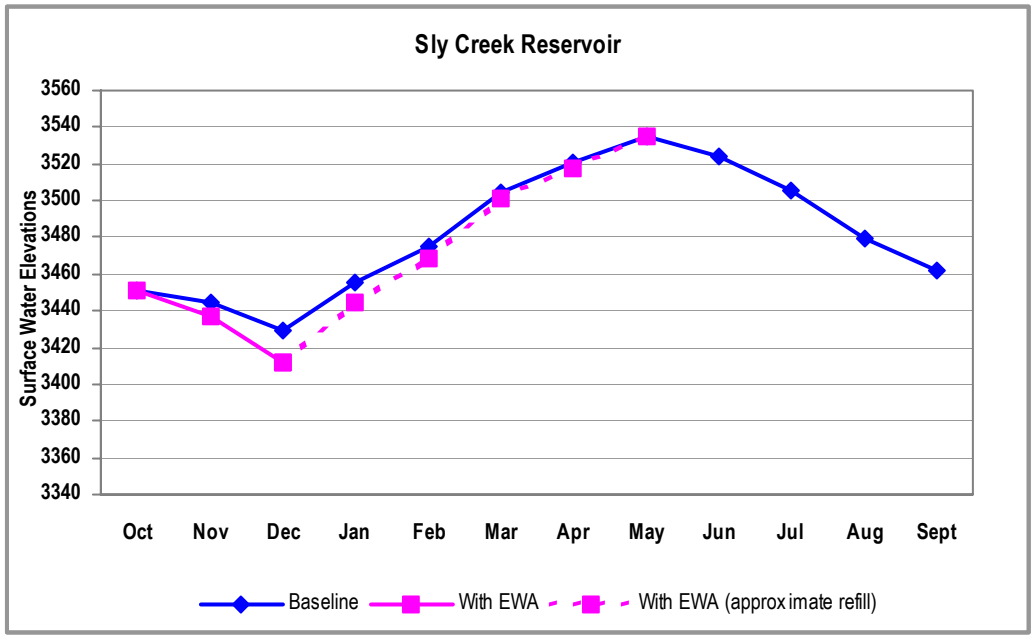

Figure 14-7
Changes in End of Month Surface Water Elevation in Sly Creek Reservoir

Note: It is anticipated that refill would occur as indicated in the above figure, depending on hydrologic conditions. However, if inflow were held by Sly Creek Reservoir at a time when the Delta was in balanced conditions, the water would be paid back to the Projects in a fashion similar to the original transfer.

Sly Creek Reservoirs would refill during the winter with runoff and snowmelt. If these reservoirs capture water while the Delta is not in excess conditions[2] (Section 4.1, Water Supply), the reservoirs will have to repay the water to the Projects the following summer. The water would be released on a similar schedule as the original EWA transfer and would have similar effects. The EWA agencies could enter into multi-year contracts with Oroville-Wyandotte ID, but would not purchase water a second year in a row if the reservoirs did not refill the previous year. The refill criteria are a part of the project; there would therefore be no significant effect on recreation.

Lake Oroville

EWA acquisition of water from Western Canal WD, Joint Water Districts, and Garden Highway MWC via crop idling and groundwater substitution would increase the surface water elevation April to June and decrease the surface water elevation in July and August in Lake Oroville compared to the Baseline Condition. EWA agencies would acquire 110,000 acre-feet through groundwater substitution and 126,550 acre-feet through

[2] Delta excess water conditions, also referred to as unbalanced conditions, are defined in the Coordinated Operation Agreement as "periods when it is agreed that releases from upstream reservoirs plus unregulated flow exceed Sacramento Valley in basin uses, plus exports."

crop idling. During April through June, Lake Oroville would hold back water that would have been released under the Baseline Condition. By the end of June, the surface water elevation in the reservoir would be, at most, 2 feet higher than under the Baseline Condition (Figure 14-8), resulting in a minor to modest positive effect on swimming and camping. Increased releases in July and August as the stored EWA water is released for cross-Delta transfer would cause the lake level to decline faster compared to the Baseline Condition; however, reduced releases in September would allow end of month elevation in September to be the same as the Baseline Condition. The small change in elevation would not affect the boat ramps, which are usable until the lake level falls below 700 msl. Low water levels affect boat-in campgrounds before boat ramps; however, the slight decrease in elevation (approximately 1.0 feet)

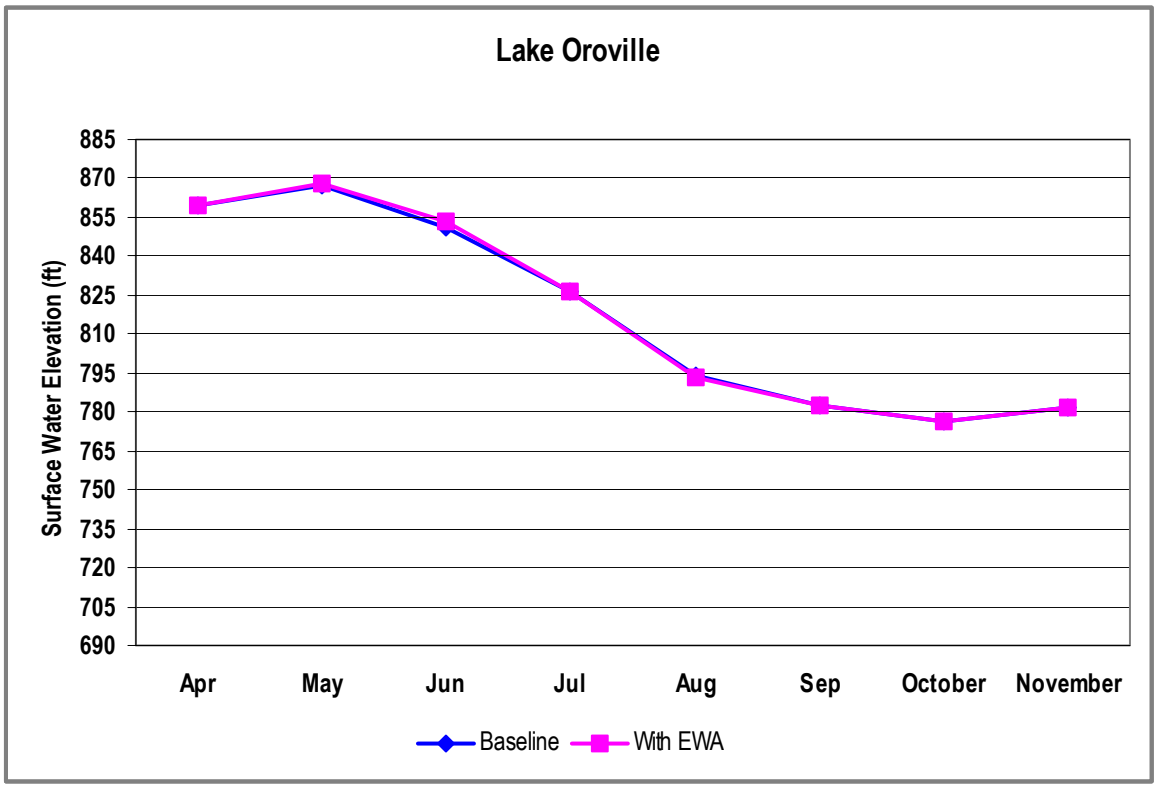

Figure 14-8
Changes in End of Month Surface Water Elevation in Lake Oroville

would not cause a decrease in use. The changes in surface water elevation would not affect fishing, swimming, and boating opportunities; therefore, the effects would be less than significant.

14.2.4.1.4 Yuba River

EWA acquisition of Yuba County WA water via groundwater substitution would decrease Yuba River flows from the power facility discharge upstream from Engelbright to the user's diversion points, typically at Englebright and Daguerre Point Dams from April to June. Yuba River flows would decrease at most by 239 cfs in late spring as farmers use groundwater for irrigation instead of surface water from New Bullards Bar Reservoir.

(A total of 12 to 19 percent reduction in April through June compared to the median flow under the Baseline Condition.) Because of limited river access, recreation is not common along the river. Fishing, however, does take place during this time of year. The decrease in flow would not affect fish population or decrease the quality of fishing. Fishing occurs year round when flows are less they would be with the EWA during April through June. The decrease in flows that would occur would not create a substantial loss of recreational opportunity; therefore, the effect would be less than significant.

EWA acquisition of Yuba County WA water via groundwater substitution and stored reservoir water would increase Yuba River flows downstream from Englebright July through September. Yuba River flows would increase at most by 1,005 cfs in July through September; approximately 60 percent above the Baseline Condition. The flow increase could affect recreational activities such as fishing. During July, August, and September, median flows are 1,791 cfs, 2,045 cfs, and 1,218 cfs, respectively. The flow increase of 1,005 cfs would increase river flows to levels that are fishable and that occur during other times of the year. For example, median flows in January through April are 2,405, 2,683, 3,177, and 2,022, respectively. These flows are comparable to flows that would occur with the EWA in July through September. Additionally, fishing reports indicate that the river is quite fishable at flows of 4,900 cfs and 5,500 cfs (substantially higher than flows with the EWA); however, wading should be undertaken cautiously (Bob's Fly Shack Fly Fishing Report 2003). The change in flow as a result of EWA actions would not increase flows beyond fishable levels. In fact, increased flow is beneficial to fish, which could lead to more favorable fishing conditions. The effect on recreation from increased flow would be less than significant.

Yuba River water temperatures would not be expected to fluctuate from the slower decrease of water from New Bullards Bar Reservoir in April through June. The release of stored reservoir water and groundwater substitution in July through September would decrease Yuba River water temperature. Changes in water temperatures were observed coincident with water transfers during 2001 (transfer of 172,000 acre-feet during July and August). For example, water temperatures at Highway 20 dropped from 73.4°F on July 3 to 62.6°F on July 8. Water temperatures at this site remained around 61°F until flows were reduced in late August, at which time the water temperatures increased with flow reduction. At the mouth of the Yuba River, water temperatures prior to the 2001 water transfers were approximately 73°F, compared to an average of 61°F after water transfers began. Although water temperatures would be substantially colder, recreational opportunities would not be substantially affected. The stretch of the Yuba River below Englebright is not a common recreation spot because of access limitations. The main recreational opportunities that exist are fishing, and swimming to a limited extent. The cooler water temperature is beneficial for fish, which could lead to more favorable fishing conditions. Recreational activities, including swimming, occur throughout the summer on the Sacramento and American Rivers, which have water temperatures ranging from 48°F to 66°F (see Sections 14.2.4.1.2 and 14.2.4.1.5). Yuba River water

temperature with the EWA would be within this range. Therefore, while the water temperature may not be as desirable as without the EWA, recreational users could partake in water dependent activities at lower river water temperatures as demonstrated by use of the American and Sacramento Rivers. The effect on recreation on the Yuba River from the purchase of stored reservoir water and groundwater substitution does not substantially affect recreational opportunities and would therefore be less than significant.

New Bullards Bar Reservoir

EWA acquisition of water from Yuba County Water Agency (Yuba County WA) via stored reservoir water and groundwater substitution would alter the surface water elevation April to refill at New Bullards Bar Reservoir. EWA agencies would acquire 85,000 acre-feet through groundwater substitution. During April through June, New Bullards Bar Reservoir would hold back water that would have been released under the Baseline Condition. By the end of June, the surface water elevation in the reservoir would be, at most, 5 feet higher than under the Baseline Condition (Figure 14-9). An increase in the surface water elevation would likely cause a net positive effect on recreational uses; fishing, swimming, and boating opportunities may be enhanced over the Baseline Condition.

Yuba County WA would not enter into a transfer agreement unless local needs, instream flows, and system demand requirements were met. If these elements were met, EWA agencies could acquire water during July through September. Releases from New Bullards Bar Reservoir would be, at a maximum, 100,000 acre-feet of water from stored reservoir water and 85,000 acre-feet from groundwater substitution. The combination of these releases would reduce lake levels compared to the Baseline Condition by 1 foot, 10 feet, and 24 feet in July, August, and September, respectively. This reduction would leave boat ramps operable into October. Dark Day boat ramp would become inoperable toward mid-October; Cottage Creek boat ramp would remain operable throughout the year. The water in New Bullards Bar Reservoir would decline below the end of the Dark Day boat ramp, but this would occur late in the recreational season. The number of boaters would be fewer than during the peak recreational season (Memorial Day through Labor Day) and the Cottage Creek boat ramp would still be operational; therefore, the recreational opportunity would not be substantially decreased.

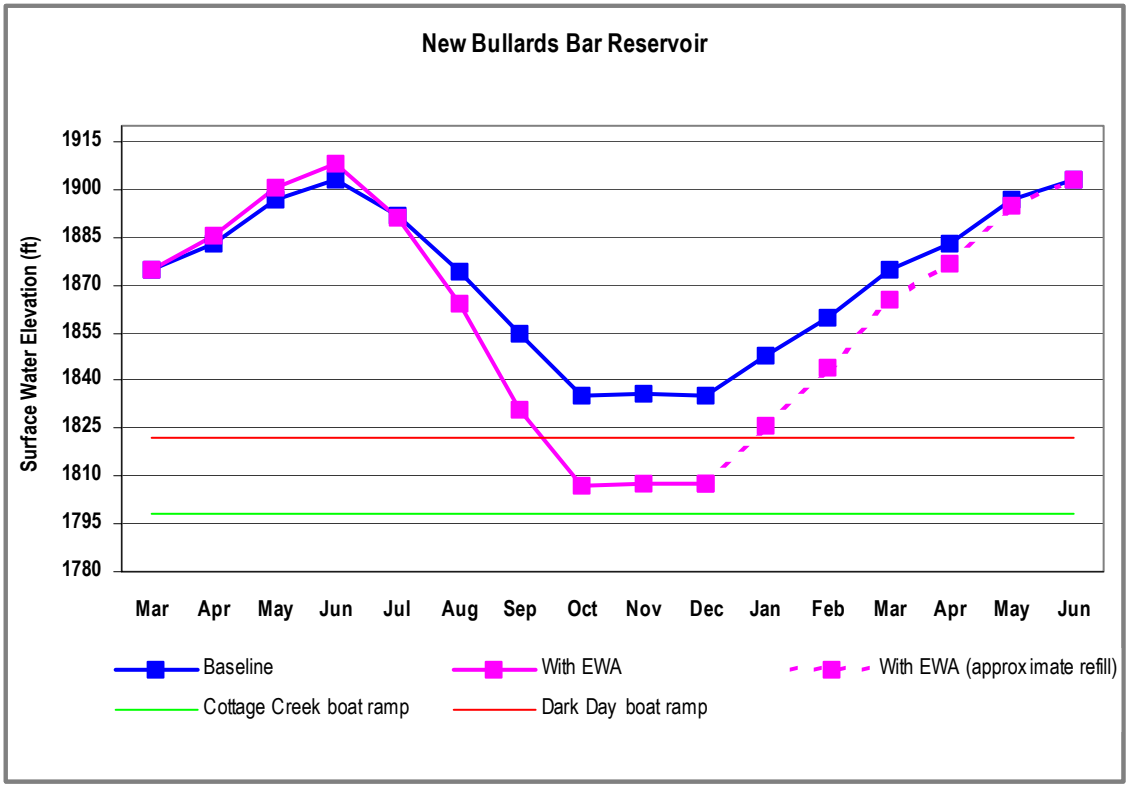

Figure 14-9
Changes in End of Month Surface Water Elevation in New Bullards Bar Reservoir

Note: It is anticipated that refill would occur as indicated in the above figure, depending on hydrologic conditions. However, if inflow were held by New Bullards Bar Reservoir at a time when the Delta was in balanced conditions, the water would be paid back to the Projects in a fashion similar to the original transfer.

Camping, also a popular activity at New Bullards Bar Reservoir, could be affected by a decrease in reservoir levels. Boat-in campgrounds become inaccessible as water levels recede, historically by mid-August (Chavez 2003). With the EWA, the boat-in campground would become inaccessible approximately 1 week earlier than the Baseline Condition because of lower water levels. While this is a decrease in recreational opportunity, it is not a substantial loss of opportunity. Additionally, camping (other than using the boat-in campground) is still available at campgrounds surrounding the reservoir. The overall effect on recreation from the purchase of stored reservoir water would be less than significant.

The EWA agencies and Yuba County WA could agree to transfer water under a multi-year contract. If full refill occurred, which it has for 85 percent of the past transfers, effects on recreation for subsequent years would be the same as described above. If full refill did not occur, Yuba County WA would consider selling less water the following year. The EWA agencies would not purchase water if the transfer would cause a significant effect on recreation.

14.2.4.1.5 American River

EWA acquisition of Placer County WA stored reservoir water would increase American River flows downstream from French Meadows Reservoir to Folsom Lake from June to October. Releases would increase relative to the Baseline Condition. Under the Baseline Condition, median flows downstream from Oxbow Power House on the Middle Fork[3] are 790 cfs, 793 cfs, and 776 cfs during June, July, and August, respectively. If flows increased during this time period, the releases would raise flow rates above the minimum-rafting threshold of 850 cfs, providing a beneficial effect on recreation resources.

EWA acquisition of Placer County WA stored reservoir water would decrease American River flows downstream from French Meadows Reservoir to Folsom Lake during refill of Hell Hole and French Meadows Reservoirs. River flows would decrease during the winter and early spring. During this time of year, recreational activities in and along the river are limited because of cold water and air temperatures. Hiking and wildlife viewing, common winter recreational activities, would not be adversely affected by a decrease in river flow. Fishing is not permitted in the river during winter through early spring. Thus, the EWA acquisition of Placer County WA stored reservoir water and the decrease in American River flows would be less than significant.

EWA acquisition of Sacramento Groundwater Authority's water via stored groundwater purchase would increase American River flows downstream from Folsom Lake from June through December. A relatively small increase in flow is not usually associated with any reductions in recreational opportunities. The increases would not be to such a level as to prevent recreational use of the river (e.g., rafting, swimming). The effect on recreational flows on the American River due to groundwater purchase would be less than significant.

The lower American River is a common recreation area for swimmers and rafters. A change in river temperature could affect the enjoyment of recreational users. Table 14-6 shows the average water temperature under the Baseline Condition as well as under the Flexible Purchase Alternative. There are no substantial differences in water temperature; therefore, the effect on recreation on the American River due to groundwater purchase would be less than significant.

[3] Releases from Hell Hole and French Meadows Reservoirs would flow through tunnels for power generation; increases to river flow would not occur until below Oxbow Power House.

Sep	65.9	66.1	0.2

[1] Based on 69 years modeled.

Hell Hole and French Meadows Reservoirs

EWA acquisition of Placer County WA stored reservoir water would decrease surface water elevations June to refill at Hell Hole and/or French Meadows Reservoirs. Hell Hole Reservoir and French Meadows Reservoir would release a combined maximum of 20,000 acre-feet of water. The amount released from each reservoir would be at the discretion of Placer County WA. This analysis assumes that 61 percent of the transfer amount would be released from Hell Hole, and the remainder would be released from French Meadows.

French Meadows would release 7,800 acre-feet beginning as early as June and ending as late as October. This analysis assumes that the water would be released between July and September. By the end of the release, the reservoir water surface elevation would drop approximately 8 feet. Figure 14-10 shows the historic reservoir storage, the potential change in storage with the EWA, and the boat ramp elevation at French Meadows Reservoir. EWA releases could cause Hell Hole Reservoir boat ramps to be out of the water (unusable) at the end of October, whereas the boat ramps would be usable through November under the Baseline Condition. Typically boating continues through October or early November (around the time of the first snowfall). Boating/fishing in small craft that could be hand carried to the water's edge would continue to be possible though also somewhat more difficult. Because low water levels affect boat ramps prior to other recreational uses, no other water-dependent activities at French Meadows Reservoir would be affected before the end of October.

Although the boat ramps would be unusable earlier with the EWA than under the Baseline Condition, recreational use of the boat ramps under the Baseline Condition would have stopped at approximately the same time because of weather conditions.

There is no substantial loss of recreational opportunity; therefore, the EWA acquisition of stored reservoir water and the decrease in surface water elevation at French Meadows Reservoir would be less than significant.

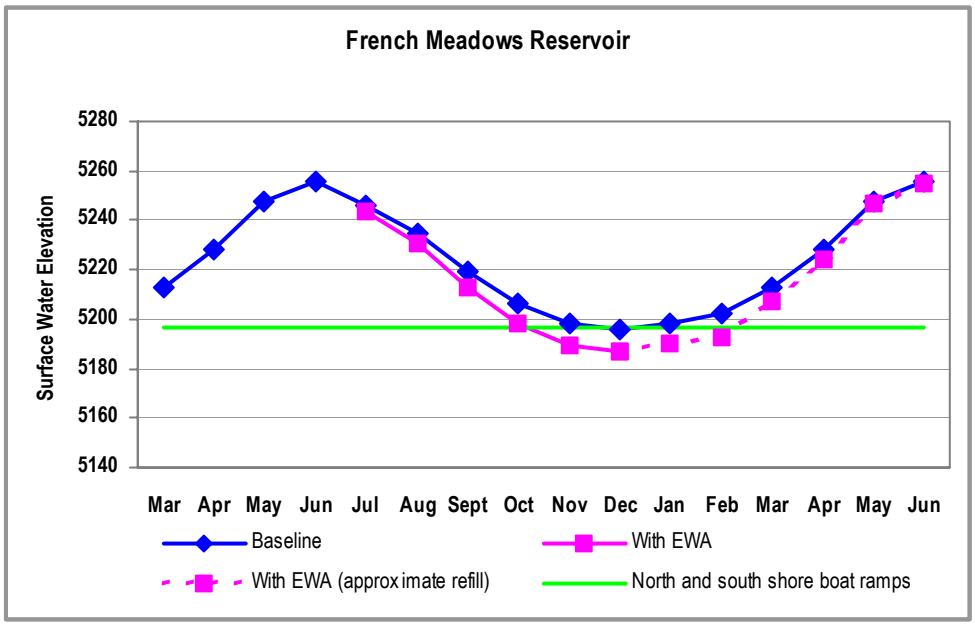

Figure 14-10
Changes in End of Month Surface Water Elevation in French Meadows Reservoir

Note: It is anticipated that refill would occur as indicated in the above figure, depending on hydrologic conditions. However, if inflow were held by French Meadows Reservoir at a time when the Delta was in balanced conditions, the water would be paid back to the Projects in a fashion similar to the original transfer.

Figure 14-11 shows the historic end-of-month storage at Hell Hole Reservoir and the end-of-month storage due to EWA actions during the transfer periods. The release of 12,200 acre-feet would reduce the water surface level by 14 feet. Camping and fishing are the major recreational activities on the reservoir, and these activities would not be significantly affected by a decrease in reservoir levels. As stated in Chapter 9, this change in reservoir level would not affect fish populations or the quality of fishing at the reservoir adversely. Historically, the boat ramp at Hell Hole Reservoir is unusable during winter because of low reservoir levels. Winter access would not change under the Flexible Purchase Alternative. Additionally, the boat ramp would remain usable during peak recreational months despite the decrease in reservoir levels. EWA releases could cause Hell Hole Reservoir boat ramps to be out of the water (unusable) at the end of October, whereas the boat ramps would be usable through November under the Baseline Condition. Typically boating continues through October or early November. After the first snowfall, access over the ridge becomes difficult. Boating/fishing in small craft that could be hand carried to the water's edge would continue to be possible though also somewhat more difficult. (Jue 2003) Therefore, although the boat ramps would be unusable earlier with the EWA than under the

Baseline Condition, recreational use of the boat ramps under the Baseline Condition would have stopped at approximately the same time because of weather conditions. There is no substantial loss of recreational opportunity; therefore, the EWA acquisition of stored reservoir water and the decrease in surface water elevation at Hell Hole Reservoir would be less than significant.

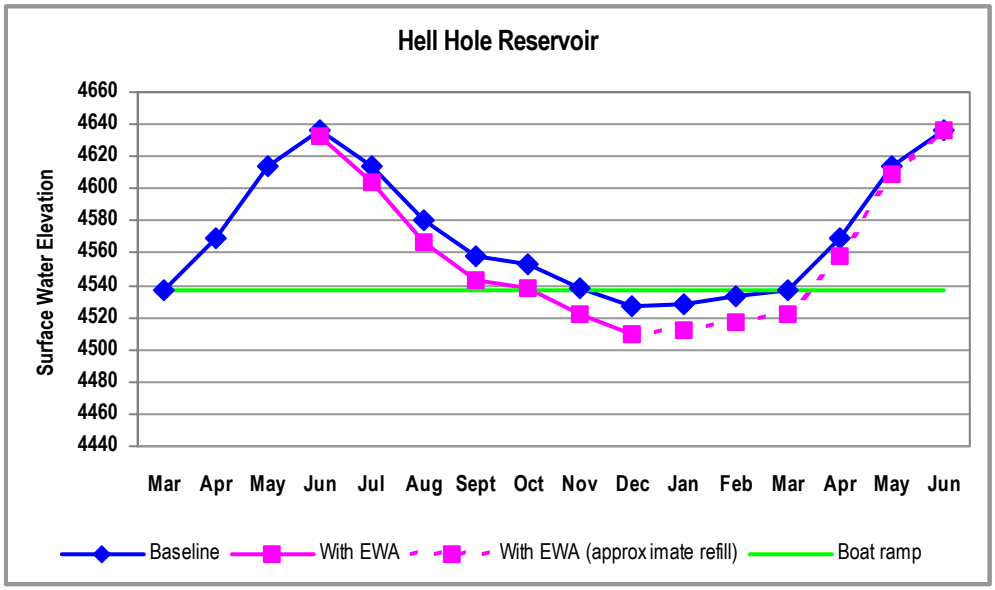

Figure 14-11
Changes in End of Month Surface Water Elevation in Hell Hole Reservoir

Note: It is anticipated that refill would occur as indicated in the above figure, depending on hydrologic conditions. However, if inflow were held by Hell Hole Reservoir at a time when the Delta was in balanced conditions, the water would be paid back to the Projects in a fashion similar to the original transfer.

According to the refill criteria (Section 4.2.3), Hell Hole and French Meadows Reservoirs would refill during the winter with runoff and snowmelt. If the reservoirs capture water while the Delta is not in excess conditions, water would be released and paid back to the Projects on a similar schedule as the original EWA transfer, and effects would be similar. If the EWA agencies acquired water through a multi-year contract with Placer County WA, water could be transferred during a second year, even if the reservoirs did not refill the year before, as long as the two reservoirs did not drop below a combined 50,000 acre-feet of storage (minimum operating levels). Thus, at a maximum, EWA actions could reduce storage at Hell Hole by 24,400 acre-feet (to 118,000 acre-feet) and at French Meadows by 15,600 acre-feet (to 67,000 acre-feet). This decrease in storage would be less than significant because the surface storage during peak recreation times would remain at or above minimum boat ramp operating levels.

Folsom Lake

EWA acquisition of Sacramento Groundwater Authority's water via stored groundwater purchase and Placer County Water Agency's water via stored reservoir water would change surface water elevations in Folsom Lake. During July and August, the surface water elevation at Folsom Lake would be 0.8 of a foot lower than the Baseline Condition. The lake level would decline faster in July and August compared to Baseline Condition; however, end of month elevation in September would be the same as the Baseline Condition because of reduced releases during September (Figure 14-12). The small change in elevation would not affect the boat ramps, which are usable until the lake level falls below 412 feet msl. Lower lake elevations affect boat ramps and other water-dependent activities simultaneously. Because low water levels do not significantly affect boat ramps, other water-dependent activities would also not be significantly affected.

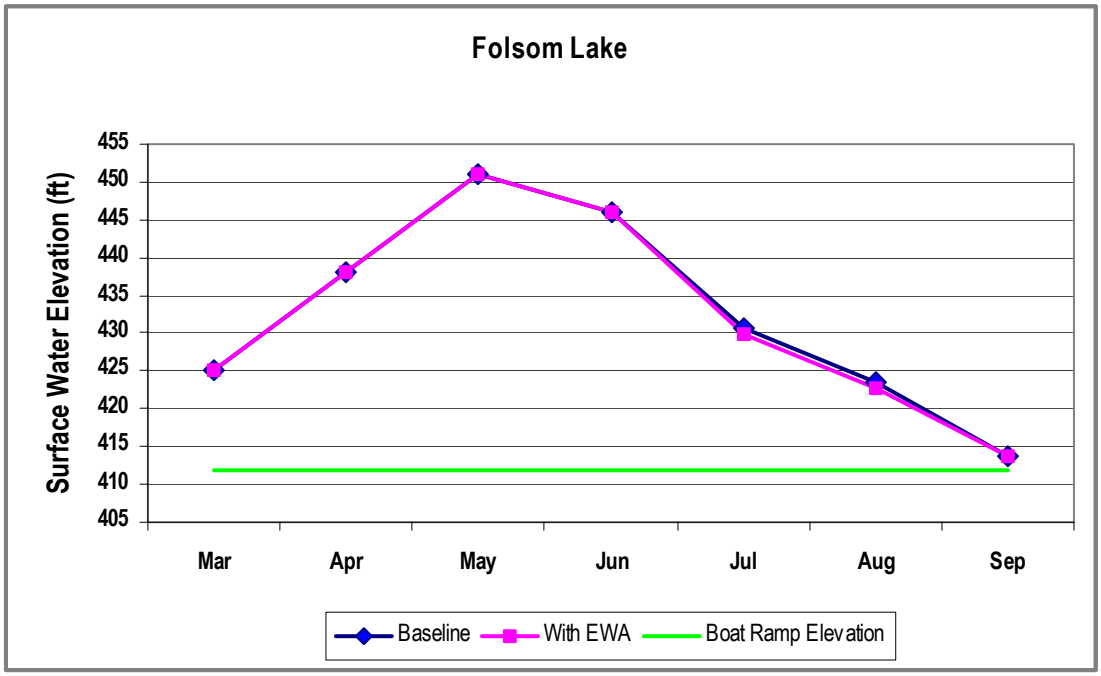

Figure 14-12
Change in End of Month Surface Water Elevation in Folsom Lake

14.2.4.1.6 Merced River

EWA acquisition of Merced ID water via groundwater substitution would decrease Merced River flows downstream from New Exchequer Dam to the point of diversion in April through June. Merced River flows in this reach would decrease by approximately 70 cfs (between 8 percent and 14 percent of monthly median flows). This reach of river has several dams and is not easily accessible for recreation. The recreational opportunities

that do exist on the river (e.g., fishing) would not be affected by the predicted decrease in flow. Flows with the EWA would be comparable to or higher than flows during the summer months under the Baseline Condition when the river is fishable. There would be no substantial loss of recreational opportunity on the Merced River as a result of groundwater substitution.

Lake McClure

EWA acquisition of Merced ID water via groundwater substitution would increase the water surface elevation in Lake McClure compared to the Baseline Condition. EWA agencies could acquire 25,000 acre-feet through groundwater substitution. During April through September, Lake McClure would hold back water that would have been released under the Baseline Condition. By the end of September, the surface water elevation in the reservoir would be, at most, 3 feet higher than the Baseline Condition (Figure 14-13). An increase in the surface water elevation would have a slightly beneficial effect on recreational uses; fishing, swimming, and boating opportunities would be slightly enhanced over the Baseline Condition. Under a multi-year transfer, effects on recreation from groundwater substitution would be same as described for a 1-year transfer.

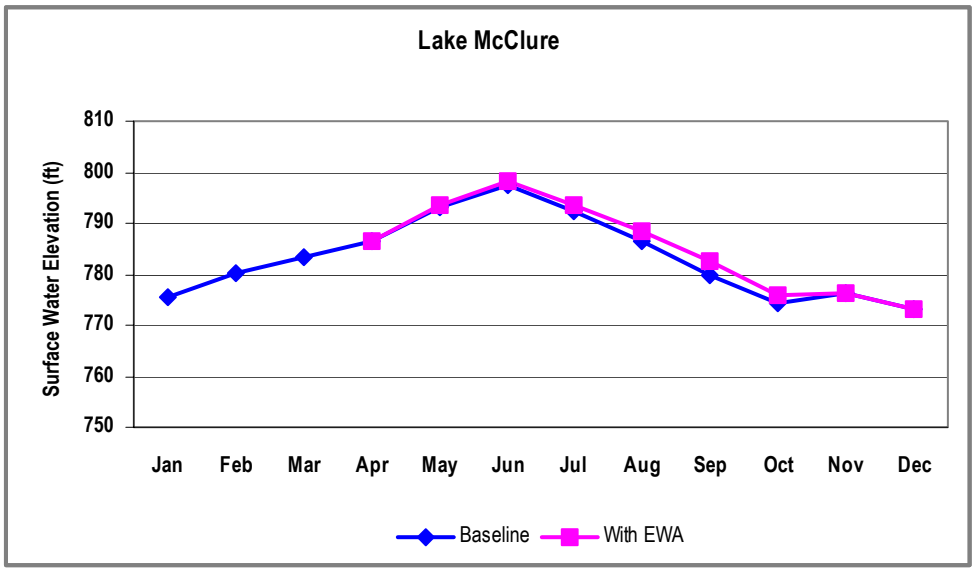

Figure 14-13
Changes in End of Month Surface Water Elevation in Lake McClure

14.2.4.2 Delta

There would be no decreases in Delta inflows from the Sacramento or San Joaquin Rivers under the Flexible Purchase Alternative. Because river water temperatures are not significantly affected in the Upstream from the Delta Region, there would be no adverse effect on recreation from changes in water temperature in the Delta. Therefore, no effects on recreation in the Delta would be anticipated.

14.2.4.3 Export Service Area

14.2.4.3.1 Anderson Reservoir

Source shifting at Anderson Reservoir would decrease the summer surface water elevation compared to the Baseline Condition. Anderson Reservoir would be used to compensate Santa Clara Valley Water District's delayed receipt of water from San Luis. A maximum of 20,000 acre-feet could be source shifted. Per District Resolution 605, the District would not draw down the reservoir below its minimum summer pool of 20,000 acre-feet, which is necessary to maintain recreational opportunities. Because the minimum storage would not be lowered with the EWA, there would be no significant effects on recreation.

14.2.4.3.2 San Luis Reservoir

Borrowing project water from San Luis Reservoir would decrease surface water elevations. Under the Baseline Condition, surface water elevations in San Luis Reservoir would begin to decrease in mid-April. At approximately 300,000 acre-feet, the "low-point problem" at San Luis Reservoir occurs, where warm-season algae growth and decreasing summer levels can affect the quality of the reservoir water and impair the ability of urban water agencies to treat the water adequately for municipal and industrial uses. EWA actions would be managed to prevent contributing to or aggravating the low point problem. (See Figure 2-13, Section 2.4.3.4.2.) Under the Baseline Condition, San Luis Reservoir is drawn down each summer; however, multi-stage boat ramps allow continued access to the reservoir during low water levels. Under the Flexible Purchase Alternative, there would be no significant change to recreational opportunities, including water-enhanced and water-based activities. Therefore, the effect of borrowing project water would be less than significant.

14.2.4.3.3 Lake Mathews, Lake Perris, Castaic Lake, and Diamond Valley Lake

Source shifting would decrease the summer surface water elevation of the targeted reservoirs. Metropolitan WD has many options for source shifting. These options include:

- **Lake Mathews, Lake Perris, Castaic Lake, and Diamond Valley Lake.** Metropolitan WD could delay delivery of SWP water and draw its supplies instead from these storage facilities and accept the SWP water deliveries at a later date.

- **Semitropic and Arvin Edison.** During wet years, Metropolitan WD could reduce deliveries when they would have otherwise delivered water to storage. Metropolitan WD could then deliver SWP water to Semitropic and Arvin Edison at a later date.

- **Hayfield (upstream aqueduct groundwater storage on the Colorado River).** Metropolitan WD could delay delivery of Colorado River water to Hayfield; the water would be delivered at a later date.

- **Change blend.** Metropolitan WD generally maximizes water sources and quality by blending Colorado River and SWP water 50:50. Metropolitan WD could change the blend to provide water for source shifting.

Lake Mathews
Because there is no public access to Lake Mathews and no recreational opportunities on the lake, there would be no effects on recreation.

Lake Perris and Castaic Lake
Metropolitan WD has rights to flexible storage in Castaic Lake and Lake Perris allowing the agency to borrow water from the lakes for up to 5 years, subject to DWR approval. The flexible storage in Castaic Lake is 153,940 acre-feet and 65,000 acre–feet in Lake Perris. The Monterey Agreement[4], signed in 1995, established these amounts of storage for Metropolitan WD. Metropolitan WD has exercised this storage several times, including in 2001 as part of the source shifting agreement in that year. The amount of water that could be source shifted under the EWA would fall within the recent operating parameters of both Castaic Lake and Lake Perris provided Lake Perris is not drawn more than 20,000 acre-feet below its full volume.

Operating within the limits of this flexible storage produces some adverse effects to recreation within the Baseline Condition. With the Flexible Purchase Alternative, however, effects on recreational facilities could occur more frequently compared to the Baseline Condition. Although no further drawdown of the reservoirs would occur beyond what is permitted as a part of the agency's flexible storage, the increased frequency of the drawdown would be a potentially significant impact. The mitigation measures listed in Section 14.2.7 would coordinate reservoir operations to reduce drawdown during peak recreational periods and therefore reduce the potentially significant impact to less than significant.

Diamond Valley Lake
At the development of this document, recreational facilities at Diamond Valley Lake were not complete; therefore, no analysis on the potential effects on those facilities is possible. Given the size of Diamond Valley, 800,000 acre-feet, the amount of water used for EWA assets would not likely have an adverse effect on recreation.

14.2.5 Environmental Consequences/Environmental Impacts of the Fixed Purchase Alternative

The Fixed Purchase Alternative specifies purchases of 35,000 acre-feet from the Upstream from the Delta Region, and 150,000 acre-feet from the Export Service Area. While the amounts in each region are fixed, the acquisition types and sources could vary. To allow the EWA Project Agencies maximum flexibility when negotiating purchases with willing sellers, this section analyzes the effects on each potential transfer. These transfers are the same actions as those described for the Flexible Purchase Alternative, but the amounts are limited by the total acquisition amount in each region (35,000 acre-feet from the Upstream from the Delta Region and 150,000 acre-feet from the Export Service Area).

[4] The Monterey Agreement, signed in 1994 by DWR and SWP water contractors, addresses water supply reliability problems, provides greater flexibility in water operations, and provides greater financial stability for SWP contractors.

14.2.5.1 Upstream from the Delta Region

14.2.5.1.1 Hunting and Fishing

EWA acquisition of water in the Upstream from the Delta Region could alter the locations of hunting areas. Rice fields that are flooded during the winter provide habitat for waterfowl and therefore are common hunting areas. If rice acreage is idled, waterfowl may be found on different fields than previous years; therefore, hunters would need to travel to different locations. As stated in Chapter 10, waterfowl populations would not decrease. Birds may flock to different fields, but the total number of birds and, therefore, the population from which to hunt from, would not decrease. Although hunting locations would change, hunting opportunities would stay the same; therefore, there would be no significant effect on recreation from idling rice fields.

EWA acquisition of water would change reservoir levels and river flows, potentially affecting fishing opportunities. Fishing in reservoirs and rivers is a popular recreational activity. The timing, flow, and volume changes that would occur in reservoirs and rivers would not affect fish populations (see Chapter 9). Because the same number of fish would be present under the Baseline Condition compared to with the EWA, there would be no significant effects on recreational fishing opportunities due to a decrease in fish population.

14.2.5.1.2 Sacramento River

EWA acquisition of Sacramento River contractor water via groundwater substitution and crop idling would decrease Sacramento River flows from Lake Shasta downstream to the point of diversion in June. EWA acquisition of up to 35,000 acre-feet of water via groundwater substitution or up to 35,000 acre-feet from crop idling would decrease monthly Sacramento River flows by 180 cfs in June. The reduction from 18,180 cfs to 18,000 cfs in June would not affect rafting or boating, which have a minimum threshold of 5,000 cfs. Thus, the decrease in median monthly flows during June would be less than significant.

Lake Shasta

The decrease in water released from Lake Shasta in June and the subsequent increase in water released July through August would not affect Sacramento River water temperature. (Table 14-4 shows changes in river temperature for the Flexible Purchase Alternative. Because there is no change in temperature under larger transfer amounts, there would be no temperature change for lesser transfer amounts under the Fixed Purchase Alternative.) Because there is no change in water temperature under the Fixed Purchase Alternative, there would be no effect to recreational users due to an increase or decrease in water temperature; the effect would be less than significant.

14.2.5.1.3 Feather River

EWA acquisition of water from Western Canal WD, Joint Water Districts, and Garden Highway MWC via crop idling and groundwater substitution would increase Feather River flows in July through September. A maximum of an additional 35,000 acre-feet would be released from Lake Oroville, which would increase flows on the Feather River below

the Thermalito Afterbay. The effects of these EWA actions are evaluated in Section 14.2.4.1.3, Feather River for the Flexible Purchase Alternative. The increase in flow on the Feather River would be greater under the Flexible Purchase Alternative than under the Fixed Purchase Alternative. There are no significant effects on recreation under the Flexible Purchase Alternative; therefore, there would no be significant effects on recreation under the Fixed Purchase Alternative.

EWA acquisition of Oroville-Wyandotte ID stored reservoir water would increase Feather River flows below Sly Creek and Little Grass Valley Reservoirs to Lake Oroville in November and December. The same amount of water could be transferred under the Fixed Purchase Alternative as described in the Flexible Purchase Alternative. Refer to Section 14.2.4.1.3, Feather River, for a discussion of potential effects. The effects of the Flexible Purchase Alternative are less than significant; the effects of the Fixed Purchase Alternative would also be less than significant.

Sly Creek and Little Grass Valley Reservoirs

EWA acquisition of Oroville-Wyandotte Irrigation District (Oroville-Wyandotte ID) stored reservoir water would decrease surface water elevations December until refill for Sly Creek and Little Grass Valley Reservoirs. Little Grass Valley and Sly Creek Reservoirs are upstream from Lake Oroville on the Feather River. These reservoirs would release a combined maximum of 15,000 acre-feet of water from November to December. Figures 14-6 and 14-7 show historic reservoir surface water elevations and the potential change due to EWA actions. The same amount of water could be transferred under the Fixed Purchase Alternative as described in the Flexible Purchase Alternative. Refer to Section 14.2.4.1.3, Feather River, for a discussion of potential effects. The effects of the Flexible Purchase Alternative would be less than significant; the effects of the Fixed Purchase Alternative would also be less than significant.

Lake Oroville

EWA acquisition of water from Western Canal WD, Joint Water Districts, and Garden Highway MWC via crop idling and groundwater substitution would increase the surface water elevation April to June and decrease the surface water elevation in July and August in Lake Oroville compared to the Baseline Condition. EWA could acquire up to 35,000 acre-feet of water via groundwater substitution or up to 35,000 acre-feet from crop idling. Effects on Lake Oroville recreation from an increase (April through June) and decrease (July and August) in surface water elevation are evaluated in Section 14.2.4.1.3, Feather River for the Flexible Purchase Alternative. There would be less change in surface water elevation under the Fixed Purchase Alternative than under the Flexible Purchase Alternative. Because there were no significant effects under the Flexible Purchase Alternative, there would also be no significant effects under the Fixed Purchase Alternative.

14.2.5.1.4 Yuba River

EWA acquisition of Yuba County WA water via groundwater substitution would decrease Yuba River flows from April to June. Yuba River flows would decrease by 195 cfs in late

spring as farmers use groundwater for irrigation instead of surface water from New Bullards Bar Reservoir. Because of limited river access, recreation use is not common along the river. The slight decreases in flows (10 to 16 percent of the median monthly flow) that would occur would not adversely affect the few recreational users.

Yuba River water temperatures would not be expected to fluctuate from the slower release of water from New Bullards Bar Reservoir in April through June. In July through September, an additional release (195 cfs) would be released from New Bullards Bar Reservoir. The increased release could lower river temperature. The effects described in Section 14.2.4.1.4, Yuba River, under the Flexible Purchase Alternative analyzed effects on river temperature for a greater release. Because there were no significant effects under the Flexible Purchase Alternative, there would be no significant effects on recreation because of changes in river temperature under the Fixed Purchase Alternative.

New Bullards Bar Reservoir

EWA acquisition of Yuba County Water Agency (Yuba County WA) stored reservoir water would decrease surface water elevations July to refill at New Bullards Bar Reservoir. New Bullards Bar Reservoir would release, at a maximum, 35,000 acre-feet of water to be used as an EWA asset. Yuba County WA would not enter into a transfer agreement unless local needs, instream flows, and system demand requirements were met. If these elements were met, EWA agencies could acquire up to 35,000 acre-feet, decreasing the reservoir elevation 8 feet by September, from 1,855 msl to 1,847 feet msl. The Dark Day and Cottage Creek boat ramps would remain usable at this elevation; therefore, there would be no significant effects on recreation.

14.2.5.1.5 American River

EWA acquisition of Placer County WA stored reservoir water would increase American River flows downstream from French Meadows Reservoir to Folsom Lake from June to October. The same amount of water could be transferred under the Fixed Purchase Alternative as described in the Flexible Purchase Alternative. Refer to Section 14.2.4.1.5, American River, for a discussion of potential effects. The effects of the Flexible Purchase Alternative are beneficial; the effects of the Fixed Purchase Alternative are also beneficial.

EWA acquisition of Placer County WA stored reservoir water would decrease American River flows downstream from French Meadows Reservoir to Folsom Lake during refill of Hell Hole and French Meadows Reservoirs. The same amount of water could be transferred under the Fixed Purchase Alternative as described in the Flexible Purchase Alternative. Refer to Section 14.2.4.1.5, American River, for a discussion of potential effects. The effects of the Flexible Purchase Alternative would be less than significant; the effects of the Fixed Purchase Alternative would also be less than significant.

EWA acquisition of Sacramento Groundwater Authority's water via stored groundwater purchase would increase American River flows downstream from Folsom Lake from June through December. The same amount of water could be transferred under the Fixed

Purchase Alternative as described in the Flexible Purchase Alternative. Refer to Section 14.2.4.1.5, American River, for a discussion of potential effects. The effects of the Flexible Purchase Alternative were less than significant; the effects of the Fixed Purchase Alternative would also be less than significant.

The lower American River is a common recreation area for swimmers and rafters. A change in river temperature could affect the enjoyment of recreational users. Table 14-5 shows the average water temperature under the Baseline Condition as well as under the Flexible Purchase Alternative. Because the amount of water transferred under the Flexible Purchase Alternative is the same as under the Fixed Purchase Alternative, the table is accurate for the Fixed Purchase Alternative as well. There would be no substantial differences in water temperature; therefore, the effect on recreation on the American River due to groundwater purchase would be less than significant.

Hell Hole and French Meadows Reservoirs
EWA acquisition of Placer County WA stored reservoir water would decrease surface water elevations June to refill at Hell Hole and/or French Meadows Reservoirs. Hell Hole Reservoir and French Meadows Reservoir would release a combined maximum of 20,000 acre-feet of water. An equivalent amount of water could be sold to the EWA agencies under the Fixed Purchase Alternative, as is described under the Flexible Purchase Alternative. Refer to Section 14.2.4.1.5, American River, for a discussion of potential effects. The effects of the Flexible Purchase Alternative were less than significant; the effects of the Fixed Purchase Alternative would also be less than significant.

14.2.5.1.6 Merced River

EWA acquisition of Merced ID water via groundwater substitution would decrease Merced River flows downstream from New Exchequer Dam to the point of diversion in April through June. Merced River flows would decrease by approximately 70 cfs. An equivalent amount of water could be sold to the EWA agencies under the Fixed Purchase Alternative, as is described under the Flexible Purchase Alternative. Refer to Section 14.2.4.1.6, Merced River, for a discussion of potential effects. The effects of the Flexible Purchase Alternative were less than significant; the effects of the Fixed Purchase Alternative would also be less than significant.

Lake McClure
EWA acquisition of Merced ID water via groundwater substitution would increase the water surface elevation in Lake McClure compared to the Baseline Condition. EWA agencies could acquire 25,000 acre-feet through groundwater substitution. As shown in Figure 14-11, water levels in Lake McClure would only increase. An increase in surface water elevation would have a less-than-significant effect on recreational use.

14.2.5.2 Delta

There would be no decreases in Delta inflows from the Sacramento or San Joaquin rivers under the Fixed Purchase Alternative. Because river water temperatures are

not significantly affected in the Upstream from the Delta Region, there would be no adverse effect on recreation from changes in water temperature in the Delta. Therefore, the effects on recreation in the Delta would be less than significant.

14.2.5.3 Export Service Area

14.2.5.3.1 Anderson Reservoir

Source shifting at Anderson Reservoir would decrease the summer surface water elevation compared to the Baseline Condition. Anderson Reservoir would be used to compensate Santa Clara Valley Water District's delayed receipt of water from San Luis. A maximum of 20,000 acre-feet could be source shifted. An equivalent amount of water could be sold to the EWA agencies under the Fixed Purchase Alternative, as is described under the Flexible Purchase Alternative. Refer to Section 14.2.4.3.1, Anderson Reservoir, for a discussion of potential effects. The effects of the Flexible Purchase Alternative were less than significant; the effects of the Fixed Purchase Alternative would also be less than significant.

14.2.5.3.2 Lake Mathews, Lake Perris, Castaic Lake, and Diamond Valley Lake

Source shifting would decrease the summer surface water elevation of the targeted reservoirs. Source shifting options by Metropolitan WD would be the same under the Fixed Purchase Alternative as those described under the Flexible Purchase Alternative. Metropolitan WD could source shift a maximum of 200,000 acre-feet using the options described in Section 14.2.4.3.2. The effects stated in Section 14.2.4.3.2 would be the same for the Fixed Purchase Alternative. The potentially significant impact would be reduced to less than significant with the implementation of the mitigation measures listed in Section 14.2.7.

Borrowing project water from San Luis Reservoir would decrease surface water elevations. Under the Baseline Condition, surface water elevations in San Luis Reservoir would begin to decrease in mid-April. At approximately 300,000 acre-feet, the low-point problem at San Luis Reservoir occurs, whereby warm-season algae growth and decreasing summer levels can affect the quality of the reservoir water and impair the ability of urban water agencies to treat the water adequately for municipal and industrial uses. EWA actions would be managed to prevent contributing to or aggravating the low point problem. (See Figure 2-13, Section 2.4.3.4.2.) Under the Baseline Condition, San Luis Reservoir is drawn down each summer; however, multi-stage boat ramps allow continued access to the reservoir during low water levels. Under the Fixed Purchase Alternative, there would be no change to recreational opportunities, including water-enhanced and water-based activities. Therefore, the effect of borrowing project water would be less than significant.

14.2.6 Comparative Analysis of Alternatives

This chapter has thus far analyzed the effects of many potential transfers, looking at the "worst-case scenario" that would occur if all acquisitions happened in the same year. This approach ensures that all effects of transfers are included and provides the EWA Project Agencies the flexibility to choose transfers that may be preferable in a given year. The EWA, however, would not actually purchase all of this water in the

same year. This section provides information about how EWA would more likely operate in different year types. A further comparison of the alternatives is listed in Table 14-7.

In the Upstream from the Delta Region, recreational opportunities under the No-Project Alternative would be affected by year type. During wet years, increased precipitation and runoff would cause water surface elevations in reservoirs to be higher, which is beneficial for recreation. Dry years would produce limited inflow, which could cause boat ramps, campgrounds, and beaches to become inaccessible. Effects would be the same in the Export Service Area.

The Fixed Purchase Alternative would be limited to a maximum acquisition of 35,000 acre-feet from all sources of water. This amount could typically be obtained from stored reservoir water purchases in most year types. In very dry years, stored reservoir water may not be available, and the EWA would need to look to other sources. However, because water acquisitions would most likely be from stored reservoir water, the effects from the transfers described in this Draft EIS/EIR for recreation resources most likely would occur each year.

The Flexible Purchase Alternative could involve the purchase of up to 600,000 acre-feet of water from all sources in the Upstream from the Delta Region. EWA agencies would prefer to purchase water from upstream sources because the water is generally less expensive. The amount that could be purchased would be limited by the capacity of the Delta export pumps to move the water to the Export Service Area. During wet years, excess pump capacity may be limited to as little as 50,000 to 60,000 acre-feet of EWA asset water because the pumps primarily would be used to export Project water to Export Service Area users. Effects during wet years would therefore be close to those described under the Fixed Purchase Alternative. During dry years, when there would be less Project water available for pumping (and therefore the pumps would have greater availability capacity), the EWA Project Agencies could acquire up to 600,000 acre-feet of water from sources in the Upstream from the Delta Region.

The EWA Project Agencies usually prefer to purchase stored reservoir water because it is the least expensive option. In dry years, they would likely purchase all stored reservoir water available, and then look to other options for the remainder of their purchases. Therefore, the effects during dry years would be similar to those described in this Draft EIS/EIR. The effects on recreational resources, even under a maximum purchase scenario, were determined to be less than significant. In wet years, a portion of the stored reservoir water available would likely provide the entire amount of water that could be moved through the Delta.

The EWA agencies could manage water through source shifting in the Export Service Area under the Flexible Purchase and Fixed Purchase Alternatives. Source shifting is not dependent on water year type, but is related to demand on San Luis Reservoir. The EWA agencies would implement source shifting more frequently under the Fixed Purchase Alternative than under the Flexible Purchase Alternative, which would

draw down the reservoirs more often. Mitigation measures would reduce the potential effects for both alternatives.

Table 14-7
Comparison of the Effects of the Flexible and Fixed Purchase Alternatives on Recreation Resources

14.2.7 Mitigation Measures

The following mitigation measures will be implemented for potential effects caused by source shifting at Lake Perris and Castaic Lake:

- Water storage will be maximized to the extent possible during peak recreation use periods, especially summer months; and

- For Lake Perris, the EWA agencies would include in source shifting contracts with Metropolitan WD a limitation on the amount of flexible storage that can be drawn from that source. The limit would be determined with input from officials at Lake Perris Recreation Area. For Castaic Lake, the input from recreation officials should be considered so that ongoing planning and management of the recreation facilities can be coordinated with reservoir operations. Once schedules are known,

recreation area operators should be notified as soon as possible, in order to maximize management efforts.

14.2.8 Potentially Significant Unavoidable Impacts

There are no potentially significant unavoidable impacts.

14.2.9 Cumulative Effects

14.2.9.1 Upstream from the Delta Region

The Sacramento Valley Water Management Agreement, Dry Year Purchase Program, Drought Risk Reduction Investment Program, CVPIA Water Acquisition Program, and Environmental Water Program include water acquisitions upstream from the Delta. These programs all include stored reservoir water, and many include other acquisition types such as groundwater substitution, groundwater purchase, and crop idling. These programs, in addition to the EWA, could magnify the effects described in Sections 14.2.4.1 - 14.2.4.3.

The Environmental Water Program would purchase water from different facilities than the EWA. Therefore, there is no potential for a cumulative decrease in surface water elevation in reservoirs resulting in a reduction of recreational opportunities. The Sacramento Valley Water Management Agreement, Dry Year Purchase Program, and Drought Risk Reduction Investment Program, as well as other potential water transfers, could purchase water from the same reservoirs as the EWA. Other programs in combination with the EWA that purchase water from the same agency could draw down reservoirs further than analyzed in this chapter. The additional water sold for other programs would reduce the Baseline Condition as described and could cause significant cumulative effects. A cumulative effect would only be significant if the combined actions were greater than the significance criteria (reduced recreational opportunities caused by a loss of boat ramps, reduction in fish or waterfowl populations, or decrease in river temperature). Therefore, although the EWA could contribute to a cumulative effect (e.g., a greater reduction in reservoir elevation), the EWA would not purchase water from an agency if the purchase would cause a cumulatively significant effect on recreation.

Actions such as groundwater substitution and crop idling in the Upstream from the Delta Region would potentially occur in four out of the five cumulative programs. These actions, in addition to the EWA, would create changes in the timing and quantity of water released from reservoirs, altering river flows. Water transfers from other agencies along the same rivers as in the EWA program area would also cause a cumulative effect on the change in river flow. The cumulative effect is not anticipated to cause a significant effect on recreation because recreational uses of the rivers, including fishing, swimming, and rafting, are possible within large fluctuations in flow. It is not anticipated that the river flow would change to such a level as to cause a cumulatively significant effect on recreation.

14.2.9.2 Export Service Area

Only the Drought Risk Reduction Investment Program and the CVPIA Water Acquisition Program operate in the Export Service Area. Effects from crop idling in this area are not associated with any decreases in recreational opportunity. Therefore, increased crop idling from various programs would not produce a cumulatively significant effect.

Chapter 15
Flood Control

Floods can be very damaging and costly. In order to lessen the effects, numerous practices aim to reduce flood damages. The construction of levees, dams, and reservoirs are common methods of flood damage reduction in California. Levees confine the water flows within a channel. The integrity of a levee and its maximum design flow capacity, dictate the extent of a levee's effectiveness. Dams and reservoirs can be operated to reduce flows downstream by storing inflows and controlling releases.

Many agencies have a role in designing, constructing, and operating flood control facilities, such as the U.S. Bureau of Reclamation (Reclamation), the U.S. Army Corps of Engineers (USACE), the California Department of Water Resources (DWR), and the State Reclamation Board. The Federal Emergency Management Agency oversees the National Flood Insurance Program, which helps ensure protection from flood-related damages through the implementation of 3 main components: flood insurance program, floodplain management, and flood hazard mapping.

This chapter discusses the effects of the Flexible Purchase and Fixed Purchase Alternatives on flood control. Section 15.1 presents the affected environment/existing conditions and Section 15.2 evaluates the No Action, Flexible Purchase, and Fixed Purchase Alternatives, and a comparative analysis of the alternatives.

15.1 Affected Environment/Existing Conditions

This section describes the existing conditions in the study area. These conditions are current to 2003, where possible; otherwise, the latest available data have been used. This information serves as the reference conditions against which to compare program-induced effects.

15.1.1 Area of Analysis

Effects are assessed in the Upstream from the Delta Region, Delta Region, and in the Export Service Area. (See Figure 15-1.)

- **Upstream from the Delta Region**: Lake Shasta; Little Grass Valley and Sly Creek Reservoirs; Lake Oroville; New Bullards Bar Reservoir; French Meadows and Hell Hole Reservoirs; Folsom Lake; Lake McClure; Sacramento, Feather, Yuba, American, and Merced Rivers.

- **Delta Region**

- **Export Service Area**: Anderson Reservoir; Lake Perris; Castaic Lake; Diamond Valley Lake; California Aqueduct; and Tulare Lake Basin.

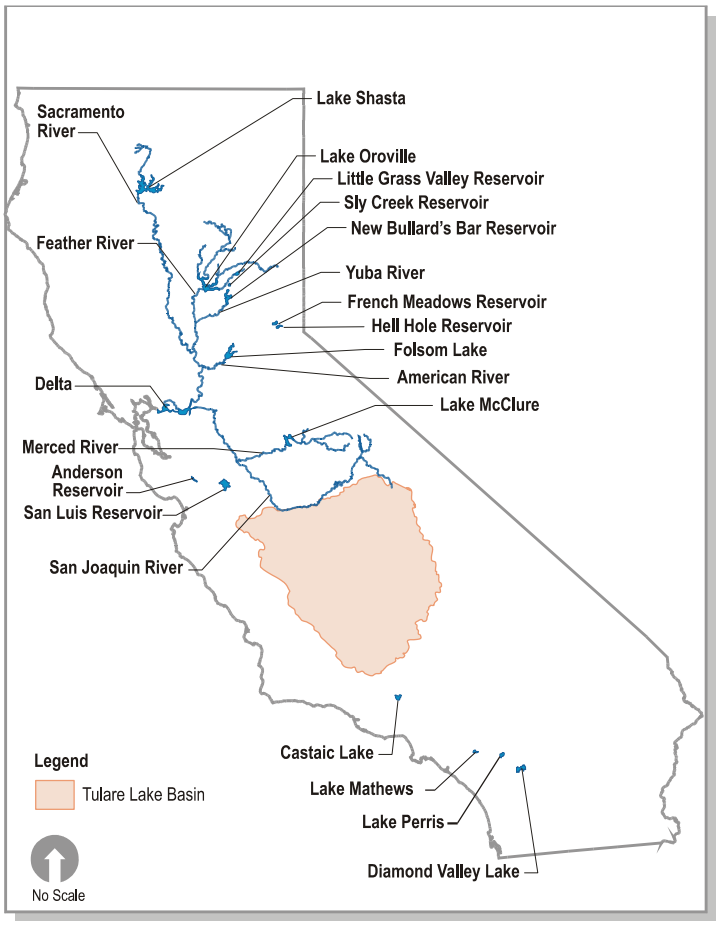

Figure 15-1
Flood Control Area of Analysis

15.1.2 Upstream from the Delta Region

In the Upstream from the Delta Region, a variety of infrastructure provides flood protection along the Sacramento and San Joaquin Rivers and their tributaries including the Yuba, Feather, American, and Merced rivers.

15.1.2.1 Reservoirs

Multi-purpose reservoirs and a system of weirs and bypasses contribute to the flood control system in the Upstream from the Delta Region by storing or diverting water around urban areas during periods of high runoff, thereby reducing the ultimate load placed on the levee system during floods. Very high inflows can reduce the ability of reservoirs to provide flood control. The amount of storage held in a reservoir at any point in time (conservation storage) is governed by the USACE criteria stated in flood control project's water control manual. Top of conservation storage can vary depending on time of year, upstream storage, and the type of storm (rain or snow) that is occurring. Top of conservation storage for each flood control project is also defined in each project's water control manual. The space between the top of conservation storage and the capacity of the reservoir is the required flood control space. This amount varies by flood control project. (The Resources Agency 1999)

15.1.2.2 Levees

Levees also provide flood control in the region. DWR defines warning stage for leveed rivers or channels as, "the stage at which patrol of flood control project levees becomes mandatory, or the stage at which flow occurs into bypass areas from project overflow weirs." Flood stage is defined in the DWR Flood Emergency Operations Manual as, "the stage at which the flow in a flood control project is at maximum design capacity." (The Resources Agency 1999).

Levee stability can be compromised because of any of the following (The Resources Agency 1997):

- **Overtopping:** Floodwater entering the channel is greater than its capacity, and water pours over the top of the levee.
- **Seepage and Piping:** Floodwater seeps through or under a levee and carries levee or foundation material with it. Some seepage through an earthen levee is common; however, if water creates a drainage path, or "pipe" through erodible material, material is gradually washed out through a "boil" on the landside of the levee.
- **Erosion:** High water velocity or wave action removes material from the levee or the streambank adjacent to the levee, leading to slope instability and increased seepage.
- **Sliding:** Seepage through the levee weakens the levee and/or foundation material to the point where the weight of soil exceeds the levee's internal strength and the levee slope slides.
- **Sloughing:** Seepage through the levee causes the outermost soil on the levee slope to slide down. Progressive sloughing causes increasingly heavy seepage until the levee gives way.

15.1.2.3 Sacramento River

Lake Shasta is the primary reservoir providing flood protection on the upper Sacramento River. With a storage capacity of 4.5 million acre-feet, Lake Shasta has a capacity equal to Folsom and Oroville reservoirs combined. Lake Shasta reserves 1.3 million acre-feet of storage for flood control. This flood control capacity must be available starting October 1st in anticipation of winter storms; the reservoir is managed for flood control (reservoir levels maintained below a certain level) through March. Shasta Dam can release 79,000 cubic feet per second (cfs) safely into the Sacramento River in non-emergency flood conditions; however, normal flood releases are usually much lower.

Reclamation's operational strategy for releases from Lake Shasta is to evaluate the forecasted tributary flows below Lake Shasta and reduce Keswick Dam releases during high flows in the tributaries. This operation normally prevents the

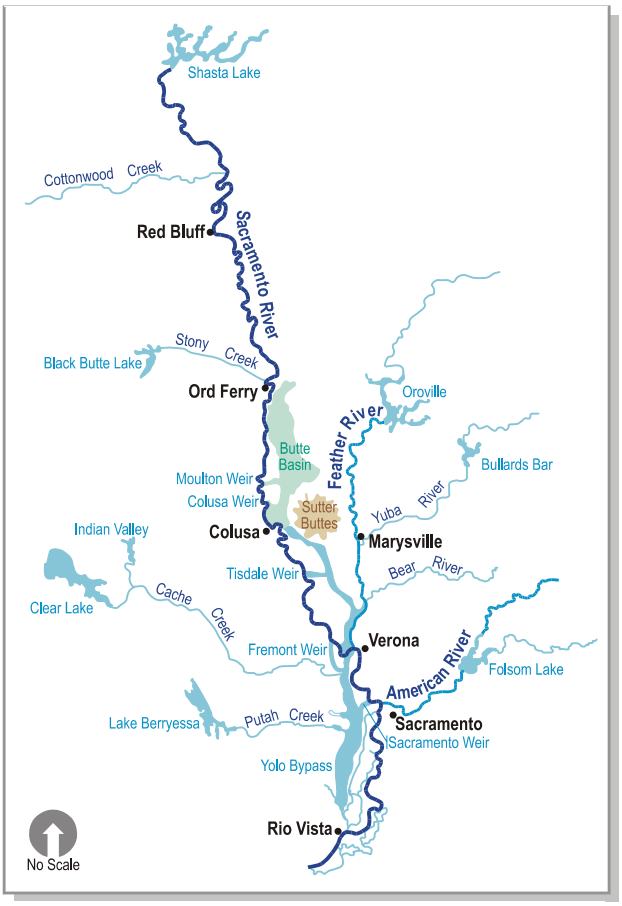

Figure 15-2
Sacramento River Flood Management System

Sacramento River flow at the Bend Bridge gage near Red Bluff from exceeding 100,000 cfs (The Resources Agency 1999).

The Sacramento River is leveed from Ord Ferry to the southern tip of Sherman Island in the Delta. Flood control on the Sacramento River is also managed by a system of weirs and bypasses constructed by the USACE (Figure 15-2). The system includes five bypasses: the Butte Basin, Sutter Bypass, Yolo Bypass, Tisdale Bypass, and Sacramento Bypass. Moulton and Colusa Weirs feed floodwaters into the Butte Basin Bypass, Tisdale Weir flows into Sutter Bypass, and Fremont Weir and Sacramento Bypass flow into the Yolo Bypass. The Yolo Bypass carries five-sixths of the volume of the Sacramento River at peak flood flows. The bypasses are large tracts of undeveloped or minimally-developed land. Development within the bypasses typically is limited to agricultural activities that require minimal infrastructure. Water released to the bypass system flows south into the Delta, in effect creating a short-term storage system for the floodwaters. Water released to the bypass system also infiltrates into the ground, recharging groundwater supplies, although this volume is small compared to the total volume of a flood. When flooding occurs, the weir and bypass system diverts water to protect the levee system and free flood storage capacity in the reservoirs. The bypasses also provide waterfowl habitat and portions of them are managed for wildlife.

The Sacramento River Flood Control Project (SRFCP), consisting of levees built by the USACE and turned over to the State for maintenance, provides flood protection for the lower reach of the Sacramento River and into the Delta. Since the authorization of the SRFCP in 1917, the effectiveness of the SRFCP has increased with the completion of multi-purpose reservoirs that provide flood control storage: Lake Shasta in 1945; Folsom Lake in 1956; Lake Oroville in 1968; and New Bullards Bar Reservoir in 1970 (State of California DWR 1998).

15.1.2.4 Feather River

Lake Oroville holds winter and spring runoff for release into the Feather River. During wet years, Lake Oroville aids in reducing downstream flooding. Up to 750,000 acre-feet of the 3.5 million acre-feet of storage capacity is maintained to capture inflows as required by the USACE. From October through March, between

2.8 and 3.2 million acre-feet of storage is the maximum allowable in order to reserve space for flood flows. From April through June, the storage limit increases, reflecting less need for flood storage space. The maximum allowed storage limit decreases again in September in preparation for the upcoming flood season. Flood control releases are made based on a release schedule and in consultation with the USACE. During times when flood control space is not required to accomplish flood control objectives, reservoir space can be used for storing water (State of California DWR 2001).

The Feather River is leveed from its confluence with the Sacramento River to Hamilton Bend near the City of Oroville on the east bank, and from the confluence to Honcut Creek on the west bank. The lower-most dam on the Feather River, Oroville Dam, regulates downstream flows, and is located at the confluence of the West Branch and the North, Middle, and South Forks of the Feather River, upstream from the Yuba and Bear tributaries.

15.1.2.5 Yuba River

New Bullards Bar Dam is operated by Yuba County Water Agency (WA). The reservoir has a maximum of 960,000 acre-feet of storage. New Bullards Bar Reservoir, on the North Fork of the Yuba River, is part of the Yuba River drainage basin. New Bullards Bar Reservoir provides flood control space between mid-September and the end of May each year. There are 170,000 acre-feet of flood control storage in New Bullards Bar Reservoir between the end of October and the end of March. The amount of flood control storage in the reservoir varies from mid September through October (depending on early season rainfall) and from the end of March through May (depending on the amount of snowfall in the watershed). This flood storage aids in keeping flows along the Yuba River within the designed capacity of its levees, 135,000 cfs.

Water released from the New Bullards Bar Reservoir joins flows from the Middle and South Forks of the Yuba River, which then passes the Englebright Dam and further downstream, the Daguerre Point Dam. The Englebright reservoir is not used for flood control or consumptive uses, but rather was built as a structure to prevent mining debris from continuing downstream. At a total capacity of 70,000 acre-feet, Englebright reservoir does not play a significant role in flood control. There are no large dams detaining flows on the Middle and South Forks of the Yuba River; New Bullards Bar Reservoir on the North Fork regulates only a third of the flow in the Yuba watershed (USACE 1999). As such, flood control has historically been a major problem downstream, at the confluence of the Yuba and Feather Rivers.

15.1.2.6 American River

Levees along the American River extend from the mouth of the River to the Mayhew Drain on the south bank. Non-Federal levees extend from this point to Sunrise Boulevard. On the north bank, Federal levees extend from the mouth to Carmichael Bluffs, constructed through the American River Flood Control Project.

There are several reservoirs along the American River; however, they are operated primarily for water supply and hydropower with the exception of Folsom Reservoir. The upstream reservoirs do not have dedicated space or physical structures for flood control, but they can be beneficial in reducing flows heading downstream towards Folsom Reservoir in some years. The three largest upstream reservoirs, French Meadows, Hell Hole, and Union Valley, can provide up to 200,000 acre-feet of usable flood storage capacity (Reclamation 2001).

Folsom Lake is the only reservoir operated for flood control on the American River. Folsom Dam and Reservoir provide flood protection for 350,000 residents and over $30 billion worth of damageable property that currently occupies the floodplain in the Sacramento metropolitan area (Reclamation 2001). Under the existing authorized operating criteria, 400,000 to 670,000 acre-feet of the total storage of 975,000 acre-feet in Folsom Reservoir is allocated to flood control during the flood control season (see fuller description in the following paragraph). The levees along the American River, constructed by the USACE in 1958, allow Folsom Reservoir to release water safely to a maximum design release of 115,000 cfs (Reclamation 2001).

The American River Watershed Investigation was created to evaluate existing flood control deficiencies after the 1986 flood along the American River. In response to the investigation's findings, a county-level joint agency was established with the long-term goal of providing urbanized sections of the Sacramento area with as much flood protection as possible. The agency, termed SAFCA, the Sacramento Area Flood Control Agency, has worked with the State of California, the USACE, and the Bureau of Reclamation to complete needed levee improvements and re-operate Folsom Dam to provide for further flood protection. In cooperation with SAFCA, Reclamation has changed to variable operating criteria, allowing as much as 670,000 acre-feet of flood control storage if 200,000 acre-feet of water supply are stored in the 3 largest upstream reservoirs.

15.1.2.7 San Joaquin River

Levees along the San Joaquin River are constructed from the Delta upstream to the mouth of the Merced River and along several San Joaquin River tributaries. In addition to levees, the San Joaquin River has a series of major flood control dams along the western slope of the southern Sierra Nevada. These include: Friant Dam on the San Joaquin River; New Exchequer Dam on the Merced River; Don Pedro Dam on the Tuolumne River; New Melones Dam on the Stanislaus River; and Camanche Reservoir on the Mokelumne River. (See Figure 15-3.)

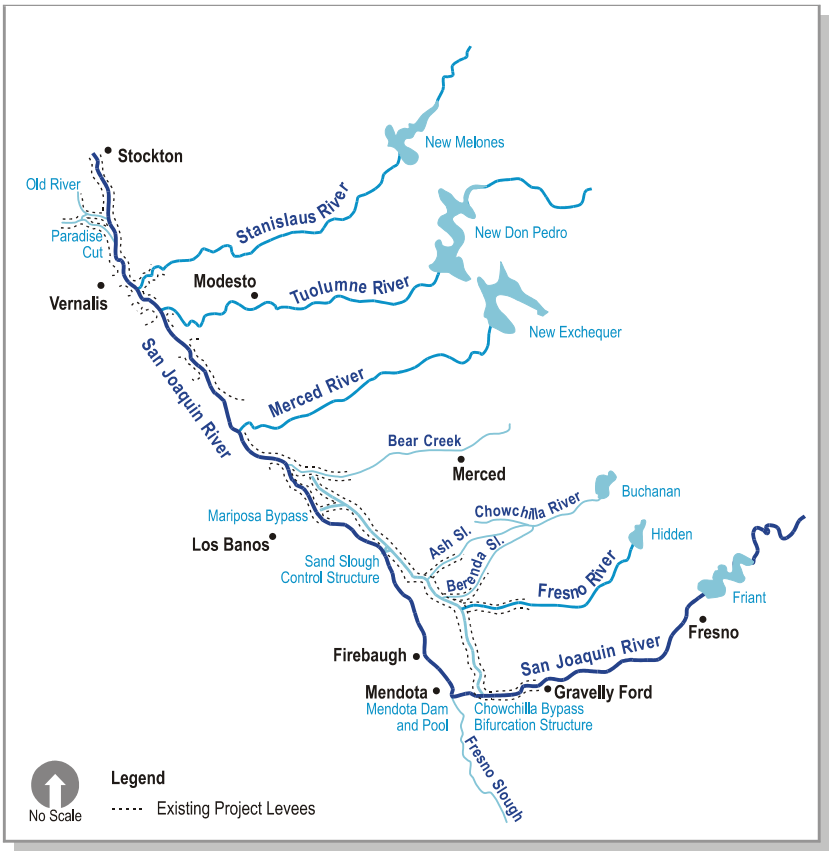

Figure 15-3
San Joaquin River Flood Management System

15.1.2.8 Merced River

The Merced River does not have a State or federal levee system, but it does contain a system of privately owned levee structures. Private landowners have maintained these levees in order to protect their agricultural lands and homes. Under USACE flood control operations rules, the New Exchequer Dam can release a maximum of 6,000 cfs from Lake McClure into the Merced River. Of a maximum capacity of just over one million acre-feet in Lake McClure, 350,000 acre-feet of storage space is reserved for flood control between mid-October and mid-March. A complete set of flood control operational guidelines as set by the USACE is contained in a document entitled, "New Exchequer Dam and Reservoir, Merced River, California – Water Control Manual"(Stillwater Sciences 2001).

15.1.3 Delta

Unlike the system of reservoirs and weirs that control the magnitude of flooding on the rivers upstream from the Delta, the flood control system in the Delta (with the exception of the Delta Cross Channel control gates) operates passively.

Since the construction of the Central Valley Project/State Water Project, and more importantly, the Yolo Bypass system, flood flows in the Delta have been more controlled. Flooding still occurs, but has been confined to the individual islands or

tracts and is due mostly to levee instability or overtopping. The major factors influencing Delta water levels include high flows, high tide, and wind. The highest water stages occur December - February when these factors are compounded.

15.1.4 Export Service Area

Complex systems, including reservoirs, levees, bypasses, and weirs provide flood protection to the lowlands in the Export Service Area. The Export Service Area includes Anderson Reservoir in Santa Clara Valley Water District, parts of the San Joaquin Valley including the Tulare Lake Basin, the California Aqueduct, the East and West Branches that convey water to Lake Perris, Diamond Valley Lake, and Castaic Lake, and the Colorado River Aqueduct that supplies water to Lake Mathews.

Anderson Reservoir is on Coyote Creek downstream from Coyote Reservoir in the Mt. Hamilton foothills. Water draining from the Mt. Diablo Range supplies Anderson Reservoir. Santa Clara Valley Water District operates the reservoir for 1) impounding local surface runoff, 2) providing incidental flood control benefits, 3) providing controlled releases of reservoir water to the Almaden Valley Pipeline via the Cross Valley Pipeline and for groundwater recharge, and 4) providing source water to water treatment plants under emergency conditions. Storage space is also maintained in Anderson Reservoir for excess flows from Coyote Reservoir via Coyote Creek. Maximum storage in Anderson Reservoir typically occurs in April; the District targets a reduction in storage to minimum levels to provide space for local runoff by December 1st. (Santa Clara Valley Water District 2002).

Operating rules at all Santa Clara Valley Water District reservoirs include limited provisions to release water to reduce flood probability. In 1997, the District adopted operating strategies for some reservoirs to reduce flood probability while minimizing any impacts on water supply. These strategies recognize that if the reservoir storage approaches full early enough in the rainfall season, some water can be released to create increased flood storage without significantly reducing the probability of filling the reservoir by the end of the season. The flood control rule curves identify reservoir storage for a given date from November 15th through April. If the actual storage on that date is above the curve, releases may be made to provide for potential flood peak attenuation. Releases to reach the rule curve are coordinated with the National Weather Service Quantitative Precipitation Forecasts to predict flowrates in the uncontrolled watershed downstream of the reservoirs. Releases are discontinued temporarily when predicted flowrates exceed a safe level. (Maher 2003).

The Tulare Lake Basin does not have an outlet to the ocean. Consequently, effective flood management is a key element in protecting downstream residences and resources. There are four major rivers in this basin, the Kings, Kaweah, Tule, and Kern Rivers. These rivers flow from the Sierra Nevada Mountains into the lowlands of the Tulare Lake Basin. An extensive system of levees and diversions in the lowlands provide protection from irrigation flows, minor flood flows, and surrounding uncontrolled local runoff. However, the operations of flood control reservoirs and

diversion structures upstream, along all four rivers, must be carefully coordinated to provide an adequate level of flood protection to the Tulare Lake lowlands.

Along the Kings River, a system of weirs are designed to divert flood flows through the Kings River North, James Bypass, Fresno Slough, and Mendota Pool system north into the San Joaquin River system. The Kern River Intertie may also be used to divert flood flows from the Kern River into the California Aqueduct.

The California Aqueduct is the main conveyance facility for the State Water Project, (SWP), conveying water from the Banks Pumping Plant to San Luis Reservoir and to SWP water contractors in the South Bay, San Joaquin Valley, and Southern California. This aqueduct divides into two branches, the East and West Branches in the Antelope Valley. (See Figure 15-4.) Water in the East Branch can be transported to Silverwood Lake and then conveyed into Lake Perris or directly to Diamond Valley Lake. The West Branch conveys water into Pyramid Lake in Los Angeles County, continues to Elderberry Forebay, ending at Castaic Lake.

There are no formal flood control allocations for Castaic Lake, Lake Perris, or Diamond Valley Lake. However, during a wet year, or if large storms are anticipated, up to 30,000 acre-feet can be reserved in Castaic Lake as flood control storage (Leahigh 2003). Local runoff from Elizabeth, Elderberry, Necktie, Fish, and Castaic Creeks enter Castaic Lake. Elizabeth Creek provides the largest inflow into Castaic Lake; all five creeks combined supply approximately 100 cfs inflow into Castaic Lake (Young 2003). Flood flows from the Tulare Lake Basin are released into the California Aqueduct and can be captured downstream by Castaic Lake. DWR is responsible for flood control operations.

A substantial amount of runoff does not enter Lake Perris or Diamond Valley Lake. These reservoirs do not provide substantive flood control benefit for the region or locally.

Lake Mathews, a terminal reservoir for the Colorado River Aqueduct, is owned by Metropolitan WD. There are no formal flood control operations on Lake Mathews.

15.2 Environmental Consequences/Environmental Impacts

15.2.1 Assessment Methods

Assessment methods are separated into two sections in this discussion: flood management operations and levee systems. The flood management operations analysis focuses on the flood control system's ability to handle flood flows under the program alternatives from a storage perspective. The analysis of the levee system focuses on the system's ability to handle the flood flows from a geotechnical perspective.

Flood control storage, reservoir operations, and channel capacity (information collected through literature review and personal communication as noted) are presented and compared to movement of water under EWA actions. Modeling results (see Appendix H) provide data regarding reservoir elevations and river flows for areas affected by EWA actions.

15.2.2 Significance Criteria

An effect on flood management operations is considered significant if the program would:

- Conflict with the flood control operation of a reservoir because of the presence of additional EWA water; or
- Increase river flows above channel capacity.

An effect on the levee system is considered potentially significant if the program would:

- Decrease levee stability through increased flood stages, excessive seepage and scour, or increased deposition.

15.2.3 Environmental Consequences/Environmental Impacts of the No Action/No Project Alternative

Under the No Action/No Project Alternative, water transfers as part of the EWA would not occur. Reservoir operations, including carryover storage, flood storage capacity, and timing of releases would remain consistent with existing conditions. River channel capacities with regard to flood control would remain constant and would continue to be managed according to existing guidelines. The No Action/No Project Alternative reflects that of the existing conditions/affected environment description and is termed Baseline Condition in the following sections.

15.2.4 Environmental Consequences/Environmental Impacts of the Flexible Purchase Alternative

The Flexible Purchase Alternative allows transfers up to 600,000 acre-feet and does not specify transfer limits in the Upstream from the Delta Region or the Export Service Area. Transfers in the Upstream from the Delta Region would range from 50,000 to 600,000 acre-feet, limited by hydrologic year and conveyance capacity through the Delta. Although all potential transfers would not occur in one year, this section discusses all transfers (a transfer amount that would result in greater than 600,000 acre-feet) to provide an effects analysis of a maximum transfer scenario. Similarly, the evaluation includes an analysis of up to 540,000 acre-feet in the Export Service Area to cover the maximum transfer scenario for that region.

15.2.4.1 Upstream from the Delta Region

15.2.4.1.1 Sacramento River

EWA acquisition of Sacramento River contractor water via groundwater substitution and crop idling would increase Sacramento River flows in April through September. The Sacramento River would increase in flow downstream from the point of diversion as water released from Lake Shasta was not diverted. Flow is also increased below Keswick Dam because the release pattern is shifted from August and September to July to take advantage of Delta export capacity in July. The increase in flows would not occur during the flood season. River flows would be maintained well below the river channel carrying capacity during transfers. Table 15-1 shows the releases from Keswick Dam under the existing conditions and with the EWA.[1] The channel capacity below Keswick Dam is 79,000 cfs, much higher than the expected release with the EWA. Because the average Baseline Condition flows are substantially below the channel capacity, the additional flows with the EWA are only slightly greater than the Baseline Condition, and the increase in flows occurs during the irrigation season rather than the flood season, the EWA would not affect flood control.

The EWA would not affect levees because it would not substantially increase flows. Therefore, no program-related effects to levee stability, such as erosion or seepage, would occur beyond the Baseline Condition. There would be no effect on flood control from increased river flows.

The Feather, Yuba, and American Rivers contribute flows to the Sacramento River. EWA actions would not cause substantial increases in flow on these rivers compared to the Baseline Condition; therefore, EWA actions would not affect flood control on the lower Sacramento River. (See Sections 15.2.4.1.2 – 15.2.4.1.4.)

Table 15-1
Long-term Average Release from Keswick Dam

Month	Monthly Mean Flow (cfs)		Difference (cfs)
	Baseline	With EWA	
Oct	5,842	5,842	0
Nov	4,854	4,854	0
Dec	6,672	6,672	0
Jan	7,951	7,951	0
Feb	10,056	10,056	0
Mar	8,249	8,249	0
Apr	7,706	7,706	0
May	8,381	8,381	0
Jun	10,529	10,529	0
Jul	13,284	13,524	240
Aug	10,556	10,423	-133
Sep	7,278	7,167	-111

[1] Effects on flood control are analyzed based on the releases from Keswick Dam rather than Sacramento River flows at a point downstream from Keswick Dam. If EWA actions met release thresholds below Keswick Dam, EWA actions would also meet channel capacity thresholds further downstream.

15.2.4.1.2 Feather River

EWA acquisition of Oroville-Wyandotte Irrigation District (ID) stored reservoir water would cause the surface water elevation in Lake Oroville to be higher compared to the Baseline Condition from the November preceding likely fish actions until the following September. The EWA agencies would acquire stored reservoir water from Sly Creek Reservoir and Little Grass Valley Reservoir in November and December before fish actions are likely. Water released from the reservoirs would be stored in Lake Oroville until transfer the following summer. Because of the stored water, Lake Oroville's surface water elevation would be higher from November until the transfer the following summer compared to the Baseline Condition. The additional water held in Lake Oroville would be stored in the portion of the reservoir dedicated to water supply (the conservation pool). The amount of space between the top of conservation pool and the capacity of the reservoir (the space dedicated to flood control) would not change with the EWA. As long as the water levels in Lake Oroville were maintained below the dedicated flood control space, the addition of EWA water to Lake Oroville would not conflict with reservoir operations.

Under certain hydrologic conditions, high inflows to Lake Oroville could cause water levels to encroach on flood control space. The water control manual for Lake Oroville specifies release requirements necessary to reduce the lake elevation. The presence of the EWA water in the reservoir could cause required flood control releases to occur sooner than under the Baseline Condition. The addition of EWA water to Lake Oroville would not cause the operational guidelines of the lake regarding releases to be changed. Thus, the effects on flood control due to the acquisition of stored reservoir water from Oroville-Wyandotte ID would be less than significant.

EWA acquisition of Feather River contractor water via groundwater substitution and crop idling would create a higher water surface elevation in Lake Oroville from April through June compared to the Baseline Condition. Lake Oroville would not hold any EWA water during the flood season because of groundwater substitution or crop idling. There would be no effect on flood control from water held in Lake Oroville during April through September.

EWA acquisition of Feather River contractor water via groundwater substitution and crop idling would increase Feather River flows downstream from Lake Oroville in July and August. The Feather River would increase in flow downstream from the point of diversion as water held in Lake Oroville was released. Flow is also increased because the release pattern is shifted from August and September to July to take advantage of Delta export capacity in July. The increase in flows would not occur during the flood season. River flows would be maintained well below the river channel carrying capacity during transfers. Table 15-2 shows the releases from Lake Oroville under the existing conditions and with the EWA.[2] The channel capacity below Lake Oroville is

[2] Effects on flood control are analyzed based on the releases from Lake Oroville rather than Feather River flows at a point downstream from Lake Oroville. If EWA actions met release thresholds below Lake Oroville, EWA actions would also meet channel capacity thresholds further downstream.

210,000 cfs, much higher than the expected flows with the EWA. Because the average Baseline Condition flows are substantially below the channel capacity, the additional flows with the EWA are only slightly greater than the Baseline Condition, and the increase in flows occurs during the irrigation season rather than the flood season, there would not be an effect on flood control.

Table 15-2
Long-term Average Flow Below Thermalito Afterbay

Month	Monthly Mean Flow (cfs)		Difference (cfs)
	Baseline	With EWA	
Oct	2,441	2,441	0
Nov	2,301	2,301	0
Dec	3,984	3,984	0
Jan	5,005	5,005	0
Feb	5,930	5,930	0
Mar	6,144	6,144	0
Apr	3,416	3,416	0
May	3,826	3,604	-222
Jun	5,084	4,788	-296
Jul	5,896	6,497	601
Aug	4,434	4,515	81
Sep	1,600	1,421	-179

The EWA would not affect levees because it would not substantially increase flows. Therefore, no program-related effects to levee stability, such as erosion or seepage, would occur beyond the Baseline Condition. The EWA would have no effect on flood control from increased river flows.

EWA acquisition of Oroville-Wyandotte Irrigation District (ID) stored reservoir water would decrease the surface water elevation in Sly Creek and Little Grass Valley Reservoirs compared to the Baseline Condition from November until refill. Lower water surface elevation in Sly Creek and Little Grass Valley Reservoirs would incidentally provide space for flood control. A decrease in reservoir elevation in would increase the amount of inflow that could be captured during a flood event. This would be a potentially beneficial effect.

15.2.4.1.3 Yuba River

EWA acquisition of Yuba County WA water via groundwater substitution would create a higher water surface elevation in New Bullards Bar Reservoir from April through September compared to the Baseline Condition. The surface water elevation would be higher with the EWA compared to the Baseline Condition, from April through September. New Bullards Bar Reservoir would not hold any EWA water during the flood season. There would be no effect on flood control from water held in New Bullards Bar Reservoir during April through September because of groundwater substitution.

EWA acquisition of Yuba County WA stored reservoir water would decrease surface water elevations from July to refill at New Bullards Bar Reservoir. Entering the flood season, the surface elevation at New Bullards Bar Reservoir would be lower than the Baseline Condition. A reduction of water in New Bullards Bar Reservoir could lessen the number of flood releases and/or the amount of water needed to be released. As noted previously, the lack of major flood control dams on the Middle and South Forks of the Yuba River historically resulted in flood control problems at the confluence of the Yuba and Feather Rivers. The additional space made available in New Bullards Bar Reservoir because of the release of stored reservoir water would incidentally provide space for flood control. This would be a potentially beneficial effect.

EWA acquisition of Yuba County WA water via groundwater substitution and stored reservoir water would increase Yuba River flows in July through September. The Yuba River would increase in flow downstream from the point of diversion as water held in New Bullards Bar Reservoir was released. Flows would not increase during the flood season. River flows would be maintained well below the river channel carrying capacity during transfers. Flows below New Bullards Bar Reservoir would increase approximately 1,000 cfs. This increase, in addition to the average releases of 1,800, 2,000, and 1,200 cfs in July, August, and September respectively, would be well below the channel capacity of 120,000 cfs (USGS 2003). Because the average Baseline Condition flows are substantially below the channel capacity, the additional flows with the EWA are only slightly greater than the Baseline Condition, and the increase in flows occurs during the irrigation season rather than the flood season, the EWA would not affect flood control.

The EWA would not affect levees because it would not substantially increase flows. Therefore, no program-related effects to levee stability, such as erosion or seepage, would occur beyond the Baseline Condition. There would be no effect on flood control from increased river flows.

15.2.4.1.4 American River

EWA acquisition of Placer County WA water via stored groundwater purchase and stored reservoir water would create a higher water surface elevation in Folsom Lake from April through September compared to the Baseline Condition. Folsom Lake Reservoir would not hold any EWA water during the flood season. There would be no effect on flood control from water held in Folsom Lake during April through September because of stored groundwater purchase and stored reservoir water.

EWA acquisition of stored groundwater from Sacramento Groundwater Authority members and stored reservoir water would increase American River flows in July through September. The American River would increase in flow downstream from Folsom Lake as water was released. The increase in flows would occur between July and December. However, river flows would be maintained well below the river channel carrying capacity during transfers, as regulated by USACE flood control operations. Table 15-3 shows potential releases from Nimbus Dam under the Baseline Condition and with

the EWA.[3] The channel capacity below Folsom Lake is 115,000 cfs, much higher than the expected release with the EWA. The average Baseline Condition flows are substantially below the channel capacity and the additional flows with the EWA are only slightly greater than the Baseline Condition; there would be a less than significant effect on flood control.

Table 15-3
Long-term Average Release from Nimbus Dam

Month	Monthly Mean Flow (cfs)		Difference (cfs)
	Baseline	With EWA	
Jan	4,124	4,124	0
Feb	4,989	4,989	0
Mar	3,941	3,941	0
Apr	3,616	3,616	0
May	3,793	3,793	0
Jun	4,166	4,166	0
Jul	4,100	4,316	216
Aug	2,482	2,574	92
Sep	2,876	2,894	18

The EWA would not affect levees because it would not substantially increase flows. Therefore, no program-related effects to levee stability, such as erosion or seepage, would occur beyond the Baseline Condition. Therefore, the effects would be less than significant.

EWA acquisition of Placer County WA stored reservoir water would decrease surface water elevations July to refill at Hell Hole and/or French Meadows reservoirs. The surface water elevation at Hell Hole and/or French Meadows Reservoir would be lower than the Baseline Condition from September until refill. Although not operated for flood control, the additional storage space would potentially attenuate flows entering Folsom Lake. This effect would be potentially beneficial.

15.2.4.1.5 Merced River

EWA acquisition of Merced ID water via groundwater substitution would increase surface water elevation in Lake McClure from April through November. Water held in Lake McClure would not be released until October and November. The additional water held in Lake McClure would be stored in the portion of the reservoir dedicated to water supply (the conservation pool). The amount of space between the top of conservation pool and the capacity of the reservoir (the space dedicated to flood control) would not change with the EWA. As long as the water levels in Lake McClure were maintained below the dedicated flood control space, the addition of EWA water to Lake McClure would not conflict with reservoir operations. As long as the water levels in Lake McClure were maintained below the dedicated flood control

[3] Effects on flood control are analyzed based on the releases from Nimbus Dam rather than American River flows at a point downstream from Nimbus Dam. If EWA actions met release thresholds below Nimbus Dam, EWA actions would also meet channel capacity thresholds further downstream.

space, the addition of EWA water to Lake McClure would not conflict with reservoir operations.

Under certain hydrologic conditions, high inflows to Lake McClure could cause water levels to encroach on flood control space. The water control manual for Lake McClure specifies release requirements necessary to reduce the lake elevation. The presence of the EWA water in the reservoir could cause required flood control releases to occur sooner than under the Baseline Condition. The addition of EWA water to Lake McClure would not cause the operational guidelines of the lake regarding releases to be changed. Thus, the effects on flood control due to the acquisition of water via groundwater substitution from Merced ID would be less than significant.

EWA acquisition of Merced ID water via groundwater substitution would increase Merced River flows downstream from the point of diversion in October and November. The Merced River would increase in flow downstream from Lake McClure as water was released. The increase in flows would occur during the start of the flood season. However, river flows would be maintained well below the river channel carrying capacity during transfers, as regulated by USACE flood control operations. Table 15-4 shows the releases from Lake McClure under the Baseline Condition and with the EWA. The New Exchequer Dam can release a maximum of 6,000 cfs from Lake McClure into the Merced River. The flows with the EWA would be much lower than the maximum.

Table 15-4
Long-term Average Flow Below Crocker-Huffman Dam

Month	Monthly Mean Flow (cfs)		Difference (cfs)
	Baseline	With EWA	
Oct	812	1,015	203
Nov	231	441	210
Dec	353	353	0
Jan	493	493	0
Feb	784	784	0
Mar	500	500	0
Apr	501	501	0
May	894	894	0
Jun	881	881	0
Jul	329	329	0
Aug	159	159	0
Sep	178	178	0

The EWA would not affect levees because it would not substantially increase flows. Therefore, no program-related effects to levee stability, such as erosion or seepage, would occur beyond the Baseline Condition. Therefore, the effects would be less than significant.

15.2.4.2 Delta Region

EWA acquisition of water in the Upstream from the Delta Region would increase inflows to the Delta. Flows in the Sacramento and San Joaquin Rivers would increase compared to the Baseline Condition, resulting in increased inflow to the Delta. Flow increases would occur at times of available pump capacity, predominantly July through September, with some increases earlier and later with crop idling, groundwater substitution, and Merced ID transfers. (See Tables 15-5 and 15-6.) The Sacramento River would contribute a greater percentage increase to flow compared to the San Joaquin River; 16 percent increase for the Sacramento River during July through September compared to 10 percent increase in October or November for the San Joaquin River. The flow increases on the Sacramento River would not take place during the flood control season. During July through September, overall Delta inflow is less, relative to Delta inflow during December through March. The Delta inflow on the San Joaquin River is also less, relative to the Delta inflow during January through June. Because the Delta annually receives higher inflows than would occur with the EWA, and the increases in inflow would not occur during the Delta's highest water stages, December through February, the effect on the Delta would be less than significant.

Table 15-5
Long-term Average Delta Inflow from the Sacramento River

15.2.4.3 Export Service Area

EWA management of Santa Clara Valley WD water via predelivery could increase the surface water elevation in Anderson Reservoir in the months prior to the high point[4] in San Luis Reservoir. With the EWA, water would be transferred from San Luis Reservoir to Anderson Reservoir or groundwater storage facilities prior to the high point in San Luis Reservoir. Although the amount of water within Anderson Reservoir would increase compared to the Baseline Condition, flood storage capacity would be maintained to accept inflows from Coyote Creek based on the rule curve explained in Section 15.1.4. The presence of the EWA water in the reservoir could cause required flood control releases to occur sooner than under the Baseline Condition. In the event of a required flood release, the flood storage capacity in Anderson Reservoir would be equivalent to the capacity under the Baseline Condition; therefore, the effect on flood control would be less than significant.

Metropolitan WD management of EWA water provided as predelivery could increase the surface water elevation in Diamond Valley Lake, Lake Mathews, and other Metropolitan WD storage facilities. If Metropolitan WD were to accept predelivery water and use it to repay its flexible storage debt in Castaic Lake or Lake Perris, predelivery could affect the surface water elevations in those lakes as well. With the EWA, water could be transferred to Metropolitan WD at any of its turnouts and then to storage in Diamond Valley Lake, Lake Mathews, or other Metropolitan WD storage facilities, or used to repay flexible storage in Castaic Lake or Lake Perris. Although the amount of water within these facilities would increase compared to the Baseline Condition, flood storage capacity in

[4] High point is the value at which storage has peaked annually. In San Luis Reservoir, high point occurs approximately in mid-April.

Castaic Lake would be equivalent to the capacity under the Baseline Condition; therefore, the effect on flood control would be less than significant.

EWA management of Metropolitan WD water via source shifting could decrease surface water elevations in Castaic Lake, Lake Perris, Diamond Valley Lake, Lake Mathews, and Anderson Reservoir beginning in April and ending in December. Metropolitan WD could draw on their flexible storage in Castaic Lake or Lake Perris, draft storage in Diamond Valley Lake or Lake Mathews, or draw on other local sources in the April-September period. Santa Clara Valley WD would draw on Anderson Reservoir for local needs from April through September. Reservoir levels would be lower relative to the Baseline Condition from April until the source shift water was returned by the end of December. Lower water levels in Castaic Lake in October, November, and December could provide additional storage space for inflow from the California Aqueduct or local streams. If water were not repaid until the following year, continued lower water levels would provide space until refill. The effect on flood control would be potentially beneficial.

15.2.4.4 Multi-year Transfers

The analysis thus far has been based on a 1-year water transfer; however, the EWA agencies and willing sellers may agree to multi-year transfers. No effects as discussed would accumulate from one year to another. Therefore, the effects presented in Sections 15.2.4.1 through 15.2.4.3 would be the same whether agencies sold water for one or multiple years.

15.2.5 Environmental Consequences/Environmental Impacts of the Fixed Purchase Alternative

The Fixed Purchase Alternative specifies purchases of 35,000 acre-feet in the Upstream from the Delta Region, and 150,000 acre-feet in the Export Service Area. While the amounts in each region are fixed, the acquisition types and sources could vary. To allow the EWA Project Agencies maximum flexibility when negotiating purchases with willing sellers, this section analyzes the effects of each potential transfer. These transfers are the same actions as those described for the Flexible Purchase Alternative, but the amounts are limited by the total acquisition amount in each region (35,000 acre-feet in the Upstream from the Delta Region and 150,000 acre-feet in the Export Service Area).

15.2.5.1 Upstream from the Delta Region

As stated in the Modeling Technical Appendix (Attachment 1), the Fixed Purchase Alternative is not modeled because 35,000 acre-feet is too small an amount to model through the Delta. Any differences in the modeling output from the Baseline Condition would not represent meaningful differences. Therefore, the effects analysis for the Fixed Purchase Alternative is discussed qualitatively.

15.2.5.1.1 Sacramento River

EWA acquisition of Sacramento River contractor water via groundwater substitution and crop idling would increase Sacramento River flows in April through September. The Sacramento River would increase in flow downstream from the point of diversion as water released from Lake Shasta was not diverted. Flow is also increased below Keswick Dam because the release pattern is shifted from August and September to July to take advantage of Delta export capacity in July. The increase in flows would not occur during the flood season. River flows would be maintained well below the river channel carrying capacity during transfers. Levees would not be affected because flows would not be substantially increased. Therefore, no program-related effects to levee stability, such as erosion or seepage, would occur beyond the Baseline Condition. There would be no effect on flood control from increased river flows.

15.2.5.1.2 Feather River

EWA acquisition of Oroville-Wyandotte Irrigation District (ID) stored reservoir water would cause the surface water elevation in Lake Oroville to be higher compared to the Baseline Condition from the November preceding likely fish actions until the following September. The EWA agencies would acquire stored reservoir water from Sly Creek Reservoir and Little Grass Valley Reservoir in November and December before fish actions are likely. Water released from the reservoirs would be stored in Lake Oroville until transfer the following summer. Because of the stored water, Lake Oroville's surface water elevation would be higher from November until the transfer the following summer compared to the Baseline Condition. The additional water held in Lake Oroville would be stored in the portion of the reservoir dedicated to water supply (the conservation pool). The amount of space between the top of conservation pool and the capacity of the reservoir (the space dedicated to flood control) would not change with the EWA. As long as the water levels in Lake Oroville were maintained below the dedicated flood control space, the addition of EWA water to Lake Oroville would not conflict with reservoir operations.

Under certain hydrologic conditions, high inflows to Lake Oroville could cause water levels to encroach on flood control space. The water control manual for Lake Oroville specifies release requirements necessary to reduce the lake elevation. The addition of EWA water to Lake Oroville would not cause the operations of the lake regarding releases to be changed. The presence of the EWA water in the reservoir could cause required flood control releases to occur sooner than under the Baseline Condition. Thus, the effects on flood control due to the acquisition of stored reservoir water from Oroville-Wyandotte ID would be less than significant.

EWA acquisition of Feather River contractor water via groundwater substitution and crop idling would create a higher water surface elevation in Lake Oroville from April through June compared to the Baseline Condition. Lake Oroville would not hold any EWA water during the flood season because of groundwater substitution or crop idling. There would be no effect on flood control from water held in Lake Oroville during April through September.

EWA acquisition of Feather River contractor water via groundwater substitution and crop idling would increase Feather River flows downstream from Lake Oroville in July and August. The Feather River would increase in flow downstream from the point of diversion as water held in Lake Oroville was released. Flow is also increased because the release pattern is shifted from August and September to July to take advantage of Delta export capacity in July. The increase in flows would not occur during the flood season. River flows would be maintained well below the river channel carrying capacity during transfers. The channel capacity below Lake Oroville is 210,000 cfs, much higher than the expected release with the EWA. Levees would not be affected because flows would not be substantially increased. Therefore, no program-related effects to levee stability, such as erosion or seepage, would occur beyond the Baseline Condition. There would be no effect on flood control from increased river flows.

EWA acquisition of Oroville-Wyandotte Irrigation District (ID) stored reservoir water would decrease the surface water elevation in Sly Creek and Little Grass Valley Reservoirs compared to the Baseline Condition from November until refill. Lower water surface elevation in Sly Creek and Little Grass Valley Reservoirs would incidentally provide space for flood control. A decrease in reservoir elevation in would increase the amount of inflow that could be captured during a flood event. This would be a potentially beneficial effect.

15.2.5.1.3 Yuba River

EWA acquisition of Yuba County WA water via groundwater substitution would create a higher water surface elevation in New Bullards Bar Reservoir from April through September compared to the Baseline Condition. The surface water elevation would be higher with the EWA compared to the Baseline Condition from April through September. New Bullards Bar Reservoir would not hold any EWA water during the flood season. There would be no effect on flood control from water held in New Bullards Bar Reservoir during April through September because of groundwater substitution.

EWA acquisition of Yuba County WA stored reservoir water would decrease surface water elevations from July to refill at New Bullards Bar Reservoir. Entering the flood season, the surface elevation at New Bullards Bar Reservoir would be lower than the Baseline Condition. A reduction of water in New Bullards Bar Reservoir could lessen the number of flood releases and/or the amount of water needed to be released. As noted previously, the lack of major flood control dams on the Middle and South Forks of the Yuba River historically resulted in flood control problems at the confluence of the Yuba and Feather Rivers. The additional space made available in New Bullards Bar Reservoir because of the release of stored reservoir water would incidentally provide space for flood control. This would be a potentially beneficial effect.

EWA acquisition of Yuba County WA water via groundwater substitution and stored reservoir water would increase Yuba River flows in July through September. The Yuba River would increase in flow downstream from the point of diversion as water held in New Bullards Bar Reservoir was released. The increase in flows would not occur during the flood season. River flows would be maintained well below the river channel carrying capacity during transfers. Levees would not be affected because flows

would not be substantially increased. Therefore, no program-related effects to levee stability, such as erosion or seepage, would occur beyond the Baseline Condition. There would be no effect on flood control from increased river flows.

15.2.5.1.4 American River

EWA acquisition of Placer County WA water via stored groundwater purchase and stored reservoir water would create a higher water surface elevation in Folsom Lake from April through September compared to the Baseline Condition. Folsom Lake Reservoir would not hold any EWA water during the flood season. There would be no effect on flood control from water held in Folsom Lake during April through September because of stored groundwater purchase and stored reservoir water.

EWA acquisition of stored groundwater from Sacramento Groundwater Authority members and stored reservoir water would increase American River flows in July through December. The American River would increase in flow downstream from Folsom Lake as water was released. The increase in flows would occur between July and December. However, river flows would be maintained well below the river channel carrying capacity during transfers, as regulated by USACE flood control operations. The channel capacity below Folsom Lake is 115,000 cfs, much higher than the expected release with the EWA. Levees would not be affected because flows would not be substantially increased. Therefore, no program-related effects to levee stability, such as erosion or seepage, would occur beyond the Baseline Condition. Therefore, the effects would be less than significant.

EWA acquisition of Placer County WA stored reservoir water would decrease surface water elevations July to refill at Hell Hole and/or French Meadows reservoirs. The surface water elevation at Hell Hole and/or French Meadows Reservoir would be lower than the Baseline Condition from July until refill. Although not operated for flood control, the additional storage space would potentially attenuate flows entering Folsom Lake. This effect would be potentially beneficial.

15.2.5.1.5 Merced River

EWA acquisition of Merced ID water via groundwater substitution would increase surface water elevation in Lake McClure from April through November. Water held in Lake McClure would not be released until October and November. The additional water held in Lake McClure would be stored in the portion of the reservoir dedicated to water supply (the conservation pool). The amount of space between the top of conservation pool and the capacity of the reservoir (the space dedicated to flood control) would not change with the EWA. As long as the water levels in Lake McClure were maintained below the dedicated flood control space, the addition of EWA water to Lake McClure would not conflict with reservoir operations.

Under certain hydrologic conditions, high inflows to Lake McClure could cause water levels to encroach on flood control space. The water control manual for Lake McClure specifies release requirements necessary to reduce the lake elevation. The addition of EWA water to Lake McClure would not cause the operations of the lake regarding releases to be changed. The presence of the EWA water in the reservoir could cause

required flood control releases to occur sooner than under the Baseline Condition Thus, the effects on flood control due to the acquisition of water via groundwater substitution from Merced ID would be less than significant.

EWA acquisition of Merced ID water via groundwater substitution would increase Merced River flows downstream from the point of diversion in October and November. The Merced River would increase in flow downstream from Lake McClure as water was released. The increase in flows would occur during the start of the flood season. However, river flows would be maintained well below the river channel carrying capacity during transfers, as regulated by USACE flood control operations. Under USACE flood control operations rules, the New Exchequer Dam can release a maximum of 6,000 cfs from Lake McClure into the Merced River. The flows with the EWA would be much lower than the maximum. Levees would not be affected because flow levels are below channel capacity. Therefore, no program-related effects to levee stability, such as erosion or seepage, would occur beyond the Baseline Condition. Therefore, the effects would be less than significant.

15.2.5.2 Delta Region

EWA acquisition of water in the Upstream from the Delta Region would increase inflows to the Delta. The greatest amount of water that could be conveyed through the Delta under the Fixed Purchase Alternative is 35,000 acre-feet. The increase in Delta inflow would take place predominantly in July through November, depending on transfer sources. As stated in the Modeling Technical Appendix (Attachment 1), the Fixed Purchase Alternative is not modeled because 35,000 acre-feet is too small an amount to model through the Delta. Any differences in the modeling output from the Baseline Condition would not represent meaningful differences. The Delta inflow with the EWA would be lower than Delta inflow during much of the year, and the increased inflow would not be during the Delta's highest water stages, December through February. The effect on the Delta would be less than significant.

15.2.5.3 Export Service Area

The effects of source shifting and predelivery under the Fixed Purchase Alternative are equivalent to the effects as described under the Flexible Purchase Alternative because the transfer amounts are the same under both Alternatives. Therefore, as stated in Section 15.2.4.3, the effect of source shifting on flood control would be potentially beneficial; the effect of predelivery on flood control would be less than significant.

15.2.5.4 Multi-year Transfers

The analysis thus far has been based on a 1-year water transfer; however, the EWA agencies and willing sellers may agree to multi-year transfers. No effects as discussed would accumulate from one year to another. Therefore, the effects presented in Sections 15.2.5.1 through 15.2.5.3 would be the same whether agencies sold water for one or multiple years.

15.2.6 Comparative Analysis of Alternatives

This section has thus far analyzed the effects of many potential transfers, looking at the "worst-case scenario" that would occur if all acquisitions happened in the same year. This approach ensures that all effects of transfers are included, and provides the EWA Project Agencies the flexibility to choose transfers that may be preferable in a given year. The EWA, however, would not actually purchase all of this water in the same year. This section provides information about how EWA would more likely operate in different year types.

The following discussion compares the actions taken under the Flexible and Fixed Purchase Alternatives during wet and dry years. A further comparison of the alternatives is listed in Table 15-7.

Table 15-7
Comparison of the Effects of the Flexible and Fixed Purchase Alternatives on Flood Control

Decreases are release to point of diversion. Below point of diversion there are no decreases.
Increases are below point of diversion. Increases are less above point of diversion.

Region	*Asset Acquisition or Management*	*Result*	*Impacts*	*Flexible Purchase Alternative Change from Baseline Condition*	*Fixed Purchase Alternative Change from Baseline Condition*	*Significance of Flexible Purchase Alternative*	*Significance of Fixed Purchase Alternative*
Sacramento River	Groundwater substitution/ Crop Idling	Water released from Lake Shasta in April through September is not diverted.	Increase in Sacramento River flow April through September.	Releases from Keswick Dam increase by a maximum of 240 cfs.	Releases from Keswick Dam increase.	No effect	No effect
Feather River	Stored reservoir water	Water is released from Sly Creek and Little Grass Valley Reservoirs.	Sly Creek and Little Grass Valley Reservoir levels decrease from December until refill.	A decrease in elevation in Sly Creek and Little Grass Valley Reservoirs would increase the amount of inflow that could be captured during a flood event	A decrease in elevation in Sly Creek and Little Grass Valley Reservoirs would increase the amount of inflow that could be captured during a flood event	Potential Beneficial Effect	Potential Beneficial Effect
			Stored reservoir water released from Little Grass Valley and Sly Creek Reservoirs is stored in Lake Oroville.	Lake Oroville's surface water elevation would increase compared to the Baseline Condition while holding the stored reservoir water	Lake Oroville's surface water elevation would increase compared to the Baseline Condition while holding the stored reservoir water	LTS	LTS
	Groundwater substitution/ Crop idling	Water is released from Lake Oroville	Increase in Feather River flow July through September.	Releases from Lake Oroville increase by a maximum of 600 cfs.	Releases from Lake Oroville increase.	No effect	No effect

Increases are below point of diversion. Increases are less above point of diversion.

Region	*Asset Acquisition or Management*	*Result*	*Impacts*	*Flexible Purchase Alternative Change from Baseline Condition*	*Fixed Purchase Alternative Change from Baseline Condition*	*Significance of Flexible Purchase Alternative*	*Significance of Fixed Purchase Alternative*
	Predelivery	Water is delivered early compared to the Baseline Condition.	Increased water levels in reservoirs.	Reservoir surface water elevation would increase compared to the Baseline Condition.	Reservoir surface water elevation would increase compared to the Baseline Condition.	LTS	LTS

In the Upstream from the Delta Region (as well as in the Delta and Export Service Area), under the No Project Alternative, reservoir operations would be same in all year types. Although the amount of water released would differ in wet and dry years, flood control requirements would regulate the reservoirs in the same manner regardless of water year type. Therefore, the effects on flood control would be the same in wet or dry years under the No Project Alternative.

The Fixed Purchase Alternative would be limited to a maximum acquisition of 35,000 acre-feet from all sources of water. This amount could typically be obtained from stored reservoir water purchases in most year types. This acquisition would have a beneficial effect if the purchase were from New Bullards Bar, Little Grass Valley, Sly Creek, Hell Hole, or French Meadows Reservoirs. The effect would be less than significant for the stored reservoir water held in Lake Oroville. Because the Flexible Purchase Alternative could acquire more water than the Fixed Purchase Alternative, and therefore acquire water from multiple reservoirs, there would be a greater potential for beneficial flood control effects with the Flexible Purchase Alternative.

In the Export Service Area, source shifting and predelivery would have the same effects under the Flexible and Fixed Purchase Alternatives. Predelivery would occur more often in wet years when there is greater potential for Delta export. Source shifting, which could create beneficial flood control effects, would occur in years when the low point problem was especially pronounced; source shifting is not directly tied to wet or dry year water types.

15.2.7 Mitigation Measures

There are no potentially significant impacts; therefore, no mitigation is required.

15.2.8 Potentially Significant Unavoidable Impacts

There are no potentially significant unavoidable impacts.

15.2.9 Cumulative Effects

There are no other programs that could store water in Lake Oroville between November and March. If DWR did allow such storage, the lake water surface would

be higher, and flood releases, if needed, would be initiated sooner. Flood control regulations would be followed regardless of the type of water stored in Lake Oroville. Therefore, the cumulative effects would be less than significant

The Sacramento Valley Water Management Agreement, Dry Year Purchase Program, DRRIP, and Central Valley Project Improvement Act Water Acquisition Program, in addition to the EWA, could purchase water through groundwater substitution. The Dry Year Purchase Program, DRRIP, and Central Valley Project Improvement Act Water Acquisition Program, as the well as the EWA, also acquire water through crop idling. Water held in reservoirs during April through June would be released during July through September. Agencies participating in groundwater substitution and crop idling with various programs would cause reservoirs to release more water during July through September than under the Baseline Condition. The USACE flood control guidelines limit releases such that the releases are within channel capacity. Additionally, the releases would be outside the flood season and therefore would not present a risk to flood control. The cumulative effects would be less than significant.

No other water transfer programs are currently managing water that involves early delivery of water, and none are likely to do so. Therefore, there would be no cumulative effects on flood control because of predelivery.

Chapter 16
Power

Hydroelectric facilities are a part of the State Water Project (SWP) and Central Valley Project (CVP) facilities at dams and reservoirs. As water is released from Project reservoirs, the generation facilities produce power that is both used by the Projects and marketed to electric utilities, government and public installations, and commercial customers. Both Projects rely on their hydropower resources to reduce the cost of operations and maintenance and to repay the cost of Project facilities. Hydropower from the Projects is an important renewable energy and comprises approximately 36 percent of the online capacity of California hydroelectric facilities. Overall, CVP/SWP hydroelectric facilities are nearly seven percent of the total online capacity of California power plants.

The SWP uses its power primarily to run the pumps that move SWP water to farmlands and cities, where it can be applied to economically beneficial uses, and to provide peak power to California utilities. SWP long-term power contracts act as exchange agreements with utility companies. These exchange agreements allow the SWP and a utility to integrate the use of their individual power resources in a mutually beneficial manner. In these agreements the SWP provides on-peak energy to the utility in exchange for the return of a greater amount of mid-peak and off-peak energy. The SWP may also receive other compensation in the form of annual monetary payments and/or reduced transmission service rates for SWP facilities served by the utility. Except during surplus conditions in extremely wet years, all SWP power is used for peak power exchange agreements and to operate pumping facilities. In all years, the SWP must purchase additional power to meet pumping requirements.

CVP power is a source of electricity for CVP pumping facilities throughout the Central Valley and Sacramento-San Joaquin Delta, and for many of California's communities. The Western Area Power Administration (Western) sells excess CVP capacity and energy (supplementary to CVP internal needs) to municipal utilities, irrigation districts, and institutions and facilities such as wildlife refuges, schools, prisons, and military bases. Both CVP and SWP sell power at rates designed to recover costs. For the CVP these rates have been slightly below market rates historically. Revenue from Western power sales is an important funding source for the CVP Restoration Fund and for repaying Project debt incurred building the CVP.

EWA actions could change the pattern of power operations at SWP and CVP facilities compared to historical temporal patterns, alter the monthly and hourly (on/off-peak) load at SWP and CVP pumping facilities, affect demand for regional energy resources through increased local groundwater pumping, and affect the economic relationships associated with the temporal changes in SWP/CVP generation and pumping. Generation and groundwater pumping cost effects for non-CVP/SWP facilities (sellers) would be accounted for in the negotiated water price. In addition to these potential electric system effects, capacity and energy demands for increased pumping

could necessitate greater utilization of other power generation methods that may have more environmental effects than SWP/CVP hydroelectric power plants, resulting in indirect environmental effects.

16.1 Area of Analysis

The area of analysis for the evaluation of potential effects upon hydropower generation due to implementation of the Environmental Water Account (EWA) actions includes the power plants, pumping plants and associated facilities located along the SWP and CVP Projects of the Sacramento, Feather, Yuba, American and Merced river systems, as well as those of the Delta Region and Export Service Area. There are no hydroelectric facilities on the mainstem of the San Joaquin River. Also in the area of analysis are reservoirs, powerplants, and pumping plants not owned or operated as part of the SWP or CVP. The specific hydroelectric facilities evaluated are listed below and shown on Figure 16-1. These facilities include power and pumping plants potentially affected by EWA actions, as well as "pass-through facilities," through which EWA water would pass without affecting operations. These details are provided in the individual facility descriptions under Section 16.2, Affected Environment/Existing Conditions.

16.2 Affected Environment/Existing Conditions

16.2.1 CVP Hydropower System

Hydropower generation at CVP facilities substantively contributes to the reliability of California's electrical power system. The CVP hydropower system consists of eight power plants and two pump-generating plants (Table 16-1). This system is fully integrated with the northern California power system and provides a significant portion of the hydropower available for use in northern and central California. The installed capacity of the system is 2,044,350 kilowatts (kW) (USBR 2001). In comparison, the combined capacity of the 368 operational hydroelectric power plants in California is 12,866,000 kW. The area's major power supplier, the Pacific Gas and Electric Company (PG&E), has a generating capacity from all sources of over 20,000,000 kW.

Table 16-1

[1] Not marketed to CVP.
[2] Pump-generating plant.
[3] Jointly owned, pumping and generating facility, Federal share only.
[4]CVP power plants unaffected by EWA actions.

Power produced by the CVP hydropower system first meets Project water pumping loads, or "Project use power," at CVP pumping facilities (Table 16-2). Western markets power that is surplus to Project use as "commercial power" under long-term, firm contracts to municipal and governmental entities (preference customers[1]) at cost-based rates (based on generating/pumping costs). In an average year, preference customers buy 4,600 gigawatt hours (GWh) of energy and 1,700,000 kW of capacity at

[1] Preference customers are those who have contracts subject to the requirements of Reclamation law which provide that preference in the sale of Federal power shall be given to municipalities and other public corporations or agencies and also to cooperatives and other nonprofit organizations financed in whole or in part by loans made pursuant to the Rural Electrification Act of 1936 (Reclamation Project Act of 1939, Section 9(c), 43 U.S.C. 485h(c))

rates that recover the full cost of production and repayment obligations of Project investment with interest (Reclamation 2001). Western has completed and is in the process of implementing its post-2004 Marketing Plan for CVP hydropower resources that are surplus to Project use power needs after the long-term preference customer contracts expire in 2004.

16.2.2 SWP Hydropower System

The primary purpose of the SWP power generation facilities is to meet energy requirements of the SWP pumping plants. To the extent possible, SWP pumping is scheduled during off-peak periods, and energy generation is scheduled during peak periods. Although the SWP uses more energy than it generates from its hydroelectric facilities, the Department of Water Resources (DWR) has exchange agreements with other utility companies and has developed other power resources. DWR sells surplus power, when it is available, to minimize the net cost of pumping energy. DWR first sold excess power commercially in 1968.

The SWP conveys an annual average of about 2.5 million acre-feet (AF) of water through its 17 pumping plants, 8 hydroelectric power plants, 32 storage facilities, and 660-plus miles of aqueduct and pipelines. Affordable hydroelectric generation provides the greatest share of SWP power resources. The combined 900-megawatt (MW) Hyatt Pumping-Generating Plant and Thermalito Pumping-Generating Plant (Hyatt-Thermalito) at Lake Oroville generate about 2,200 GWh of energy in a median water year, while the Thermalito Diversion Dam Power Plant (3,000 kW capacity)[2] adds another 24 GWh of energy per year. Generation at SWP plants, (Gianelli, Alamo, Devil Canyon, Warne, and Mojave Siphon), varies with the amount of water conveyed. These five plants generate about one-sixth of the total energy used by the SWP. The SWP Hydropower and Pumping Plants and their generating capacities are listed in Tables 16-3 and 16-4.

[2] Generating capacities listed in this chapter are installed capacities (the sums of rated capacities of plant generating units).

16.2.3 Other Hydroelectric Facilities

Other hydroelectric generation facilities in the area of analysis are owned by investor-owned utility companies, such as PG&E and Southern California Edison (SCE); by municipal agencies, such as the Sacramento Municipal Utility District (SMUD); and by several agencies. Larger facilities outside the CVP and SWP systems include PG&E's Upper North Fork Feather River System (approximately 340,000 kW capacity) in Plumas County; SMUD's Upper American River Project System (approximately 640,000 kW capacity) in El Dorado County; and the Yuba County Water Agency (YCWA) Yuba River Development Project (approximately 300,000 kW capacity) in Yuba County (CALFED 1999).

16.2.4 Seasonal Variation of Pumping and Generation

During the winter (December through February), Delta export and San Luis Reservoir pumping demands are high until San Luis Reservoir fills. San Luis Reservoir does not

fill every year. Power generation may increase beyond fall levels if flood control operations require additional releases from reservoirs. In a typical year, CVP generation is usually sufficient to satisfy Project use but insufficient to satisfy both Project pumping requirements and preference customer load requirements for the winter months, and Western must purchase additional energy from other sources in the winter. Generation from SWP hydropower facilities and the Reid Gardner coal-fired plant are sufficient to satisfy SWP pumping loads.

During the spring (March through May), exports from the Delta may be limited because San Luis Reservoir is full or because of Delta export limitations; thus, Project-pumping loads may be lower in spring than in winter. The need for late season rainfall and snowmelt flood releases also governs the timing of power generation. Spring is a transitional period for power, as the purchase of additional energy is sometimes, but not always, required for CVP pumping and preference load requirements. Generation from SWP hydropower facilities and the Reid Gardner coal-fired plant are sufficient to satisfy SWP pumping loads.

The system's water demands are highest during the summer (June through August). Releases to meet these demands produce energy at the upstream reservoirs and at the San Luis Reservoir. Although generation at CVP power plants is high because of releases for CVP water demands, pumping loads combined with high preference customer loads frequently require the import of additional energy from the Pacific Northwest. SWP generation at its hydropower facilities is also higher in response to increased releases; however, this generation coupled with Reid Gardner generation is typically insufficient to meet SWP loads. In the summer the SWP relies on its power exchange agreements and energy purchases (primarily from the Pacific Northwest) to meet its remaining energy requirements.

16.2.5 Upstream from the Delta Region

The power facility descriptions included below cover the major power and pumping plants potentially affected by the EWA Program, as well as any "pass-through facilities" through which EWA water would pass without affecting operations (e.g., Edmonston pumping plant, Lake Silverwood, Pyramid Lake). The pass-through facility descriptions are included here to provide representative information on system operations. Sections 16.2.5.1 through 16.2.5.5 present data for the Sacramento, Feather, Yuba, American, and Merced/San Joaquin river systems, respectively.

16.2.5.1 Sacramento River

16.2.5.1.1 Central Valley Project

Shasta

The Shasta Power Plant, constructed in 1944, is a CVP facility at the foot of Shasta Dam on the Sacramento River. Water from the dam is released through the 15-foot-diameter penstocks (power plant intake pipeline) leading to the five main generating units and two station service units. The Shasta Power Plant is a peaking plant - it produces power on a schedule corresponding to peak electrical system usage rather than at a constant rate 24 hours per day. Its power is dedicated first to meeting the requirements of the Project facilities. The plant's installed capacity is 629,000 kW,

and it has an annual average net generation of 2,466 GWh (Reclamation/Placer County Water Agency 2002). The energy remaining after meeting CVP Project use needs is marketed to various preference customers throughout California.

Keswick

The Keswick Power Plant, constructed in 1949, is a CVP facility just below Keswick Dam on the Sacramento River. Unlike Shasta, the Keswick Power Plant runs throughout the day at a constant rate, providing a uniform release to the Sacramento River. The Keswick Power Plant has three generating units with a combined capacity of 117,000 kW and an average annual net generation of 399.3 GWh (Reclamation 2002).

16.2.5.2 Feather River

16.2.5.2.1 South Fork Project

The South Fork Project, covering 82 square miles in three counties, consists of 8 dams, 17 tunnels, 21 miles of canals and conduits, 4 hydroelectric power plants and 21 miles of road. Oroville-Wyandotte Irrigation District (OWID) operates all four hydroelectric power plants (Sly Creek, Woodleaf, Forbestown, and Kelly Ridge), which have a combined generating capacity of more than 100,000 kW (Oroville-Wyandotte Irrigation District 2002b). OWID sells its electricity to PG&E wholesale; in exchange, PG&E pays for the operation and maintenance of the power facilities. OWID has partnered with PG&E since the late 1950s under an agreement that ends in 2009. The South Fork Project provides over 150,000 AF of water storage along with electricity. Although most of the hydropower produced goes to PG&E under contract, OWID also receives cash payments for power produced at its Sly Creek Power Plant.

16.2.5.2.2 Sly Creek

OWID owns the Sly Creek Power Plant located on the central portion of the South Fork Feather River at Sly Creek Reservoir. OWID moves water out of Sly Creek reservoir through the turbine-generator, which has a capacity of 15,000 kW. The generator at Sly Creek Reservoir nets an average 0.5 GWh of monthly generation (Oroville-Wyandotte Irrigation District 2002b).

16.2.5.2.3 Woodleaf

The Woodleaf Power Plant is on the South Fork Feather River just below Sly Creek Reservoir. At Lost Creek, OWID diverts water into the Woodleaf penstock. The Woodleaf Power Plant has a 62,000 kW generating capacity and produces an average of 6.9 GWh of electricity monthly (Oroville-Wyandotte Irrigation District 2002b). OWID moves water from the Woodleaf Power Plant through the Forbestown Diversion Dam.

16.2.5.2.4 Forbestown

The Forbestown Power Plant is on the South Fork Feather River below Ponderosa Dam. OWID transports water to the Forbestown Diversion Dam, then through the Forbestown Tunnel to the Forbestown Power Plant. The power plant has a generating

capacity of 39,000 kW and generates an average of 3.7 GWh monthly (Oroville-Wyandotte Irrigation District 2002b). From the Forbestown powerhouse, the water flows through a series of canals and tunnels into Miners Ranch Reservoir.

16.2.5.2.5 Kelly Ridge

The Kelly Ridge Power Plant, operated by OWID, is near the mouth of the South Fork Feather River. OWID sends water from the Miners Ranch Reservoir into the Kelly Ridge Tunnel, which leads to the power plant penstock. The power plant has a generating capacity of 10,000 kW and produces an average of 3.8 GWh of electricity monthly (Oroville-Wyandotte Irrigation District 2002b).

16.2.5.2.6 State Water Project

Oroville

DWR stores winter and spring runoff in Lake Oroville for release to the Feather River as necessary for Project purposes (water supply, power generation, flood protection, fish and wildlife enhancement, and recreation). These releases generate power at the Hyatt-Thermalito Power Plant Complex.

On a weekly basis, DWR schedules releases to accommodate water supply requirements, water quality and quantity requirements in the Delta, instream flow requirements in the Feather River, power requirements, and flood control. DWR updates this weekly plan as needed to respond to changing conditions.

DWR schedules hourly releases through the Edward Hyatt and Thermalito Pumping Generating plants to maximize the amount of energy produced when power values are highest. Because the downstream water supply is not dependent on hourly releases, and pumping of SWP water can occur at off-peak times; energy prices primarily dictate hourly operations for the power generation facilities.

Storage in Thermalito Forebay and Afterbay helps to maximize the value of Project energy and maintain uniform flows in the Feather River downstream from the Oroville facilities. The Thermalito Afterbay also provides storage for pump-back operations, which are designed to maximize profit from the power generation facilities. DWR releases water from Lake Oroville when power prices are high, then pumps water not needed to meet downstream requirements back into Lake Oroville from Thermalito Forebay and Afterbay when power prices are low. Because DWR operates the power plants to maximize weekday generation when power prices are highest, storage is usually higher in the Afterbay at the end of each week than at the beginning. Downstream releases during the weekend, or pumpback to Lake Oroville (to prepare for the following week's operation) lowers the water in the Afterbay.

16.2.5.3 Yuba River

16.2.5.3.1 Yuba River Development Project

The Yuba River Development Project, constructed by the YCWA, was completed in 1970 and provides flood control protection for Yuba and Sutter Counties, irrigation water for Yuba County agriculture, recreation, and hydropower generation. The

Yuba River Development Project comprises a system of three dams, three tunnels, and four power plants.

Colgate
Colgate Power House is at the convergence of the Middle and North Yuba rivers, at the upstream end of Englebright Reservoir. The Colgate Tunnel follows a path from New Bullards Bar Reservoir about 3 miles to the Colgate Power House. YCWA will operate this facility, which is under contract with PG&E, until 2016. This power plant has a capacity of 315,000 kW (Harper 2001). Average annual generation is 1,314 GWh (Yuba County Water Agency, http://www.ycwa.com/drdat.htm).

Englebright
Narrows Power House I and Narrows Power House II are at the outlet of Englebright Reservoir on the main Yuba River about 2 miles northeast of Smartville (Aikens 2001). PG&E operates the Narrows Power House I, and YCWA operates the Narrows Power House II. Narrows Power House I, with a capacity of 12,000 kW, produces an average 3.8 GWh of electricity monthly and Narrows Power House II, with a capacity of 49,000 kW, produces an average 6.3 GWh of electricity monthly (California Hydropower 1998).

16.2.5.4 American River

16.2.5.4.1 Middle Fork Project

The Middle Fork Project is a multipurpose project that uses the waters of the Middle Fork of the American River, the Rubicon River, and certain tributaries for irrigation, domestic, and commercial purposes and for the generation of electric energy. Principal features of the Middle Fork Project are two storage and five diversion dams, five power plants, diversion and water transmission facilities, five tunnels, and related facilities. The power plants have a combined generating capacity of 247,000 kW and include Hell Hole, French Meadows, Lowell J. Stephenson, Ralston, and Oxbow. The power division of Placer County Water Agency (PCWA) operates the Middle Fork Project.

French Meadows
The French Meadows Power Plant is at Hell Hole Reservoir south of the South Fork of the American River. PCWA diverts water from French Meadows Reservoir through the French Meadows Tunnel. The water passes through the Francis turbine at the power plant, which has a capacity of 15,300 kW (Placer County Water Agency 1967). French Meadows Power Plant generates an average of 5.2 GWh monthly. The water is then held in Hell Hole Reservoir.

Hell Hole
The Hell Hole Power Plant is on the Rubicon River at Hell Hole Reservoir. Water flows from the reservoir through the Hell Hole Dam to the Hell Hole Power Plant. The Hell Hole Power Plant has a capacity of 725 kW (Placer County Water Agency 1967) and generates an average of 0.19 GWh monthly. From the plant, the water flows through a tunnel to the Ralston Afterbay.

Lowell J. Stephenson
The Lowell J. Stephenson Power Plant is on the Middle Fork of the American River at the Middle Fork-Ralston Interbay. Water for the power plant comes from French Meadows Reservoir, through the French Meadows Tunnel, through Hell Hole Reservoir, and finally through the Middle Fork Tunnel. The water passes over the Impulse turbine at the power plant, which has a capacity of 116,100 kW (Placer County Water Agency 1967). The Lowell J. Stephenson Power Plant generates an average of 43.1 GWh monthly. The water flows from the power plant through the Ralston Tunnel.

Ralston
The Ralston Power Plant is on the Rubicon River at the Ralston Afterbay. Water for the Ralston Power Plant follows the same path as the water for the Lowell J. Stephenson Power Plant, through the Ralston Tunnel, to the Ralston Power Plant. The Ralston Power Plant has an Impulse turbine and a capacity of 79,200 kW (Placer County Water Agency 1967). The Ralston Power Plant generates an average of 31.2 GWh monthly. From the plant, the water flows back into the Ralston Tunnel, which continues to the Oxbow Power Plant (below).

Oxbow
The Oxbow Power Plant is on the Middle Fork of the American River at the Oxbow Bar. Water for the Oxbow Power Plant flows from the Ralston Power Plant through the Ralston Tunnel. The plant has a Francis turbine and a capacity of 6,128 kW (Placer County Water Agency 1967). From the power plant, the water continues to the Auburn Ravine and to the lower American River.

16.2.5.4.2 Central Valley Project - Lower American River

Folsom Reservoir and Lake Natoma
The Folsom Power Plant is at the foot of Folsom Dam on the north side of the American River. Its three generating units are tied into the CVP power system through the 20-mile-long Folsom-Elverta 230-kV transmission line. The Nimbus Power Plant is on the right abutment of Nimbus Dam (Lake Natoma) on the north side of the American River. The principal purpose of the Folsom and Nimbus power plants is to generate power using the water releases mandated for downstream appropriators, flood control, fish, and other uses.

The Folsom Power Plant has three generating units, with a combined capacity of 215,000 kW and a combined release capacity of approximately 8,600 cfs (Reclamation 2001). By design, the facility is operated as a peaking facility. Peaking plants schedule the daily water release volume during the peak energy demand hours to maximize generation at the time of greatest need. During other hours of the day, the plant may release little or no water, generating little or no power. The Folsom Power Plant generates an average annual 620 GWh.

To avoid fluctuations in flow in the lower American River, Nimbus Dam and Lake Natoma serve as a regulating facility. While the water surface elevation fluctuates, releases to the lower American River remain constant. The Nimbus Power Plant consists of two generating units with a release capacity of approximately 5,100 cfs

(Reclamation 2001). Electric generation from this facility is continuous throughout the day.

16.2.5.5 Merced/San Joaquin River

16.2.5.5.1 Merced River

Merced Irrigation District's (MID) plants at New Exchequer and McSwain Dams on the Merced River generate power that is sold to utility companies (most recently PG&E), which sell it to consumers. The power plant at the base of Exchequer Dam began operation in June 1926. Since 1967, when the McSwain and New Exchequer Dams were completed, MID has produced nearly 10,000 GWh of electricity, which is an average of nearly 325 GWh a year (Merced Irrigation District 2000). The New Exchequer Power Plant provides electric power to eastern Merced County. Under a long-term contract expiring in 2014, MID also sells electricity generated at its New Exchequer Power Plant to PG&E, for its customers in Northern California.

16.2.5.5.2 Exchequer

The Exchequer Power Plant is on the Merced River below Exchequer Dam. The plant has a capacity of 80,100 kW and an average monthly energy production of 26.3 GWh.

16.2.5.5.3 McSwain

The McSwain Power Plant is on the Merced River below McSwain Dam. The plant has a capacity of 9,000 kW and an average monthly energy production of 3.75 GWh.

16.2.5.5.4 San Joaquin River

No hydroelectric facilities are on the mainstem of the San Joaquin River.

16.2.6 Sacramento-San Joaquin Delta Region

The Delta facilities do not operate to generate power supply; instead, they consume large quantities of energy. Among the Delta facilities that need power to operate are the Tracy and Harvey O. Banks Pumping Plants, described below.

16.2.6.1 Central Valley Project

16.2.6.1.1 Tracy Pumping Plant

The U.S. Bureau of Reclamation (Reclamation) completed the Tracy Pumping Plant in 1951. The Tracy facilities include an inlet channel, pumping plant, and discharge pipes. The pumping plant lifts water 197 feet from the Delta into the Delta-Mendota Canal. Each of the six pumps at Tracy is powered by a 22,500-horsepower motor and is capable of pumping 767 cfs (Reclamation 2001). CVP power plants supply power to run the pumps. The water is pumped through three 15-foot-diameter discharge pipes and carried about 1 mile up to the Delta-Mendota Canal. The intake canal includes the Tracy Fish Screen, which was built to intercept downstream migrant fish so they may be returned to the main channel. The Tracy Pumping Plant is a "pass-through" facility relative to this analysis.

16.2.6.2 State Water Project

16.2.6.2.1 Harvey O. Banks Pumping Plant

The Harvey O. Banks Pumping Plant is on the southern edge of the Delta and can lift 21,000 AF/day of water 224 feet into the California Aqueduct. The Clifton Court Forebay, which precedes the Banks Pumping Plant, provides storage and regulation of flows into the Banks Pumping Plant. The construction of Banks Pumping Plant was completed in 1963, with seven pump units and a total pumping capacity of 6,400 cfs. In 1986, four additional pumps were installed in the plant, increasing its capacity to 10,670 cfs (California Department of Water Resources 2002). The Harvey O. Banks Pumping Plant is a "pass-through" facility relative to this analysis.

16.2.7 Export Service Area

16.2.7.1 Central Valley Project

16.2.7.1.1 O'Neill Pumping-Generating Plant

O'Neill Pumping-Generating Plant is on the Delta Mendota Canal in Merced County, 70 miles from the Tracy Pumping Plant and 12 miles west of Los Banos. O'Neill Dam and Forebay are joint Federal/State facilities on the San Luis Creek, 2.5 miles downstream from San Luis Dam. The O'Neill Pumping-Generating Plant is a conventional plant consisting of an intake channel leading off the Delta-Mendota Canal and six pump-generating units. Normally, these units operate as pumps to lift water 45 to 53 feet into the O'Neill Forebay. The forebay also releases water to the Delta-Mendota Canal. During releases to the Delta-Mendota Canal, the O'Neill plant generates electricity. When operating as pumps and motors, each unit, with a 6,000 horsepower motor, can discharge 700 cfs. When operating as turbines and generators, each unit has a generating capacity of about 4,200 kW (Reclamation 2001). The authorizing legislation for the plant states that power generated at the facility cannot be used for commercial purposes. O'Neill Forebay is a joint State and Federal facility, but O'Neill Pumping-Generating Plant only moves CVP water between the CVP Delta-Mendota Canal and O'Neill Forebay. No State water goes through the plant because the California Aqueduct flows by gravity into O'Neill Forebay.

16.2.7.2 Joint Central Valley Project/State Water Project

16.2.7.2.1 San Luis Reservoir

The State of California operates and maintains the William R. Gianelli Pumping Plant (formerly the San Luis Pumping Plant) under an agreement with Reclamation. The plant is in Merced County, on the San Luis Creek, 12 miles west of Los Banos. This joint Federal/State facility, at San Luis Dam, lifts water with pump turbines from the O'Neill Forebay into the San Luis Reservoir. During the irrigation season, water released from San Luis Reservoir generates energy as it flows back through the pump turbines to the forebay. Each of the eight pumping-generating units has a 63,000-horsepower motor and a capacity of 53,000 kW as a generator (Reclamation 2001). As a pumping plant to fill San Luis Reservoir, each unit lifts 1,375 cfs at a design dynamic head of 290. As a generating plant, each unit passes 2,120 cfs at a design dynamic head of 197 feet. The plant pumps CVP and SWP water for offstream storage.

16.2.7.2.2 Dos Amigos Pumping Plant

This joint Federal/State facility, 17 miles south of the forebay, is a relift plant in the San Luis Canal. The plant contains six pumping units, each with a 40,000-horsepower motor, capable of delivering 2,200 cfs at 125 feet of head (Reclamation 2001). The Dos Amigos Pumping Plant is a "pass-through" facility relative to this analysis.

16.2.7.3 State Water Project

16.2.7.3.1 Buena Vista Pumping Plant

Buena Vista Pumping Plant is located on the California Aqueduct about 24 miles southwest of Bakersfield in Kern County. The plant has an installed capacity of about 5,400 cfs and lifts water from about elevation 295 feet to 500 feet.

16.2.7.3.2 Teerink Pumping Plant

The John R. Teerink Wheeler Ridge Pumping Plant is located on the California Aqueduct about 27 miles downstream from the Buena Vista Pumping Plant. This plant lifts water from about elevation 492 feet to 725 feet.

16.2.7.3.3 Chrisman Pumping Plant

The Ira J. Chrisman Wind Gap Pumping Plant is located on the California Aqueduct about 1.6 miles downstream from the Teerink Pumping Plant. The plant lifts water approximately 515 feet.

16.2.7.3.4 Edmonston Pumping Plant

Water enters into the Edmonston Pumping Plant from the California Aqueduct. The Edmonston Pumping Plant lifts water 1,926 feet (the highest single lift in the world) to enter 8.5 miles of tunnels crossing the Tehachapi Mountains. From this point the water continues south through Quail Lake, Pyramid Lake, and finally to Castaic Lake. The Edmonston Pumping Plant has 14 pump units with a total plant capacity of 4,480 cfs (Castaic Lake Water Agency 2002). The Edmonston Pumping Plant is a "pass-through" facility relative to this analysis.

16.2.7.3.5 Pyramid Lake

The DWR owns and operates the William E. Warne power plant. Located on the Gorman Creek arm of Pyramid Lake, the power plant helps meet the SWP need for electricity. This plant has an installed capacity of 78,000 kW and generates up to 358 GWh a year (California Department of Water Resources 1997). Water flowing from Pyramid Lake through the 7.5-mile-long Angeles Tunnel spins the turbines in the Castaic Power Plant.

16.2.7.3.6 Castaic Power Plant

Elderberry Forebay, a small reservoir separated from Castaic Lake by Elderberry Forebay Dam, is at the upper end of Castaic Lake and provides regulating storage for the Castaic Power Plant. The Castaic Power Plant generates electricity during on-peak periods (weekday daylight hours) when extra power is needed in the Los Angeles area. During off-peak periods (nights and Sundays) when local power is less costly, the plant pumps water back into Pyramid Lake. This operation also reduces the cost

of power required to move SWP water from Northern to Southern California. Castaic Power Plant is a cooperative venture of DWR and the City of Los Angeles Department of Water and Power.

16.2.7.3.7 Silverwood Lake

Water reaches Silverwood Lake from the East Branch of the California Aqueduct. The Pearblossom Pumping Plant east of Palmdale pumps the water 542 feet from the Antelope Valley floor to an elevation of 3,479 feet. Flowing downhill through an open aqueduct, the water is then piped under the Mojave River bed through the 29.4 megawatt Mojave Siphon Power Plant and into Silverwood Lake (California Department of Water Resources 1997). Water released from the south end of Lake Silverwood flows through the 3.8-mile San Bernardino Tunnel, plunges 1,400 feet into Devil Canyon Power Plant, and then flows into Lake Perris via the Santa Ana Valley pipeline. These are "pass-through" facilities relative to this analysis.

16.2.7.4 Non-Project

16.2.7.4.1 Diamond Valley Lake

Diamond Valley Lake is located approximately four miles southwest of the City of Hemet and completed filling in December 2002. Water for the reservoir comes from the Colorado River Aqueduct, delivered through the San Diego Canal into the reservoir forebay and from the SWP via Lake Silverwood. This reservoir has a pumping plant consisting of twelve pumps, each with a 5,000-horsepower motor. The facilities also include a 1,000 cubic foot per second hydrologic control structure at the Colorado River Aqueduct (Temecula Valley 2000). Of the 12 pumps, four have been converted to pumping–generating units with a unit capacity of 3,000 kW. Additional pumps are planned for conversion at a later date. The Hiram W. Wadsworth Pumping Plant is a "pass-through" facility relative to this analysis.

16.2.8 Regulatory Setting

Western is the marketing agency for power generated at Reclamation's CVP facilities. Created in 1977 under the Department of Energy (DOE) Organization Act, Western markets and transmits electric power throughout 15 western states. Western's Sierra Nevada Customer Service Region (Sierra Nevada Region) annually markets approximately 8,000,000 kilowatthours (kWh), including 3,000,000 kWh produced by CVP generation and 5,000,000 kWh produced by other sources.

Western's mission is to sell and deliver electricity that is excess to Project use (power required for CVP Project operations). Western's power marketing responsibility includes managing the Federal transmission system and, as a Federal agency, ensuring that operations of the hydropower facilities are consistent with its regulatory responsibilities. Specifically, Western's capacity and energy sales must be in conformance with the laws that govern its sale of electrical power. The hydroelectric generation facilities of the CVP are operated by Reclamation. Reclamation manages and releases water in accordance with the various acts authorizing specific projects and in accordance with other laws and enabling legislation. Hydropower operations at each facility must comply with minimum and maximum flows and other

constraints set by Reclamation, U.S. Fish and Wildlife Service (USFWS), or other regulatory agencies, acting in accordance with law or policy.

Existing contracts for the sale of Sierra Nevada Region power resources expire December 31, 2004. Western has developed a marketing plan that defines the products to be offered and the eligibility and allocation criteria that would lead to allocations of CVP electric power resources beyond the year 2004.

16.3 Environmental Consequences/Environmental Impacts

16.3.1 Assessment Methods

The monthly gross CVP and SWP electrical generation and capacity for the various conditions simulated in this study were estimated using results from a CALSIM II simulation, utilizing several data post-processing tools. Assessment methods are described in detail in Attachment 1, Modeling Description. Differences in generation and capacity between alternative conditions were then evaluated to assess effects. Also evaluated were differences in the amount of energy needed to pump water at the Project pumping plants.

16.3.2 Significance Criteria

16.3.2.1 Hydropower

EWA actions would result in a potentially significant adverse effect on hydropower production if generation at affected facilities were substantially reduced. An effect on hydropower production was considered potentially significant if implementing an EWA action would cause:

- A decrease in surface-water elevations beyond optimum efficient levels in reservoirs within the area of analysis that would decrease the efficiency of the power generation facilities. Decreased efficiency would cause the power plant to produce less energy with the same amount of water release.

- A change in timing of reservoir releases, which could shift generation to a time of year when power has lower value. The value for power varies by season, typically with lower prices in the spring and somewhat higher prices in the late summer and early fall. The current open power market, however, is less predictable and may not follow this traditional pattern. Therefore, any change in timing is considered potentially significant.

Reduction in CVP/SWP generation could be a cost effect either because the entities would be precluded from selling excess energy or might be required to purchase additional energy for their own or customer's loads. Similarly, if capacity was reduced relative to the Baseline Condition, then a cost effect could be incurred.

16.3.2.1.1 Pumping Load

EWA actions would result in a potentially significant adverse impact on power if the timing of pumping was changed, or if energy consumed by the pumps would be substantially increased. An effect on power was considered potentially significant if implementing an action would cause:

- A change in timing of pumping, which could shift the load to a time of year when power has higher costs. Because of the uncertainty of the open power market, any change in timing is considered potentially significant.

- An increase in pumping energy requirements for purveyors who withdraw water from reservoirs. The energy requirements would increase if the reservoir levels decrease as a result of the EWA.

16.3.3 Environmental Consequences/Environmental Impacts of the No Action/No Project Alternative

The No Action/No Project alternative reflects the condition for CVP/SWP power production should the EWA water acquisition strategy not be implemented. Releases and storage of EWA asset water would change the timing of generation at some facilities. Without the EWA water purchases, the Project power facilities would operate as under the affected environment/existing conditions setting. Under No Action/No Project, there would be no changes in CVP/SWP power production or usage, no new power facilities constructed/operated, and no facilities would be taken off-line because there would be no EWA. Therefore, no effects would be associated with the No Action/No Project Alternative.

As described in Section 3.4, the California Environmental Quality Act (CEQA) basis of comparison is the Affected Environment. The National Environmental Policy Act (NEPA) basis of comparison is the Future Conditions Without the Project. As described in the above paragraph, the Affected Environment and the Future Conditions Without the Project (No Action/No Project Alternative) are the same; therefore, they are collectively referred to as the Baseline Condition in the following sections.

16.3.4 Environmental Consequences/Environmental Impacts of the Flexible Purchase Alternative

For power resources, the environmental consequences of utilizing stored reservoir water, groundwater substitution, and crop idling vary by the specific water bodies affected, as discussed below. Environmental consequences of source shifting do not vary substantially by location; therefore, the effect analysis is grouped by acquisition type. In those cases where no environmental consequences to power resources have been associated with an acquisition type, the acquisition type is not discussed. All changes to surface-water elevations and flows are in comparison to the Baseline Condition. Only those power facilities that have the potential to be affected by the EWA Program are included below. The analysis of the Flexible Purchase Alternative

incorporates implementation of the Variable Assets described in Attachment 1, Modeling Description.

16.3.4.1 Upstream from the Delta Region

16.3.4.1.1 Sacramento River

EWA agencies' acquisition of Sacramento River Contractor water via groundwater substitution or crop idling would cause changes in the release pattern from Lake Shasta in June through September. EWA transfer water from idling or groundwater substitution could be temporarily stored in Lake Shasta and then released during July through September. The EWA would not change the amount of water that is released from Lake Shasta, but would alter the release pattern. Lake Shasta surface water elevation likely would be slightly lower than the Baseline Condition because of "borrowing" of Shasta storage for July pumping of EWA water prior to August/September crop idling water being available; reduced head (on average less than 0.3 foot) would therefore slightly decrease the head component of generation efficiency. Changes in the release patterns to facilitate pumping of EWA water of the crop idling water also alter the monthly generation efficiency; however, average annual Shasta/Keswick generation is insignificantly decreased by only 263 kWh (Table 16-5). As stated previously, the value of power fluctuates throughout the year. Typically, prices are higher in late summer and fall and lower in the spring. Groundwater substitution would have no effect on Shasta/Keswick generation, and crop-idling would create slightly increased generation in July and slightly less generation in August and September compared to the Baseline Condition. However, in an open market, seasonal price fluctuations may not always reflect the norm. These effects could be potentially significant. Mitigation measures listed in Section 16.3.9 would reduce these potentially significant effects on power production and energy to less than significant.

Table 16-5
Shasta/Keswick Average Monthly Generation (kWh)

	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Total
Baseline	193,762	227,992	210,737	203,075	230,313	265,015	306,337	237,885	147,652	131,929	111,254	161,237	2,427,188
FPA	193,762	227,992	210,737	203,075	230,313	265,015	308,873	236,328	146,410	131,929	111,254	161,237	2,426,924

FPA – Flexible Purchase Alternative

16.3.4.1.2 Feather River

Lake Oroville

EWA agencies' acquisition of Feather River Contractor water via groundwater substitution or crop idling would decrease the releases from Lake Oroville in May and June. Water acquired by the EWA agencies would be held in Lake Oroville in May and June and released during July through September. An increase in surface elevation compared to the Baseline Condition would increase the head and therefore the efficiency of power generation during May and June. Decreases in releases during May and June and pattern changes for July through September in response to pumping EWA water will temporally alter generation (Table 16-6). However, on an average annual basis, Oroville/Thermalito generation will increase by about 2,800 kWh.

Table 16-6
Oroville/Thermalito Average Monthly Generation (kWh)[(1)]

	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Total
Baseline	174,284	202,551	216,738	201,680	248,429	305,033	295,319	251,909	120,963	97,946	80,266	139,954	2,335,071
FPA	176,165	202,851	216,856	199,946	238,885	292,568	323,923	254,344	114,009	97,946	80,266	140,122	2,337,881
Difference	1,881	300	118	(1,734)	(9,543)	(12,465)	28,605	2,435	(6,954)	0	0	168	2,810

FPA – Flexible Purchase Alternative
(1) Thermalito pumpback operations not included

Effects related to the value of power generated later in the summer could be potentially significant. Mitigation measures listed in Section 16.3.9 would reduce these potentially significant effects on power production and energy to less than significant.

EWA agencies' acquisition of stored reservoir water would include release of water from Sly Creek and Little Grass Valley Reservoirs in November to be held in Lake Oroville until the following summer. This water would increase the head component of generation efficiency, creating slightly higher generation at Oroville in the November through April period, assuming that the water is not spilled by flood operations. Sly Creek and Little Grass Valley Reservoirs may refill during the winter and spring, potentially holding water that belongs to the CVP/SWP. If that water were owed to the Projects, it would be repaid the following summer. Refill by Sly Creek and Little Grass Valley Reservoirs would only capture up to the amount released in November to Lake Oroville. Therefore, Lake Oroville already would contain as much or more water than it is foregoing due to refill of Sly Creek and Little Grass Valley Reservoirs. Thus, there would be no effects on power production and energy from EWA acquisition of stored reservoir water from Little Grass Valley and Sly Creek.

16.3.4.1.3 Yuba River

EWA agencies' acquisition of YCWA stored reservoir water would result in releases from New Bullards Bar Reservoir in July, August, and September. The water released in July through September would produce increased power production compared to the Baseline Condition. Increased flows through Narrows Power House I and Narrows Power House II, downstream from New Bullards Bar Reservoir, would allow PG&E to produce more power. This is a potentially beneficial effect on power production and energy.

EWA agencies acquisition of water through groundwater substitution would decrease New Bullards Bar releases in April through June. Power generation along the Yuba River would be decreased while water was held in New Bullards Bar Reservoir and increased when released between July and September. Effects would be similar to those described above for groundwater substitution on the Sacramento and Feather Rivers. Effects related to the value of power generated later in the summer could be potentially significant. Mitigation measures listed in Section 16.3.9 would reduce these potentially significant effects on power production and energy to less than significant.

16.3.4.1.4 American River

French Meadows and Hell Hole Reservoirs

EWA agencies' acquisition of PCWA stored reservoir water would result in releases from French Meadows and Hell Hole reservoirs in July, August, and September. The water released in July through September would generate increased power production relative to the Baseline Condition. Increased flows through the French Meadows and Hell Hole Power plants would allow PG&E to produce more power. This is a potentially beneficial effect on power production and energy.

Folsom Reservoir and Lake Natoma

EWA agencies' acquisition of Sacramento Groundwater Authority's stored groundwater and upstream stored reservoir water would change water levels in the reservoir during summer. Groundwater purchases, which are estimated to be small in magnitude, would be held in Folsom Reservoir until the time of EWA use, thereby increasing storage in Folsom. Increased generation would be available with this water, as it is presently being used upstream from Folsom Dam.

Upstream stored water purchases likely would take place over the July through September period, but some portion likely would be used for pumping EWA water in advance of upstream releases. This advanced use would require a "borrowing" of CVP storage in Folsom Reservoir during early summer, with payback completed by the end of September. Studies show that typically (72-year period of record), increased releases from Folsom Reservoir for pumping EWA water can cause a reduction in storage during July and August. Although storage is lower in these months, the increased release for pumping EWA water during July and August creates an increase in Folsom/Nimbus generation of about 2,600 kWh. During September there is decreased generation associated with the reduction in head (storage) at the beginning of the month; however, the additional release for pumping EWA water results in more generation, about 150 kWh, creating an increase in annual generation of 2,760 kWh *(*Table 16-7*)*. If upstream water purchases were completed prior to July, an increase in surface elevation compared to the Baseline Condition would increase the head and thus likely increase the efficiency of power generation, thereby creating an even greater net generation benefit at Folsom.

Table 16-7
Folsom/Nimbus Average Monthly Generation (kWh)

	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Total
Baseline	70,534	76,780	69,458	65,509	73,438	77,230	75,421	45,465	49,251	29,517	41,982	59,709	734,295
FPA	70,534	76,780	69,458	65,509	73,438	77,230	77,259	46,235	49,403	29,517	41,982	59,709	737,055
Difference	0	0	0	0	0	0	1,838	770	152	0	0	0	2,760

FPA – Flexible Purchase Alternative

Upstream reservoirs would refill during the wet season under normal refill conditions and would be full at the beginning of the following season, thus resulting in no adverse power effects. During refill, however, the upstream reservoirs may utilize Project water. The water use would be calculated after the refill is complete. The water would then be slowly released from the upstream reservoirs during the late summer into Folsom Reservoir. During this time, Folsom Reservoir would have

lower elevations relative to the Baseline Condition, which would decrease the efficiency of power generation.

As described above for the Sacramento River, altering water release (power production) could produce positive or negative effects. EWA activities could temporally shift hydropower generation. This may result in a shift of generation from on-peak to off-peak periods, resulting in generation of lower economic value. In addition, the changes in water levels in Folsom Reservoir would alter the power needs for those agencies that pump directly out of the reservoir, which could potentially cause effects. Because the elevation differences are small, on average 0.4 foot or less, there would be little effect.

Effects related to the economic value of power generated or additional pumping costs experienced by agencies pumping water from Folsom Reservoir could be potentially significant. Mitigation measures listed in Section 16.3.9 would reduce these potentially significant effects on power production and energy to less than significant.

Lake Natoma
EWA agencies' acquisition of American River Contractor water via groundwater purchase and upstream stored reservoir water purchase would increase flows through Nimbus Power Plant during summer and fall months. Generation at Lake Natoma is solely dependent upon flow, thus generation would increase. Therefore, the effects on power production would be considered less than significant.

16.3.4.1.5 Merced River

New Exchequer
EWA agencies' acquisition of Merced River Contractor water via groundwater substitution or crop idling would decrease the releases from New Exchequer and McSwain Dams from April through September. Water acquired by the EWA agencies would be held in New Exchequer Reservoir during the irrigation season and released during October through December. Fewer releases from April through September would result in less generation during that period. However, the increase in surface elevation during the summer months compared to the Baseline Condition would increase the head and therefore the efficiency of power generation. As described above for the Sacramento River, delaying water release (power production) until the fall could produce beneficial effects. Effects related to the value of power generated later in the fall could be potentially significant. Mitigation measures listed in Section 16.3.9 would reduce these potentially significant effects on power production and energy to less than significant.

McSwain Dam
EWA agencies acquisition of Merced River Contractor water via groundwater substitution or crop idling would decrease the releases from McSwain Dam during the irrigation season. Power production at McSwain is regulated at the dam's gates and is minimally reliant on head. Decreased flows from McSwain would decrease energy generation. Effects related to the value of power generated later in the fall could be potentially significant. Mitigation measures listed in Section 16.3.9 would reduce these potentially significant effects on power production and energy to less than significant.

16.3.4.2 Delta Region

16.3.4.2.1 Pumping Energy Cost Effects of the Flexible Purchase Alternative

The EWA Program would shift a portion of CVP and SWP Delta exports from December through June, to July through September, based on the timing of EWA fish actions and on replacement pumping. This would shift export pumping to the summer when recent information shows that electricity costs are greater.

Modeling of pumping operations under the Baseline Condition was conducted using CALSIMII. As described in Attachment 1, pumping operations reflecting EWA actions are not readily identifiable over the 70-year period of record; however, a 15-year period of record (1979 – 93) were developed for Delta fisheries and water quality analyses (see Attachment 1) reflecting two potential EWA scenarios, water acquisition at 600 TAF and a "Typical" water purchase scenario at between 200 and 300 TAF (refer to Section 2.4.3). These two 15-year scenarios are compared to the Baseline Condition using the post-processor tools to estimate the change in electricity use and associated economic cost.

Figure 16-2 shows the average combined monthly electricity usage at Tracy, O'Neill, and Banks Pumping Plants under the Baseline Condition and under the 600 TAF acquisition (Maximum Water Purchase) scenario. Electricity usage was calculated as 297 kWh/af for Banks pumping and 298 kWh/acre foot for the Tracy/O'Neill pumping. Relative to the Baseline, there are no pumping changes October through November, but there are decreases in Flexible Purchase Alternative pumping December through June in response to EWA fish actions and increases in Flexible Purchase Alternative pumping July through September for makeup pumping. Figure 16-3 shows a similar pumping pattern for the Baseline Condition and the "Typical" Water Purchase Scenario.

The amount of energy required to pump an acre-foot of water from the Delta does not vary during the year; however, the cost of electrical energy does vary from month to month. An estimate of export pumping costs must be made both in energy and dollars to fully analyze the effects of the Flexible Purchase Alternative. To do so requires data on the patterns of export pumping and energy costs.

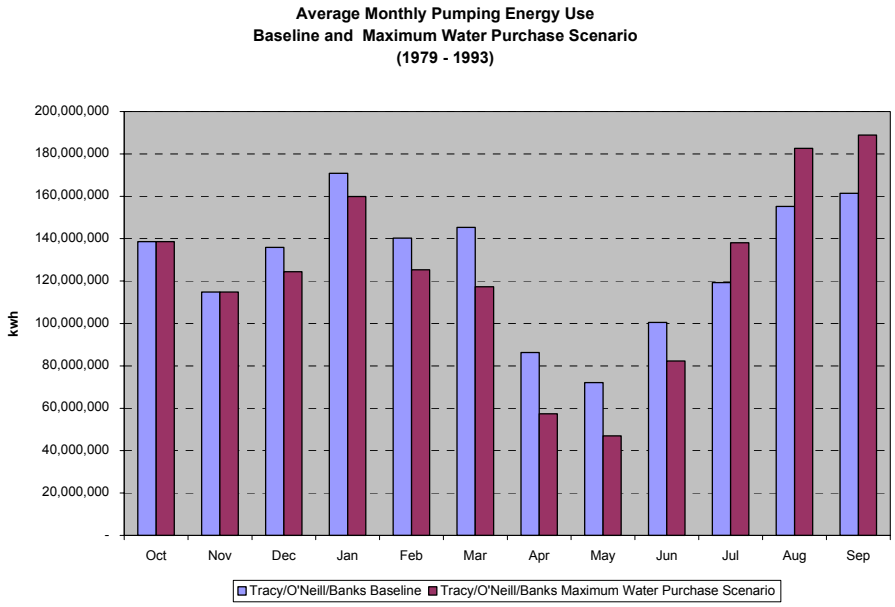

Figure 16-2
Average Monthly Pumping Load at Banks and Tracy/O'Neill Pumping Plants for Baseline and EWA at 600 TAF, 1979-93 Study Period of Record

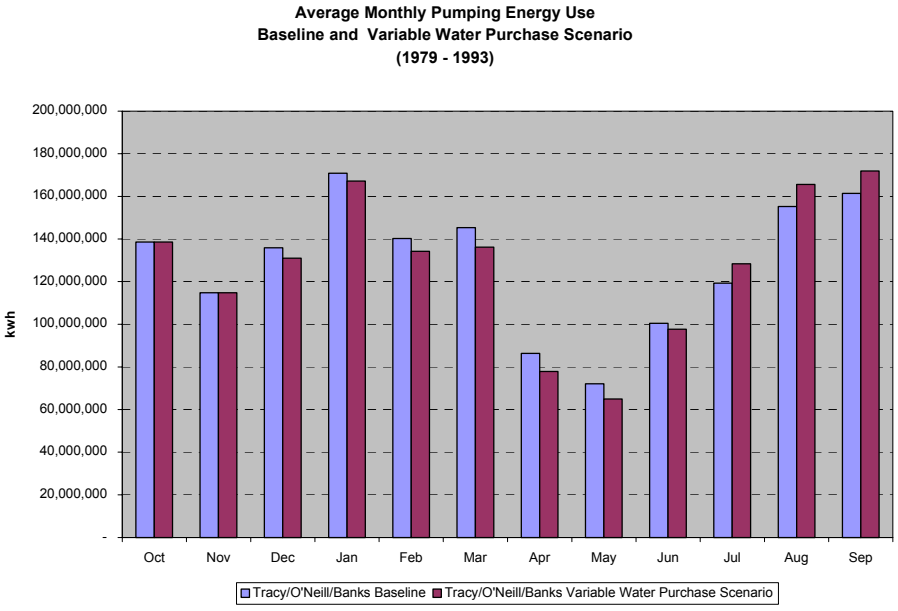

Figure 16-3
Average Monthly Pumping Load at Banks and Tracy/O'Neill Pumping Plants For Baseline and Typical EWA Scenario, 1979-93 Study Period of Record

Table 16-8 contains simulation data for monthly average Delta export pumping and estimated year 2005 on-peak electricity rates. The California Energy Commission "2002 – 2012 Electricity Outlook Report" dated February 2002 projects monthly average peak spot prices for 2005 in the $27 to $39/MWh range (Table 16-8). (See [Figure II-2-4] at http://www.energy.ca.gov/reports/2002-06-10_700-01-004F.PDF).

The monthly export data are used to calculate the energy results shown in Figures 16-2 and 16-3. It is notable that the total export pumping in the Flexible Purchase Alternative does not match the baseline total. This condition occurs when, in the 15-year studies, hydrology or operational constraints affect replacement pumping (see Attachment 1 for additional explanation for each year). For the purposes of this analysis, it is assumed that annual exports should be equal for the Baseline and Flexible Purchase Alternative; therefore, the water volume, labeled as Difference Water in Table 16-8, is assumed to be pumped sometime during the July through September period, which maximizes the energy costs of the scenarios.

Table 16-9 presents the estimated export pumping costs for the Baseline and Flexible Purchase Alternative. During the October through June months, export pumping is reduced by EWA actions and this is reflected by the lower average monthly pumping costs in the Flexible Purchase Alternative, compared to the Baseline Condition. Conversely, when replacement pumping occurs during the July through September months, pumping costs are higher with the Flexible Purchase Alternative.

Summing the entire year, and adding the additional cost of pumping the Difference Water, the water acquisitions at 600 TAF creates an additional average annual export pumping cost of $263,671. Analysis of the individual 15 years shows that the annual cost ranges between $525,000 and a savings of $6,000.

Summing the entire year, and adding the additional cost of for pumping the Difference Water, the Typical Water Purchase Scenario creates an additional average annual export pumping cost of $360,690. Analysis of the individual 15 years shows that the annual cost ranges between $1,665,000 and a savings of $950,000.

16.3.4.2.2 Pumping Energy Cost Effects of the Fixed Purchase Alternative

The Fixed Purchase Alternative described in Chapter 2 was not quantitatively analyzed in the EIS/EIR for each year of the modeled period of record. As is discussed in the resource areas, the Flexible Purchase Alternative scenarios with as much as 600 TAF of exports, impose a much larger burden on upstream release and Delta export facilities, and are more demanding of operational adjustments by the SWP and CVP than a 185 TAF project with only 35 TAF originating in the Upstream from the Delta Region.

In the worst case, assuming that all of the 35 TAF upstream from the Delta purchased is pumped in the least favorable time with respect to power prices, and, that the offsetting pumping curtailments occur at the time of lowest power prices, the cost differential of the 35 TAF would be about $73,000. Subtract from this $73,000 the savings associated with the other 150 TAF (185 – 35 = 150) of pumping foregone by EWA water purchases south of the Delta which do not need to be exported, there is a net power benefit. Assuming that the foregone pumping is 150 TAF, at a pumping energy rate of 298 kWh/AF, and a cost of $27.00/MWh, the annual savings are $1,205,000; creating an annual net benefit of $1,132,000 ($1,205,000 - $73,000 = $1,132,000).

16.3.5 Regional Water Purchase Areas

16.3.5.1 Effect of the Flexible Purchase Alternative on the Regional Electricity Market

The Flexible Purchase Alternative could affect the regional electricity market; although it is not anticipated to have a significant effect on generation from CVP or SWP hydroelectric power plants (see previous discussion in this chapter). However, the shift in timing of Delta exports would increase electric power demand during July, August, and September, the three months of the year with the smallest projected surplus in the California electricity market. The California Energy Commission "2002 Monthly Electricity Forecast: California Supply Demand Capacity Balances for May – December" projects a surplus of 3,400,000 to 3,900,000 kW per month for the July through September period ([Table 16-5] in http://www.energy.ca.gov/reports/700-02-003F/2002-05-10_700-02-003F.PDF). This projection applies to statewide electricity supplies and demands. The amount of supply in excess of demand would probably be less in the northern California region.

Shifting the timing of pumping also may shift the energy use from off-peak hours in the spring to on-peak hours during the summer at the export facilities. This shift from off- to on-peak is a potential problem from an economic standpoint because of the price differential between on- and off-peak power. Also, to the extent that additional on-peak load will be present, California's electrical capacity available during the most critical time of the year will be diminished. On some days it may be necessary to curtail EWA water purchase pumping in response to electrical system emergencies. In addition, discontinuation of the Western-PG&E contract could result in Independent System Operator scheduling costs for the CVP. During the term of the Western-PG&E contract, PG&E has carried the costs of scheduling CVP loads and likely could readily absorb fluctuations in CVP power operations within its much larger system. However, Reclamation/Western will become responsible for the timely declaration of loads and resources after 2004. To the extent that conveyance of EWA water purchases and EWA actions affect day-to-day CVP power scheduling, there may be additional costs borne by the CVP. These effects could be potentially significant. Mitigation measures listed in Section 16.3.9 would reduce these potentially significant effects on power production and energy to less than significant.

16.3.5.1.1 EWA at 600 TAF Acquisitions (Maximum Water Purchase) Scenario

The EWA at 600 TAF would result in an average electricity increase of about 45,900,000 kWh per month at the Project pumps during July, August, and September. In addition, groundwater wells in the Sacramento Valley would increase their use of electricity for water supply replacement. The increased use of electricity by groundwater wells can be estimated in comparison to the incremental power consumed by the Project pumps. At most, the incremental amount of groundwater pumped by the wells would be 200 thousand acre-feet (TAF), which is the maximum volume thought to be available for purchase north of the Delta. The lift would be about one-eighth of the Delta lift; thus, an estimate of 36 kWh/af is assumed as the energy cost. This is based on an average groundwater lift of 30 feet compared to the

Project pumps lift of about 250 feet. Therefore, the groundwater wells, in aggregate, could increase electricity use by at most 7,200,000 kWh (200,000 af * 36 kWh/af = 7,200,000 kWh) or 2,400,000 kWh per month during these three months.

In total, EWA at 600 TAF is estimated additional July through September export pumping could increase electricity use by 45,900,000 kWh and groundwater wells could increase regional electricity use by 2,400,000 kWh for a combined average of 48,300,000 kWh per month. Assuming 24-hour operation throughout the month, the increased power demand would be 66,350 kW. This represents less than 2 percent of the projected statewide electrical surplus during these months.

16.3.5.1.2 Typical Water Purchase Scenario

The Typical Water Purchase Scenario would result in an average electricity increase of about 34,300,000 kWh per month at the Project pumps during July, August, and September. In addition, groundwater wells in the Sacramento Valley would increase their use of electricity for water supply replacement. The increased use of electricity by groundwater wells can be estimated in comparison to the incremental power consumed by the Project pumps. At most, the incremental amount of groundwater pumped by the wells would be 200 TAF, which is the maximum volume thought to be available for purchase north of the Delta. The lift would be about one-eighth of the Delta lift; thus, an estimate of 36 kWh/af is assumed as the energy cost. This is based on an average groundwater lift of 30 feet compared to the Project pumps lift of about 250 feet. Therefore, the groundwater wells, in aggregate, could increase electricity use by at most 7,200,000 kWh (200,000 af * 36 kWh/af = 7,200,000 kWh) or 2,400,000 kWh per month during these three months.

In total, the Typical Water Purchase Scenario is estimated additional July through September export pumping could increase electricity use by 34,300,000 kWh, and groundwater wells could increase regional electricity use by 2,400,000 kWh for a combined average of 36,700,000 kWh per month. Assuming 24-hour operation throughout the month, the increased power demand would be 49,850 kW. This represents about one and one-half percent of the projected statewide electrical surplus during these months.

16.3.6 Export Service Area

16.3.6.1 San Luis Reservoir

EWA export pumping restrictions in the spring would place an additional burden on San Luis Reservoir for meeting south of Delta water demands prior to EWA water purchases in the summer. As a consequence, San Luis Reservoir storage and water-surface elevations from April until September would be lower. From April through June, San Luis Reservoir releases would be slightly higher and generation would be slightly greater than under the Baseline Condition. From July through September, San Luis releases would be reduced, relative to the Baseline Condition, when EWA water purchases are made available from the Delta. As a result of reduced reservoir releases, generation at San Luis for this period would be less than that in the Baseline Condition.

Although the annual San Luis generation would be little changed, the change in generation from summer to spring could have an economic effect on power operations because of temporal price differences. These effects could be potentially significant. Mitigation measures listed in Section 16.3.9 would reduce these potentially significant effects on power production and energy to less than significant.

EWA agencies' acquisition of water via source shifting would delay deliveries from San Luis Reservoir to the Export Service Area until after San Luis reaches its lowpoint. EWA actions would cause pumping facilities in the Export Service Area, including Edmonston and Dos Amigos, to pump later in the year compared to the Baseline Condition. Electricity prices may be more expensive at the modified pumping times. This would cause potentially significant economic impacts. Mitigation measures listed in Section 16.3.9 would reduce these potentially significant effects on power production and energy to less than significant.

16.3.7 Environmental Consequences/Environmental Impacts of the Fixed Purchase Alternative

The Fixed Purchase Alternative would involve the same actions as the Flexible Purchase Alternative, although to a lesser degree. The Fixed Purchase Alternative limits Upstream from the Delta Region transfers to 35 TAF and Export Service Area transfers to 150 TAF. The Flexible Purchase Alternative scenarios allow transfers up to 600 TAF and do not specify transfer limits in the Upstream from the Delta Region or Export Service Area. The effects described for the Flexible Purchase Alternative represent the effects on water supply and management for a maximum transfer amount; therefore, impacts considered less than significant under this alternative also would be considered less than significant for a lesser transfer amount (the Fixed Purchase Alternative). Analysis of the Fixed Purchase Alternative incorporates implementation of the Variable Assets described in Attachment 1, Modeling Description. Pumping energy cost effects of the Fixed Purchase Alternative are discussed in Section 16.3.4.2.2.

16.3.8 Comparative Analysis of Alternatives

16.3.8.1 Upstream from the Delta Region

As described above, the Fixed Purchase Alternative would limit Upstream from the Delta Region transfers to a maximum acquisition of 35 TAF from all water sources. In most years, this amount could be obtained from stored reservoir water purchases. In subsequent dry years, this amount could be less than 35 TAF and the same for the Flexible Purchase Alternative due to the limited availability of water from the Upstream from the Delta reservoirs. The Flexible Purchase Alternative would permit Upstream from the Delta Region transfers of up to 600 TAF. The changes in timing of releases from reservoirs that generate power and on the costs for pumping of water from the Delta under the Flexible Purchase Alternative would be substantially different from that of the Fixed Purchase Alternative. Although the Fixed Purchase Alternative is not expected to significantly effect power, the Flexible Purchase Alternative may due to the volume of water involved in the transfers.

16.3.8.2 Export Service Area

The effects of the two alternatives in the Export Service Area relate to the effects to power generation and pumping for San Luis Reservoir. Management of EWA assets may release water earlier from San Luis at a time when power is less expensive and cause pumping of refill water at a time when power is more expensive. The Flexible Purchase Alternative will involve the release and pumping of more EWA assets than the Fixed Alternative and therefore would have greater effects on power. As described under the Export Service Area analysis for the Flexible Purchase Alternative, any potentially significant impacts can be mitigated by implementation of the Mitigation Measures presented in Section 16.3.9. These measures would also be applied to the Fixed Purchase Alternative.

Table 16-10 summarizes the potential effects upon power for both alternatives.

16.3.9 Mitigation Measures

During times when acquisition of water for EWA would result in the value of power generated later in the summer being less than under the Baseline Condition, the EWA Program is responsible for covering those additional costs, as outlined in the CALFED Record of Decision, under the EWA Operating Principles Agreement. The agreement states:

> "EWA shall impose no net, increased incremental costs upon the Projects. The Management Agencies and Project Agencies shall develop a financing plan to cover all costs of the EWA from non-contractor funding sources. The plan shall address increased Project operating costs, both power and ancillary costs, of both the SWP and CVP resulting from implementation of the EWA; crediting the EWA as appropriate for reduced operating costs; crediting the EWA for certain power benefits; and revenues realized from the sale of EWA assets . . . . Considering the importance of acquiring water to the success of the EWA, the Project Agencies and Management Agencies shall meet and confer to develop alternatives for funding power and other incidental costs, if such costs interfere with the successful operation of the EWA."

According to this agreement, EWA shall mitigate any adverse economic, reliability, capacity or operational effects to CVP/SWP power operations or Project power users as a result of implementing the EWA Program.

16.3.10 Potentially Significant Unavoidable Impacts

The Flexible Purchase Alternative does not have any potentially unavoidable impacts. The adverse effects on Project power reduction and increased pumping costs caused by the shifting in the timing of releases of water from Project reservoirs can be mitigated through implementation of the mitigation measures provided in Section 16.3.9.

16.3.11 Cumulative Effects

There is a potential for cumulative effects to CVP/SWP power production for other water acquisition programs that alter the timing of water releases from Project reservoirs. In the past, these programs have included specific terms for use of Project power in contractual documents. Recent year EWA water purchases have been facilitated by terms of Interim Protocol documents. Because the other programs remain in the planning stages, or are subject to CVP/SWP policies that are evolving, operational details of the programs cannot be described. Any power effects of these programs would not constitute environmental effects, but rather economic losses. The Flexible Purchase Alternative could purchase up to 600 TAF upstream from the Delta; these transfers would use all the export capacity of the CVP/SWP pumps. Therefore, the analysis of 600 TAF also covers the effects of other water purchases or transfers that convey water through the Delta. Power effects in the cumulative condition would be essentially the same as those shown for the Flexible Purchase Alternative.

Chapter 17
Cultural Resources

Native Americans initiated California's rich cultural heritage many generations before Europeans settled in the area. A third of all Native Americans within current U.S. boundaries lived in California. In the late 1600s, California's Hispanic forefathers began to build missions that attracted an influx of people from Europe, Africa, and many other countries. The 1849 Gold Rush initiated a significant migration of people from Africa, Chile, Mexico, China, France, England, Germany, Ireland, Australia, Hawaii, Philippines, and elsewhere (Starr 2000).

Preserving the culture and history of our nation's past are the goals of regulations that include the National Historic Preservation Act (NHPA), Antiquities Act of 1906, Archeological Resource Protection Act of 1979, and Historic Sites Act of 1935. The NHPA regulations (36CFR800) require that Federal agencies seek information, as appropriate, from the State Historic Preservation Officer (SHPO), the Advisory Council on Historic Preservation, Indian tribes, and other individuals and organizations likely to have knowledge of, or concerns with, historic properties in the area of potential effect. These organizations and individuals are integral in identifying issues related to the Program's potential effects on historic properties. Similar State regulations[1] protect archeological, paleontological, and historical sites and specifically provide for identification and protection of traditional Native American gathering and ceremonial sites on State land.

Cultural resources defined within the framework of these regulations include archeological sites, historic sites, and traditional cultural properties associated with the values of Native Americans and other cultural groups. While studying cultural resources provides insight into the adaptation of early people and reveals important information, actions that physically disturb a site, alter its setting, or introduce elements out of character with the site may constitute an adverse effect. If a site is eligible for inclusion in the National Register of Historic Places (NRHP), any type of physical damage results in a permanent loss of information that reduces our understanding of the site's contribution to the past.

17.1 Affected Environment/Existing Conditions

Environmental Water Account (EWA) actions could result in both beneficial and adverse effects on cultural resources. A description of the relationship between EWA actions and cultural resources follows:

- Acquisition of stored reservoir water, which could draw down reservoirs below the Baseline Condition in the Upstream from the Delta Region. These lower reservoir levels could increase exposure of cultural resources to increased cycles of

[1] Including but not limited to Public Resources Code (PRC) Sections 5097-5097.6, 5020.10, 5020.5, 5024.4(6), 5079.60, 5079.61, 5079.63, and Senate Resolution Number 87.

inundation and drawdown potentially eroding the value and character of the historical resource.

- Groundwater substitution and crop idling would increase reservoir levels from the Baseline Condition, as increasing amounts of water remain in the reservoir. Surface elevations in Folsom Lake and Lake Oroville would be higher than the Baseline Condition in April, May and June; elevations in Lake Shasta could increase in June under certain hydrologic conditions[2].

  Release of the water to EWA during July through September would decrease surface elevations to low operating levels earlier than the Baseline Condition. Releases would not exceed normal operating levels in Lake Shasta, Folsom Lake, and Lake Oroville reservoirs. Therefore, groundwater substitution and crop idling releases would not expose previously submerged artifacts and would not affect cultural resources in these reservoirs.

  The pattern of water releases from these reservoirs would change, which would change the flows in the rivers downstream. The rivers, however, would not decrease below minimum flows, and would stay within historic channels. Groundwater substitution acquisitions and the water transfer process involving crop idling would not affect cultural resources in Lake Shasta, Folsom Lake, and Lake Oroville reservoirs. Therefore, cultural resources in these reservoirs will not be discussed further.

- Crop idling would have the potential to affect cultural resources if fugitive dust from idled fields (Chapter 8, Air Quality) interfered with the character of nearby cultural resources. Air quality and soil erosion mitigation measures outlined in Section 8.2.7 would reduce potential air quality effects on cultural resources and this issue is not addressed further in this chapter.

- Source shifting would delay the delivery of water to participating State Water Project (SWP) or Central Valley Project (CVP) contractors, and the contractors would use an alternate source of supply. If these alternate supplies were drawn from a surface water reservoir, these reservoirs could draw down earlier in the year. The surface elevations would remain within historic levels. Pre-delivery of water to reservoirs proposed for source shifting would increase surface water elevations earlier in the year. Operational changes subsequent to source shifting would have no effect on cultural resources.

---

[2] Water from Lake Shasta is released in April and May to protect temperature and flow requirements on the Sacramento River. In some years, (depending on hydrologic conditions) Lake Shasta could store EWA water in June.

- The EWA actions will not make operational changes in the Delta that would affect cultural resources in the Delta region. Therefore the Delta is not an area of concern for cultural resources.

Section 7.11 of the Programmatic Environmental Impact Statement/Environmental Impact Report (CALFED PEIS/EIR) contains a general description of prehistoric resources, historic resources, traditional cultural properties, and Native American groups for each of the CALFED regions. The CALFED regions have different boundaries than the EWA regions, but they include the entire EWA study area (Chapter 3). The cultural resources information is incorporated by reference into this EIS/EIR; however, conclusions rely on information contained within this document.

The cultural resource descriptions in the CALFED PEIS/EIR do not include explanations of ethnographic resources because listings of properties with traditional cultural value are not always available through archeological, historical, or architectural surveys. For the purpose of this document ethnographic resources possess a dynamic, tangible relationship with traditional cultural properties. Traditional cultural properties are those eligible for inclusion in the National Register because of their association with cultural practices or beliefs of a living community that a) are rooted in that community's history, and b) are important in maintaining the continuing cultural identity of the community (Parker and King, 1998).

Because the CALFED PEIS/EIR provides general information on cultural resources, the following section focuses on tangible ethnographic resources in areas potentially affected by EWA water transfers and provides a general summary of historic resources in each river region. Identifying and maintaining traditional cultural properties and ethnographic resources is consistent with California guidance and U.S. Forest Service's California Native American policy.

This section describes existing cultural resources in regions affected by the EWA. The level of detail that is presented is proportional to the expected effect of EWA water transfers. The following description mainly focuses on areas potentially affected by acquisition of stored reservoir water and provides a less detailed analysis of areas proposed for source shifting.

17.1.1 Area of Analysis

Cultural resources analysis divides the study area into the Upstream from the Delta Region and the Export Service Area. Acquisitions that define the area of analysis include use of stored reservoir water and source shifting. In the Upstream from the Delta Region purchase of stored reservoir water could potentially affect cultural resources. Discussion will proceed from north to south along the Feather, Yuba, and American Rivers. There would be no acquisition of stored reservoir water from reservoirs on the Sacramento River. Reservoirs proposed for purchase of stored reservoir water along the Feather include Little Grass Valley and Sly Creek; New Bullards Bar on the Yuba; and French Meadows and Hell Hole reservoirs on the American River. The area of analysis includes a ¼ mile radius surrounding each reservoir.

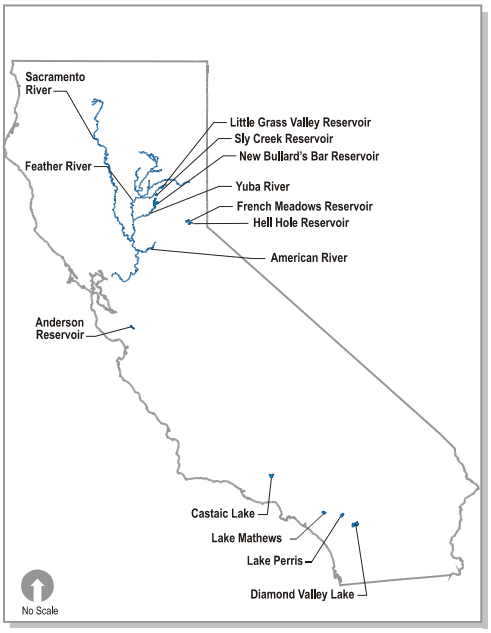

Figure 17-1
Cultural Resources Area of Analysis

Source shifting could potentially affect cultural resources in the Export Service Area. Reservoirs proposed for source shifting include Anderson Reservoir, Castaic Lake, Lake Perris, and Diamond Valley. (Please refer to Figure 17-1.)

17.1.2 Upstream from the Delta Region

Native American tribes that occupied the Upstream from the Delta Region at the time of contact included the Pit River Indians, Yana, Nisenan, Maidu, Konkow, and Sierra Miwok (Figure 17-2 and below). Evidence of the early human occupation along the headwaters of the Feather, Yuba, and American Rivers dates from 2000 B.C. or earlier to 500 A.D.

- Pit River Indians include the Achumawi and Atsugewi, whose traditional territory occupied areas within the northeastern part of California (Olmsted and Stewart 1978).

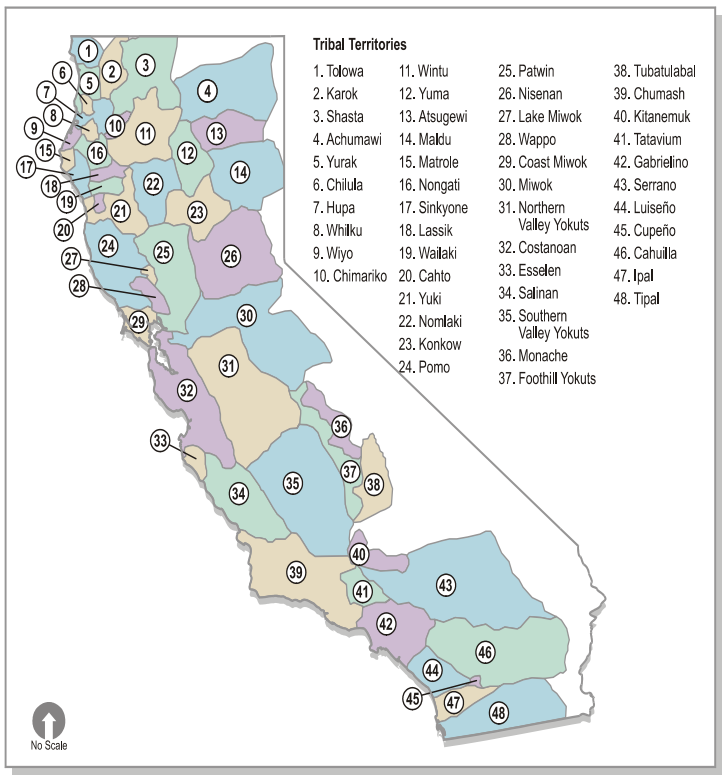

Figure 17-2
Linguistic Tribal Territories
(Native Web 2002)

- Yana traditionally occupied the northern portion of the Sierra Nevada. Yana territory extended from southwest of Mount Lassen to the upper reaches of the Sacramento River Valley (San Diego State University 2002).

- Valley Nisenan, sometimes referred to as Southern Maidu, had scattered villages along the margins of primary watercourses north of the Cosumnes River and were heavily dependent upon fish and acorns for subsistence. Hill and mountain Nisenan villages were on ridges adjacent to streams with a southern exposure or on terraces along rivers. Most Hill and mountain Nisenan villages had bedrock mortar grinding stations associated with them (Yuba County 1994). Maidu villages occupied knolls, terraces, and crests along drainages of the

Feather and American Rivers. The northeastern Maidu occupied the upper reaches of the North and Middle Forks of the Feather River (Kroeber 1925).

- The Konkow, also known as Northwestern Maidu, occupied territory below the high Sierra in the foothills where the south, middle, north, and west branches of the Feather River converge. Konkow territory included the upper Butte and Chico Creeks and part in the Sacramento Valley along the lower courses of the same streams (Kroeber 1925).

- Sierra Miwok territory extended over the Sierra Nevada foothills in the central part of California.

The climate and topography north of the Delta area supports a variety of forest, grassland, savannah, riparian, and wetland habitats. Native American groups that occupied the Yuba, American, and Feather River drainages survived on non-domesticated plants and animals that provided food and material for baskets, houses, and clothing. For generations, Native Californians created baskets from willows, sedge root, bulrush root and new shoots of the western redbud.

Some modern Native Americans maintain their culture by gathering vegetation and wildlife formerly used by their ancestors and performing traditional ceremonies. U.S. Forest Service policy encourages, protects, and perpetuates traditional tribal practices by reserving areas on Forest Service land for gathering basketry materials and practicing cultural traditions.

Historic properties include prehistoric and historic districts, sites, buildings, structures, or objects included in, or eligible for inclusion in, the NRHP [36CFR800.16(l)1)]. Historic age cultural resources in the upstream region include those associated with California's gold rush, such as mining machinery, sluices, cabins, and mills. Other historic sites include those pertaining to cattle ranches and wagon trains.

The following sections provide information on traditional cultural properties, historic properties and ethnographic resources in the Upstream from the Delta Region. This discussion is organized by river, and lists for each river area: early human and Native American groups that lived in the area; cultural surveys performed at locations of archeological interest; and number and nature of sites of cultural or historical importance.

17.1.2.1 Feather River

The Maidu occupied areas near the Feather River headwaters, and Nisenan lived in the downstream areas south of the Middle Fork of the Feather River. Traditional cultural practices of the Maidu and Nisenan include weaving baskets and tule mats. Maidu and Nisenan would coil peeled willow and peeled and unpeeled redbud in a clockwise manner to form baskets. Baskets were made to hold water by overlaying hazel shoots, pine roots, and maidenhair fern shoots and covering with pitch

(Schwartz 1958). Maidu also wove tule mats that they used for seats, beds, camp roofing, and doors (Kroeber 1925).

Historical landmarks are sites, buildings, features, or events of statewide significance that have anthropological, cultural, military, political, architectural, economic, scientific, or technical, religious, experimental, or other value (Office of Historic Preservation 2002). Upstream historic landmarks include gold mining sites of Dogtown, Nugget and Oregon City, along with the original propagation site of the Thompson seedless grape. Oroville Lake now covers Bidwell's Bar, the second county seat of Butte County. Another area of historical importance is an 1863 Chinese Temple commissioned by the Emperor and Empress of China. There are eight historical landmarks in Butte County (location of Sly Creek Reservoir) and thirteen in Plumas County (location of Little Grass Valley Reservoir).

Little Grass Valley and Sly Creek Reservoirs are upstream of Lake Oroville on the Feather River. Both reservoirs are in areas considered highly sensitive for prehistoric, protohistoric, and/or historic cultural resources (Ledwith, L. and Frank Bayham 2002).

17.1.2.1.1 Little Grass Valley Reservoir

Surveys for cultural resources exist for the northern half of Little Grass Valley Reservoir. Surveyed areas also include about half of the southern portion, private land along the southern edge, a small peninsula, and the southeastern side. Eleven Native American sites exist along the banks of the reservoir. The majority of the sites are prehistoric lithic scatters (flaked stone debris). The sites around Little Grass Valley Reservoir include two possible Martis Complex occupation sites and several bedrock milling stations. One site, described as a Martis Campsite, is inundated by the reservoir. The Martis Complex is a culture that precedes the advent of the bow and arrow (Yuba County 1994). Two additional sites have not yet been formally recorded, but they are a lithic scatter and a prehistoric basalt quarry.

One historic site and ten prehistoric sites have been recorded within the Little Grass Valley Reservoir boundaries. One site within the area of potential effect contains both historic and prehistoric remains. Two historic mining complexes with mining machinery and refuse are about ½ mile away from the reservoir and are outside of the area of potential effect. Eight studies by various individuals contain the breadth of information on this reservoir. (Carter 1978; Day 1982; Davis 1982; Lowdermilk 1989; Peterson 1993; Steidl 1993; Peterson 1994; Whittier 1999).

17.1.2.1.2 Sly Creek Reservoir

Much of the land around Sly Creek Reservoir is privately owned and not fully inventoried; however, three recorded prehistoric sites are known within the reservoir. One site is a campsite, and the other two are possible bedrock mortars where Native Americans processed acorns and other foods. One of the sites is now submerged in

Sly Creek Reservoir. (Manning 1981; Helm 1999;Murphy 1981; Day 1981; Manning 1981; and Lopez 1989).

17.1.2.2 Yuba River

Maidu and Nisenan occupied the Yuba River Region. These groups practiced the same ethnographic life ways as those stated above.

17.1.2.2.1 New Bullards Bar Reservoir

Investigation of the area around New Bullards Bar Reservoir, which is on the North Fork of the Yuba River, revealed prehistoric evidence of the Northwestern Maidu settlements and earlier distinct Mesilla and Martis cultural complexes. The east side of New Bullards Bar Reservoir, which experienced a recent fire, was subject to an intense pedestrian survey of cultural resources; inventories of the reservoir's west side are few. The reservoir contains 12 recorded prehistoric sites, two of which are also historic sites. Ten of the sites are inundated. Nine studies comprise the body of literature pertaining to the area within reservoir boundaries. (Riddell and Olsen 1966; Humphreys 1969; Anonymous 1979; Budy 1976; Meals 1978; Deal 1980; Stevens 1982; O'Halloran 1992; Baldrica 2000).

Seven California Historical Landmarks exist in Yuba County. Landmarks include the Bok Kai Temple that commemorates the original site of an 1850s Chinese temple and the temporary detention camp for Japanese-Americans in Marysville. Additional historic properties include the settlements of Smartsville and Johnson's Ranch (CERES 2002).

17.1.2.3 American River

The southern Maidu or Nisenan inhabited the upper and lower reaches of the American River watershed and practiced relatively the same cultural traditions and basketry production, as their northern tribal family. Prehistoric sites on the upper reaches of the American River include midden deposits (loose, dark soil with organic debris containing burned food, charcoal, bone, and rock), lithic scatters, petroglyphs, settlements with house pits, rock shelters, and bedrock mortars. These sites were large and small villages, cemeteries, resource procurement and processing, quarries, and ceremonial sites, workshops, and temporary campsites. Prehistoric archeological sites exist throughout the region, except on extremely rugged terrain and in areas without water. Most prehistoric sites of cultural interest in the area are found on gentle to moderately sloping sites within 500 feet of surface water sources (Placer County 1994).

Twenty California Historical Landmarks exist in Placer County, but few early gold rush buildings remain because miners and immigrants generally lived outdoors in cloth tents. Historic gold mining sites include an abandoned kiln in the middle of the Black Oak Golf Course and the Sisley mine industrial mill outside Penryn. Additional historic properties include Stanford Ranch north of Roseville and numerous small Depression-era concrete bridges built by laborers from the Work Projects Administration (Placer County 1994).

French Meadows and Hell Hole Reservoirs are along the Middle Fork of the American River. EWA agencies propose using these reservoirs for purchase of stored reservoir water.

17.1.2.3.1 Hell Hole Reservoir

The area within the Hell Hole Reservoir has not been surveyed extensively; four surveys cover the area within ½ mile of the reservoir. One prehistoric site is recorded to be within ½ mile of the reservoir. Three studies constitute the body of literature that applies directly to Hell Hole Reservoir (Peterson et al 1993; Lasick 1997; Goddard 1985).

17.1.2.3.2 French Meadows Reservoir

Surveys for cultural and historic resources exist for approximately 99 percent of French Meadows Reservoir and identify only a few sites within ½ mile of the project area. 1953 topographic maps reveal that there may be some unrecorded historic resources that are now under water. One archeological study identified a small "campsite" at the upper end of the reservoir (Shapiro and Jackson 1994). Six studies comprise the breadth of information written on French Meadows (Miller 1990; Smith 1978; Demasi 1981; Baldrica 1989; Smith 1994; Brooke 1999).

17.1.3 Delta Region

The Delta Region is one of the most intensely investigated areas of California because of its high prehistoric population density and proximity to population centers. Although the bulk of sites were recorded prior to 1960, there has been little systematic inventory for cultural resources. Most of the early archeological work in the region focuses on prominent prehistoric mounds. Documentation of historic sites has largely occurred within the last 20-30 years.

Native Americans in the Delta at the time of European contact were Northern Valley Yokuts who were settled along the San Joaquin River. Plains Miwok people lived primarily in the north with territory extending nearly to Sacramento (DWR, Reclamation 1996). Wintun and Nisenan occupied areas on the north and northeastern Delta. Those in the south Delta proper were the Chulamni or Nochochomne.

Many cultural resources exist within the Delta region, as described in Section 7.11 of the CALFED PEIS/EIR. Because EWA water acquisitions would not affect cultural resources in the Delta, no further description of cultural resources or historic properties is included here.

17.1.4 Export Service Area

The original inhabitants of the Export Service Area include the Yokuts and the Costanoans. The Costanoans claimed the coastal region from the southern border of San Francisco Bay south to Point Sur; descendants of the Costanoans currently refer to themselves as Ohlone.

The Ohlone lived in autonomous triblets each with a permanent village surrounded by a number of temporary camps. Poles, brush, and tule matting formed their dwellings. Tule also formed their rafts, the only boat known to Costanoans (Kroeber 1925, p. 468). Little is known of Costanoan basketry.

The Yokuts once occupied nearly all of the Tulare Basin, as well as portions of the Sierra Nevada foothills south of the Fresno River. The Yokuts had three main divisions – Northern Valley, Southern Valley, and Foothill. Each division comprised sixty triblets, and each triblet contained from a few hundred to several thousand individuals. Traditional land of the Northern Valley Yokuts spanned the junction of Bear Creek and San Joaquin River to the north, south nearly to Fresno, the Diablo Range to the west, and the western Sierra Nevada foothills to the east. Traditional land of the Southern Valley Yokuts spanned the Tulare, Buena Vista, and Kern lakes, their connecting sloughs, and lower portions of Kings, Kaweah, Tule, and Kern rivers (Merced County 2001).

The Yokuts efficiently incorporated tule into tribal life. Tule or bulrush, an emergent, grows most abundantly in muddy substrates found along the shores of shallow lakes, ponds, sloughs, and marshes. Tribal members incorporated tule into their permanent dwellings, which they often built in a street-like setting. Yokuts also used bundles of tule for their canoes.

Coiled jar-like vessels with flat shoulders and constricted necks are distinguishing characteristics of Yokuts' basketry. Red and black bands of either diamonds or hexagons mark the traditional Yokuts basket pattern (Kroeber 1925).

The following discussion describes cultural resources near reservoirs proposed for source shifting (Anderson Reservoir Lake Mathews, Castaic Lake, Lake Perris, and Diamond Valley).

17.1.4.1 Anderson Reservoir

Anderson Reservoir is located on a fault zone approximately two miles northeast of Morgan Hill in the Mt. Hamilton foothills. This reservoir operates in series with Coyote Reservoir to minimize pressure along the Calaveras fault. Anderson Reservoir was designed to handle a capacity of 89,073 acre-feet of water.

Artifacts reveal that a hunter/gatherer group called the Costanoans inhabited the region between 5000 and 7000 years ago. The Costanoans, currently known as the Ohlone, depended upon acorns, land animals, and marine resources for their subsistence.

During the Mexican Period (1821-1848) the fertile land was sold in 500-acre lots to Euro-American settlers. The reservoir currently covers one such 500-acre plot and resides within the Anderson Lake County Park. One of the features of the park is the Jackson Ranch Historic park site (Santa Clara Valley Water District 2001)

17.1.4.2 Castaic Lake

Castaic Lake is a 324,000 acre-foot reservoir. Reservoir levels generally peak in March and decrease until reaching a low in October. The design for Castaic Lake Reservoir accommodates surface elevation fluctuations of 90 feet (Young 2002).

Few early and middle period prehistoric archeological sites have been reported in the vicinity of Castaic Lake. (Horne 2002). Native American groups that inhabited the region include the Tataviam and the Gabrielino. The Tataviam heavily relied on yucca, and the Gabrielino exploited a wide range of marine resources. Gabrielino basketry is similar to that described for the Cahuilla (Kroeber 1925, p. 628)

Historic remnants of the gold and copper era, oil boom, Union Pacific Railroad, and archeological evidence of the Chinese labor camp era remain (Scientific Resource Surveys, Inc. 1988).

17.1.4.3 Lake Mathews

Lake Matthews is located just 60 miles from downtown Los Angeles in Riverside County. Lake Mathews is a 182,000 acre-foot reservoir that receives water from the Colorado River through Lake Havasu. Surface water elevations in Lake Mathews generally peak in May or June and reach their lowest during the late fall.

Lake Mathews is located near the westernmost extent of traditional Cahuilla territory. Other tribes occupying the region include the Serrano and Luiseno (Applied EarthWorks, Inc. 2002). An area about twenty miles east of Lake Mathews contains deeply stratified cultural deposits composed of a few flaked stone tools and abundant faunal remains (Applied EarthWorks, Inc. January 2002).

The Cahuilla baskets were rather heavy, regularly coiled bundles of grass stems. At times sumac splints or J*uncos* rush wrapped the baskets (Kroeber 1925, p. 698, 651). Luiseno basketry took on similar form.

17.1.4.4 Lake Perris

Lake Perris is a 131,000 acre-foot reservoir in Riverside County. Lake Perris occupies the historic home of the Indian tribes of Cahuilla, Serrano, and Luiseno (basketry described above). An archeological survey performed for Lake Perris found residential base camps and temporary camps "almost everywhere suitable milling surfaces are afforded by outcrops of granitic bedrock." The sites appear to have been temporary and able to produce little or no survivable residues (Scientific Resource Surveys, Inc. 1988).

A records search indicated 46 prehistoric archeological sites within 1 mile of the Lake Perris area. Of the 46 sites, six are classified as residential bases, four as temporary field camps, 31 as resource acquisition sites, and four as isolated cultural features. Excavations exposed circular rock hearths, earthen ovens, cobble scatters, bedrock

mortars, grinding slicks, and stone stools such as scrapers, perforators, and drills. (Scientific Resource Surveys, Inc. 1988).

Historically, Lake Perris was part of the Spanish Rancho called the San Jacinto Nuevoy Potrero. Prior to 1880, a few Mexican and Spanish miners worked the gold deposits in the surrounding hills. Following construction of the California Southern Railroad in 1881, settlers began staking out homesteads on railroad land. Although Perris Valley has a rich history, there are no properties within the Lake Perris area that are listed on the National Register of Historic Places, the California Historical Landmarks, the California inventory of Historic Resources, or at the Riverside County Parks Department Historical Section. A review of the 1898 USGS Elsinore Quadrangle indicates that 12 early 20th Century homesites were in existence at the time of mapping (Scientific Resource Surveys, Inc. 1988).

17.1.4.5 Diamond Valley Lake

When full, Diamond Valley Lake Reservoir is an 800,000 acre-foot reservoir that recently filled in December 2000 and became fully operational in January 2003. Construction of the Diamond Valley dam uncovered artifacts from the valley's human inhabitants, as well as fossils of prehistoric animals such as mammoth, mastodons, and giant long-horned bison. Several thousand fossils and the largest mastodon known in the west were unearthed (Metropolitan Water District 1991).

Archeological surveys for Diamond Valley Lake Reservoir identified 305 prehistoric archeological sites within the reservoir project area (Metropolitan Water District of Southern California 2001). Sites include: stone quarries, where prehistoric people procured quartz, quartzites, and metasiltstones for stone tool manufacture or flaked and ground stone; artifact scatters; and bedrock outcrops used for grinding and pounding plant foods.

Large prehistoric villages were found adjacent to major creeks and springs in Diamond valley. These villages contain circular rock rings, which are likely remnants of house structures, small rock enclosures, rock acorn granaries, bedrock grinding stations, fire hearths, and roasting platforms. Sites also contain a wide variety of flaked stone tools, such as dart points and arrow tips, bifacial knives, drills, scrapers, and choppers. Artifacts in the vicinity include bone awls, needles, clay pipes, pottery vessels, and abundant animal bones. Radiocarbon dating indicates that the people inhabited the area for the past 8,000 to 9,000 years, and the most intensive period of prehistoric occupation appears to have been within the past 500-700 years (McDougall June 2002).

17.2 Environmental Consequences/Environmental Impacts

17.2.1 Assessment Methods

The proposed action constitutes a Federal undertaking that requires compliance with Section 106 of the National Historic Preservation Act [16 USC 470(f)]; therefore, Federal significance criteria apply. For projects deemed undertakings, cultural

resource significance is evaluated in terms of eligibility for listing in the NRHP. NRHP criteria for eligibility are defined as follows:

> The quality of significance in American history, architecture, archeology, and culture is present in districts, sites, buildings, structures, and objects of State and local importance that possess integrity of location, design, setting, materials, workmanship, feeling and association, and that:
>
> (a) are associated with events that have made a contribution to the broad pattern of our history;
>
> (b) are associated with the lives of people significant in our past;
>
> (c) embody the distinct characteristics of a type, period, or method of construction, or that represent the work of a master, or that possess high artistic values, or that represent a significant and distinguishable entity whose components may lack individual distinction; or
>
> (d) have yielded, or are likely to yield, information important in prehistory or history (36 CFR 60.4).

Identifying and mitigating cultural resources eligible or listed on the National Register of Historic Places, California Register of Historical Resources, and/or unique archeological resources involves the following process:

1. Incorporate by reference the existing conditions defined within the CALFED PEIS/EIR. (The CALFED PEIS/EIR provides an adequate definition of cultural resources for performing a preliminary analysis on the areas potentially affected by EWA acquisition options.)

2. In consultation with State Historic Preservation Officer (SHPO) or the Tribal Historic Preservation Officer (THPO), determine the area of potential effect (APE) of EWA acquisitions. The APE is influenced by the scale and nature of the water transfer and would correspond to surface elevations that exceed the historic lower bounds of normal operational levels.

3. Review existing information on cultural resources within the area to identify whether historic properties are present within the APE.

4. Seek information from consulting parties, organizations, tribes, and individuals that have knowledge of the area's cultural resources and/or properties with religious and cultural significance. EWA agencies will exert a reasonable and good faith effort in identifying cultural resources within the APE.

5. In consultation with SHPO/THPO evaluate the eligibility of cultural resources, traditional cultural properties, and unique archeological resources by applying qualifications and guidance associated with the National Register of Historic Places, California Register of Historical Resources, and California Public Resources Code 21083.2(g).

6. In consultation with SHPO/THPO determine whether there are potential adverse effects that diminish the integrity of the historic properties location, setting, feeling, or association [36CFR800.5(a)(1)] or renders a substantial adverse change to the significance of a historic resource [CEQA 15064.5(b)].

7. When effects on historic properties cannot be fully determined prior to approval of the water transfer, development of a Programmatic Agreement (PA) is appropriate.

8. In consultation with SHPO/THPO develop a PA that implements measures to mitigate the project's effects on historic properties and unique archeological resources. Mitigation measures would be consistent with Federal and State law and regulation as appropriate, Reclamation's Directives and Standards (LND02-01), the Secretary of Interior's Standards, and 36 CFR 800. Mitigation measures would be developed in consultation with the SHPO/THPO, the Advisory Council on Historic Preservation, affected tribes, and interested parties.

Impact assessment focuses on historic properties, or sites designated as either historic resources or unique archeological resources.[3] Under State law, the evaluation of impacts on historic resources parallels Federal law. Properties protected under the California Environmental Quality Act (CEQA) include those eligible for listing or listed in the California Register of Historical Resources. The CEQA Guidelines state that if a project follows the Secretary of Interior's Standards for the Treatment of Historic Properties, the impacts are considered "mitigated to a level of less than a significant impact" (CEQA 15064.5[b][3]).

The EWA would include acquisition of water through the purchase of stored reservoir water from French Meadows, Hell Hole, New Bullards Bar, Little Grass Valley, and Sly Creek reservoirs. Stored reservoir water acquisition has the potential to affect cultural resources, if acquisitions result in changing operations beyond the normal range. Reservoir surface water elevation changes could expose previously inundated cultural resources to vandalism and/or increased wave action and erosion. These reservoirs are within three national forests: the Plumas, Eldorado, and Tahoe. Each forest is subdivided into several forest districts that retain their own cultural information. A records search performed by the Native American Heritage Commission did not identify any sites on the Sacred Lands Inventory List.

---

[3] As defined either in 36 Code of Federal Regulations (CFR) 800.16(l) for federal actions or in the State CEQA Public Resources Code (PRC) (21084.1 and 21083.2) and the CEQA Guidelines (15064.5[a])

The North Central Information Center (NCIC) and Northeast Central Information Centers (NEIC) are the State cultural resource information repositories for these reservoirs. The U.S.D.A. Forest Service maintains its own records. Each information center was provided USGS 7.5 minute topographic quadrangle maps delineating the reservoirs. The information centers provided existing prehistoric, historic, and archeological information from their archives. The Native American Heritage Commission noted that no locations of Native American cultural resources existed in the reservoir areas (Pilas-Treadway 2002).

Sources of NCIC information include the following:

- Office of Historic Preservation (OHP) Historic Property Directory;
- NCIC Resources Map;
- California Inventory (1976);
- California Department of Transportation Bridge Inventory (2000);
- California Historical Landmarks (1996);
- Points of Historical Interest (1992); and
- Historic Spots of California (1990).

NEIC literature included the information above and the following:

- National Register of Historic Places-Listed Properties and Determined Eligible Properties (1988, computer lists 1966 through 7-00 by National Park Service);
- California Register of Historic Resources (2002);
- Directory of Properties in the Historic Property Data File for Butte and Plumas Counties (2002);
- California Points of Historical Interest (1992);
- California Inventory of Historic Resources (1976);
- Historic Spots in California (1966); and
- Gold Districts of California (1970).

As the need arises, all available cultural information and reservoir surface elevation changes will be discussed with the SHPO to determine whether previous surveys adequately characterize cultural resources within the reservoirs, or whether data gaps exist. Since effects on cultural resources cannot be fully determined, a PA ((36 CFR 800.14(b)) will be completed to comply with NHPA Section 106. The PA may include land managing agencies, tribal entities, other interested parties as signatory, or concurring parties as appropriate.

The jurisdiction of applicable State and Federal laws that protect archeological and historical sites is contingent on several factors. Federal law applies to all Federal lands and to all projects sponsored, permitted, approved, or funded by Federal agencies. Private entities or State agencies receiving Federal funds for projects are required to comply with Federal law. State law applies to State agencies, city governments, or private entities implementing CALFED projects on private or State lands. The applicable laws are discussed in Chapter 1 of this document and in Section 7.11.4 of the CALFED PEIS/EIR.

17.2.2 Significance Criteria

Minor, moderate, or major effects on historic properties are potentially significant. Significant effects on important cultural resources require avoidance, mitigation measures, or consideration of alternative plans. The cultural resource effects assessment relies on the type of site, the type of effect, and the extent of the disturbance on historic properties (36 CFR 800.16(l)(1) or unique archeological resources (PRC Section 21083.2[g] and Section 21084.1). Direct effects are those that occur during program operations, such as reservoir surface elevation fluctuations that expose historic properties or increase the potential for their erosion.

Potentially significant adverse effects also can occur indirectly through the alteration of the character of the site setting and the introduction of visual, audible, or atmospheric elements that change the character of a site or its setting, which may affect the eligibility of the site for inclusion in the NRHP.

Significant impacts would be determined when operations:

- Expose previously submerged resources, increasing their vulnerability to vandalism and other factors; and
- Expose resources to increased cycles of inundation (erosion) and drawdown.

Studies of reservoir effects on cultural sites have shown that the greatest potential effects are from wave action, which erodes deposits and moves artifacts, and from cycles of inundation and drawdown, which also cause erosion and movement, in addition to repeated wetting and drying of the deposit (Foster, Bingham, Cart, Cooley-Reynolds, and Kelly 1977; Foster and Bingham 1978). The same authors suggest that sites that lie submerged permanently (e.g., within the deep pool of a reservoir), suffer much less damage than those within the drawdown zone. Sites at the present waterline (and that have not been subject to inundation before) would incur an adverse effect should water levels fluctuate.

17.2.3 Environmental Measures Incorporated into the Project Description

The following environmental measures are incorporated into the project description to reduce the EWA's potential effects on historic properties and unique archeological resources. Consistent with the NHPA, Reclamation will consult with SHPO and/or

THPO in identifying cultural resources in the area of potential effect and in identifying appropriate mitigation measures.

Acquisition of stored reservoir water from French Meadows, Hell Hole, New Bullards Bar, Little Grass Valley, and Sly Creek reservoirs that results in drawdown beyond baseline (historic) surface elevations exposing areas that have been unsurveyed for cultural resources would require further inventory and evaluation. Before completion of water acquisition contracts, consideration of cultural resources within the new drawdown zone would proceed as follows:

- Reclamation would forecast end of season reservoir levels to determine whether levels would exceed the normal historic operating range.
- If forecasts exceed historic operational water surface elevations, then Reclamation would request the transferring irrigation district or water agency to inventory and evaluate cultural resources within the added drawdown zone at end of season low points.
- Should the willing seller not agree to an inventory and evaluation of cultural resources, the transaction would proceed no further.

Historic lower bounds of surface elevations in each reservoir proposed for purchase of stored reservoir water are contained in Table 17-1. Provisions for exceeding these levels are contained within the Programmatic Agreement (36 CFR 800.14(b)) developed between Reclamation, SHPO, and other appropriate agencies.

Table 17-1
Historic Lower Bounds of Reservoir Surface Elevations

Reservoir	Historic end of month surface elevation feet mean sea level	Date Recorded
Little Grass Valley	3,462 feet	January 1985[(1)]
Sly Creek	3,355 feet	October 1976[(2)]
New Bullards Bar	1,711 feet	December 1980[(1)]
Hell Hole	4,416 feet	September 2001[(1)]
French Meadows	5,158 feet	October 1991[(1)]

Elevations do not reflect reservoir filling or levels associated with emptying for reservoir repair.
[(1)] CDEC 2002
[(2)] Petersen 2002

17.2.4 Environmental Consequences/Environmental Impacts of the No Action/No Project Alternative

The analysis of cultural resources during the Stage 1 phase of CALFED plan implementation shows that the current practices would remain constant over the assessment period. In the No Action/No Project Alternative, surface water facilities

would continue to operate in the same manner as current operations, which would continue to inundate and expose cultural resources located within regularly exposed drawdown zones. The U.S. Forest Service would continue to manage and protect cultural resources associated with reservoirs on Forest Service property. Extreme seasonal changes in riverflows (e.g., floods flow that preclude access; droughts that diminish stream bank vegetation) could interfere with Native American cultural practices on Forest Service property in the same frequency as today. Other than in these extreme conditions, the No Action/No Project Alternative would have no effect on cultural resources or Native American traditional practices.

Water and irrigation districts would continue to operate their systems as in the Affected Environment, where they frequently move water between facilities. Cultural resources would be subject to current effects, and the No Action/No Project Alternative would reflect the system it is presently operating.

The National Environmental Policy Act (NEPA) basis of comparison is the Future Conditions Without the Project. As described in the above paragraphs, the Affected Environment and the Future Conditions Without the Project are the same; therefore, they are collectively referred to as the Baseline Condition in the following sections.

17.2.5 Environmental Consequences/Environmental Impacts of the Flexible Purchase Alternative

The Flexible Purchase Alternative allows transfers up to 600,000 acre-feet and does not specify transfer limits in the Upstream from the Delta Region or the Export Service Area. Transfers in the Upstream from the Delta Region would range from 50,000 to 600,000 acre-feet. Hydrologic conditions and conveyance capacity through the Delta limit actual acquisitions. This section discusses the maximum transfer of stored reservoir water. Similarly, the evaluation includes an analysis of up to 540,000 acre-feet in the Export Service Area to cover the maximum transfer scenario for that region.

Negotiations for stored reservoir water with Placer County WA, Yuba County Water Agency (WA), and Oroville-Wyandotte Irrigation District (ID) are based on a number of factors, including price, water availability, and location. Based on need and hydrologic conditions, these factors change from year to year; therefore, EWA Project Agencies may choose to vary acquisition strategy annually. With the intent of providing the EWA Project Agencies the greatest flexibility when negotiating transfers with willing sellers, the following text describes the extent of impact potentially produced by maximum acquisition of stored reservoir water.

17.2.5.1 Upstream from the Delta

Upstream asset acquisitions that could affect cultural resources are limited to purchase of stored reservoir water from reservoirs along the Feather, Yuba, and American Rivers.

17.2.5.1.1 Feather River

EWA acquisition of Oroville-Wyandotte ID stored reservoir water would decrease surface water elevations October until refill for Sly Creek and Little Grass Valley Reservoirs. An initial 15,000 acre-foot transfer would likely draw between 10,000-12,000 acre-feet from Little Grass Valley Reservoir and between 3,000-5,000 acre-feet from Sly Creek Reservoir (Petersen 2002).

Little Grass Valley Reservoir

A 12,000 acre-foot withdrawal from Little Grass Valley Reservoir would result in a maximum decrease of 12 feet in surface elevation relative to baseline levels (represented by median monthly elevations over 40 years). Median surface elevations are the level at which 50% of the surface elevations are above and 50% are below that level. If hydrologic conditions result in elevations that fall below the median, the historically low surface elevation defines the lower bound limit of reservoir operations.

Oroville-Wyandotte ID maintains an average 48,000 acre-foot carryover storage in Little Grass Valley resulting in a baseline surface elevation of 5013 ft. Historic end of month surface elevations of Little Grass Valley range from 3,462 feet (January 1985) to 5,051 feet (May 1995) (California Data Exchange Center 2002). The decreased surface elevations could increase exposure of the 11 sites along the banks of Little Grass Valley Reservoir, yet would not bring attention to their locations nor subject them to additional wave action or erosion beyond naturally occurring reservoir fluctuations. Transfers that draw down surface elevations beyond historically low levels would result in a potentially significant effect. In such cases, Reclamation would require an inventory and evaluation of unsurveyed areas. Furthermore, Reclamation would consult with SHPO to identify appropriate mitigation measures that are found in Section 17.2.8, in accordance with the PA. Project proponents would coordinate cultural resource mitigation measures (Section 17.2.8) with Reclamation to reduce effects to less-than-significant levels.

Sly Creek Reservoir

A 5,000 acre-foot reduction of Sly Creek Reservoir would result in a maximum decrease of 17 feet of surface elevation relative to the Baseline Condition. Oroville-Wyandotte ID maintains an average 12,000 acre-foot carryover storage in Sly Creek results in a baseline surface elevation of 3,450 ft. Historic end of month surface elevations in Sly Creek range from 3,355 ft (October 1976) (Petersen 2002) to 3,539 feet (June 1978) (California Data Exchange Center 2002). The decreased surface levels could increase exposure of three sites in Sly Creek Reservoir, yet would not bring attention to their locations nor subject them to additional wave action or erosion beyond naturally occurring reservoir fluctuations. Transfers that draw down surface elevations beyond historically low levels would result in a potentially significant effect. In such cases, Reclamation would require inventory and evaluation of

unsurveyed areas. Furthermore, Reclamation would consult with SHPO to identify appropriate mitigation measures that are found in Section 17.2.8, in accordance with the PA. Project proponents and Reclamation would coordinate cultural resource mitigation measures to reduce effects to less-than-significant levels.

Surface elevations in these reservoirs are expected to refill in April, May, and June to within baseline parameters. The surface elevation fluctuations are potentially significant. Implementation of the mitigation measures described in Section 17.2.8 would reduce these effects to less-than-significant.

EWA acquisition of Oroville-Wyandotte ID stored reservoir water would increase Feather River flows upstream from Lake Oroville from October through December, prior to transfer downstream, and would increase Feather River flows downstream from Lake Oroville from July to September. Flow releases would remain within historic channels and would not change the availability of or accessibility to resources pertinent to Native American cultural practices on U.S. Forest Service lands surrounding the Oroville-Wyandotte ID reservoirs and downstream reaches of the rivers. There are no significant effects associated with changes in flow patterns on the Feather River.

Multi-year transfers of stored reservoir water are contingent on refill during winter months. If Little Grass Valley and Sly Creek reservoirs do not refill, then EWA agencies would not purchase water from Oroville-Wyandotte ID the following year. The same mitigation measures would apply to multi-year transfers to maintain effects to a less-than-significant level.

17.2.5.1.2 Yuba River

EWA acquisition of Yuba County Water Agency (WA) stored reservoir water would decrease surface water elevations from July until refill for New Bullards Bar Reservoir. Yuba County WA would agree to water transfers only after local needs, instream flow requirements, and system demands are met. Given proper hydrologic conditions, however, the EWA could acquire up to 100,000 acre-feet of water from reservoir storage in New Bullards Bar Reservoir dropping the surface elevation 24 feet below baseline (represented by median monthly elevations over a 40 year study period). Median values are the level at which 50% of the surface elevations are above and 50% are below that value. If hydrologic conditions result in elevations that fall below the median, the historically low surface elevation defines the lower bound limit of reservoir operations.

The reservoir's monthly surface elevations range from 1,711 ft (December 1980) to 1966 ft (June 1982) (California Data Exchange Center 2002. The operational target storage for the end of September is 1,873 ft (705,000 acre-feet), when hydrologic conditions allow. Stored reservoir water transfers could expose the ten inundated sites, yet would not bring attention to their previously submerged locations or subject them to additional wave action or erosion beyond naturally occurring reservoir fluctuations. Transfers that draw down surface elevations beyond historically low levels would result in a potentially significant effect. In such cases, Reclamation would require inventory and evaluation of unsurveyed areas. Furthermore,

Reclamation would consult with SHPO to identify appropriate mitigation measures that are found in Section 17.2.8, in accordance with the PA. Reclamation and project proponents would coordinate cultural resource mitigation measures (Section 17.2.8) to reduce effects to less-than-significant levels.

Multi-year transfers of stored reservoir water with Yuba County WA are dependent upon refill during winter months. The amount of water available for transfer the second year would be dependent upon the amount the reservoir refills (Onken 2003). Before initiating multi-year transfers, Yuba County WA would evaluate and analyze potential effects on cultural resources and apply the same mitigation measures that pertain to single year transfers to maintain effects at a less-than-significant level.

EWA acquisition of Yuba County WA stored reservoir water would increase flows on the Yuba River downstream from Englebright Dam from July to September. Release flows would remain within historic channels and flow ranges and would not affect availability of or accessibility to Native American cultural resources on U.S. Forest Service lands surrounding the New Bullards Bar Reservoir and the Yuba River downstream. There are no significant effects associated with changes in flow patterns on the Yuba River.

17.2.5.1.3 American River

EWA acquisition of Placer County WA stored reservoir water would decrease surface water elevations June to refill at Hell Hole and/or French Meadows reservoirs. The EWA agencies propose a 20,000 acre-foot acquisition of stored reservoir water in Hell Hole and French Meadows Reservoirs. Although the amount released from each reservoir would remain entirely at Placer County WA's discretion, this analysis assumes that 61 percent would be released from Hell Hole and the remainder from French Meadows. The acquisition would result in a 7,800 acre-foot reduction from French Meadows and a 12,200 acre-foot reduction from Hell Hole.

Hell Hole Reservoir

Surface elevations of Hell Hole range from 4,416 ft (September 2001) to 5,654 ft (May 1996) (California Data Exchange Center 2002). Hell Hole has an average 91,500 acre-foot carryover storage. A 12,200 acre-foot acquisition could result in a 14-foot reduction from median monthly surface elevations.

French Meadows

Surface elevations of French Meadows range from 5,158 ft (October 1991) to 5,261 (June 1982) (California Data Exchange Center 2002). French Meadows maintains an average 58,500 acre-foot carryover storage. A 7,800 acre-foot purchase of stored reservoir water from French Meadows would result in an 8-foot reduction in surface elevation.

Though both reservoirs are largely unsurveyed, decreased surface elevations could expose cultural resources, including the "campsite" at the top of French Meadows reservoir, yet would not bring attention to their locations nor subject them to additional wave action or erosion beyond naturally occurring reservoir fluctuations. Effects are less-than-significant. Transfers that draw down surface elevations beyond historically low levels would result in a potentially significant effect. In such cases, Reclamation would require inventory and evaluation of unsurveyed areas. Furthermore, Reclamation would consult with SHPO to identify appropriate mitigation measures that are found in Section 17.2.8, per the PA. Reclamation and project proponents would coordinate cultural resource mitigation measures found in Section 17.2.8 to reduce effects to less-than-significant levels.

Multi -year transfers of stored reservoir water from Placer County WA will proceed for as long as both Hell Hole and French Meadows Reservoirs do not drop below a combined 50,000 acre-feet of storage. Before initiating multi-year transfers, Placer County WA would evaluate and analyze potential effects on cultural resources and apply the same mitigation measures that pertain to single year transfers to maintain effects at a less-than-significant level.

EWA agencies acquisition of Placer County WA stored reservoir water would increase American River flows downstream from Ralston Afterbay to Folsom Lake from June to October. American River flows would decrease downstream from French Meadows to Folsom Lake during refill of Hell Hole and French Meadows reservoirs. Release flows would remain within historic channels and flow ranges. American River flows during reservoir refill are protected by instream flow requirements and power production requirements. There are no significant effects associated with changes in flow patterns on the American River.

17.2.5.2 Export Service Area

Source shifting and pre-delivery are the only operational tools that could involve cultural resources in the Export Service Area.

17.2.5.2.1 Export Service Area Reservoirs

Anderson Reservoir

A Santa Clara Valley Water District 20,000 AF source shift would change the pattern of surface water elevation changes at Anderson Reservoir. Source shifting would delay deliveries of SWP water to Santa Clara Valley Water District, which would alternatively cause Santa Clara Valley Water District (SCVWD) to deliver water from the Anderson Reservoir. Surface elevations would decline earlier than the Baseline Condition and more frequently approach the lower levels of normal operational parameters. Fluctuations in reservoir elevations range between 558 ft (20 TAF) and 625 ft (89 TAF), which correspond respectively with the minimum emergency reserve and reservoir capacity. Because the water levels would be within historic levels, source shifting would not expose any additional cultural resources. Cultural resources

would remain intact relative to the Baseline Condition; therefore, there would be no effects posed by EWA source shifting.

Castaic Lake

A Metropolitan Water District (WD) source shift would change the pattern of surface water elevation changes at Castaic Lake. Source shifting would delay deliveries of SWP water to Metropolitan WD, which could cause Metropolitan WD to use water from Castaic Lake. Although Metropolitan WD could exercise flexible storage rights in Castaic Lake to serve as an alternate water supply, Metropolitan WD has many other alternate supply sources, e.g., Lake Mathews, Hayfield Groundwater Storage, or it may reduce deliveries to Arvin-Edison Water Storage District (WSD) or Semitropic WSD. Alternatively, Metropolitan WD could change water blending strategies.

Use of Castaic Lake as an alternate supply source could cause surface water levels to decline earlier in the year than they would in the Baseline Condition and more frequently approach the lower levels of normal operational parameters. The changes in the pattern of surface elevations would remain within historic levels. Fluctuations of the reservoir range between their lowest in August 1984 (1,398 ft) and their highest in February 1986 (1,515 ft) (California Data Exchange Center 2002). Because the water levels would be within historic levels, source shifting would not expose any additional cultural resources. Cultural resources would remain intact relative to the Baseline Condition; therefore, there would be no effects posed by EWA source shifting.

Lake Perris

A Metropolitan WD source shift would change the pattern of surface water elevation changes at Lake Perris. Source shifting would delay deliveries of SWP water to Metropolitan WD, which could cause Metropolitan WD to use water from Lake Perris. Although Metropolitan WD could exercise flexible storage rights in Lake Perris that could serve as an alternate water supply, Metropolitan WD has multiple alternate supply sources (see above). Use of Lake Perris as an alternate supply source could cause surface water levels to decline earlier in the year than they would in the Baseline Condition, and surface elevations would more frequently approach the lower levels of normal operational parameters. The changes in the reservoir levels would remain within historic levels. Surface elevations in Lake Perris historically range from 1,564 ft msl (October 1977) to 1,588 ft msl (July 1999) (California Data Exchange Center 2002). Because the water levels would be within historic levels, source shifting would not expose any additional cultural resources. Cultural resources would remain intact relative to the Baseline Condition; therefore, there would be no effects posed by EWA source shifting.

Diamond Valley Lake

Source shifting from Metropolitan WD would decrease surface water elevations at Diamond Valley Lake. Source shifting would delay deliveries of SWP water to Metropolitan WD. Diamond Valley Lake is one of many alternate water supply sources available to Metropolitan WD. If Metropolitan WD elects to use this reservoir, surface elevations would decrease earlier in the year than they would in the Baseline Condition, and surface elevations would more frequently approach the lower levels of projected normal operational parameters. Because this 800,000 acre-foot reservoir recently filled in December 2002 and was fully operational by January 2003, normal operational parameters have yet to be established. Average surface elevations in Diamond Valley Lake are projected to fluctuate approximately 42 feet, with an additional 30 feet in dry years. During the second year of a drought, reservoir surface elevations would be approximately 100 feet below maximum elevation. While filling, the cultural resources within the reservoir footprint experienced periods of exposure, inundation, drawdown, and erosion that were identified and mitigated in the environmental document pertaining to this reservoir. EWA source shifting effects are less-than-significant.

17.2.6 Environmental Consequences/Environmental Impacts of the Fixed Purchase Alternative

The Fixed Purchase Alternative specifies purchases of 35,000 acre-feet in the Upstream from the Delta Region and 150,000 acre-feet from the Export Service Area. Cultural effects that would be less-than-significant for the Flexible Purchase Alternative would also be less-than-significant for the Fixed Purchase Alternative. These effects include:

- Increased surface elevations on non-Project reservoirs on the Feather, Yuba, and American Rivers.
- Increased flows on the Feather, Yuba, and American Rivers during release of stored reservoir water;
- Decreased flows on the Feather, Yuba, Rubicon, and Middle Fork of the American Rivers during refill of reservoirs;
- Decreasing reservoir elevations in Export Service Area reservoirs earlier in the season when compared to the Baseline Condition.

If transfers result in exceeding historically low elevations, then Reclamation would consult with SHPO and/or THPO and identify appropriate mitigation measures that would reduce effects to a less-than-significant level.

17.2.6.1 Upstream from the Delta Region

17.2.6.1.1 Feather River

EWA acquisition of Oroville-Wyandotte ID stored reservoir water would decrease surface water elevations October until refill for Sly Creek and Little Grass Valley reservoirs. An

initial 15,000 acre-foot transfer would likely draw between 10,000 and 12,000 acre-feet from Little Grass Valley Reservoir and between 3,000 and5,000 acre-feet from Sly Creek Reservoir (Petersen 2002). These amounts are the same as those described for the Flexible Purchase Alternative. Similar to the Flexible Purchase Alternative, the decreased surface levels could expose cultural resources, yet would not bring attention to their previously submerged locations nor submit them to increased weathering beyond historic reservoir fluctuations. Transfers that draw down surface elevations beyond historically low levels would result in a potentially significant effect. In such cases, Reclamation would require inventory and evaluation of unsurveyed areas. Furthermore, Reclamation would consult with SHPO to identify other appropriate mitigation measures. Reclamation and project proponents will discuss protective mitigation measures described in Section 17.2.8, per the PA, to maintain less-than-significant effects on cultural resources.

EWA acquisition of Oroville-Wyandotte ID stored reservoir water would increase Feather River flows upstream from Lake Oroville from October through December, prior to transfer downstream, and would increase Feather River flows downstream from Lake Oroville from July to September. The amount of water that would be transferred under the Flexible Purchase Alternative could be transferred under the Fixed Purchase Alternative. As stated above, there are no significant effects from decreased flows on the Feather River.

Multi-year transfers involving stored reservoir water with Oroville-Wyandotte Irrigation District are contingent on refill during winter months. If Little Grass Valley and Sly Creek reservoirs do not refill, then EWA agencies would not purchase water the following year. The same mitigation measures would apply to multi-year transfers to maintain effects at a less-than-significant level.

17.2.6.1.2 Yuba River

EWA acquisition of Yuba County Water Agency (WA) stored reservoir water would decrease surface water elevations from July until refill for New Bullards Bar Reservoir. EWA agencies could acquire a maximum 35,000 acre-foot transfer from New Bullards Bar Reservoir, dropping the surface elevation 8 feet below baseline. The reservoir's average monthly surface elevations range from 1758 ft (January 1981) and 1966 ft (June 1982) (California Data Exchange Center 2002). Decreased surface elevations could expose inundated sites, yet would not bring attention to their previously submerged site nor subject them to increased weathering beyond historic reservoir fluctuations. Transfers that draw down surface elevations beyond historically low levels would result in a potentially significant effect. In such cases, Reclamation would require inventory and evaluation of unsurveyed areas. Furthermore, Reclamation would consult with SHPO to identify appropriate mitigation measures that are found in Section 17.2.8, in accordance with the PA. Reclamation and project proponents would coordinate the implementation of mitigation measures to reduce effects to a less-than-significant level.

EWA acquisition of Yuba County WA stored reservoir water would increase flows on the Yuba River downstream from Englebright Dam from July to September. The amount of water that would be transferred under the Flexible Purchase Alternative could be transferred under the Fixed Purchase Alternative. As stated above, there are no significant effects from decreased flows on the Yuba River.

Multi-year transfers of stored reservoir water with Yuba County WA are dependent upon refill during winter months. The amount of water available for transfer the second year would be dependent upon the amount the reservoir refills (Onken 2003). Before initiating multi-year transfers, Yuba County WA would evaluate and analyze potential effects on cultural resources and apply the same mitigation measures that pertain to single year transfers to maintain effects at a less-than-significant level.

17.2.6.1.3 American River

EWA acquisition of Placer County WA stored reservoir water would decrease surface water elevations June to refill at Hell Hole and/or French Meadows Reservoirs. The EWA agencies propose a maximum 20,000 acre-foot acquisition of excess stored reservoir water from Hell Hole and French Meadows Reservoirs. This amount is the same as described for the Flexible Purchase Alternative. Similar to the Flexible Purchase Alternative, decreased surface water elevations could expose cultural resources, yet would not bring attention to their previously submerged site nor subject them to increased weathering beyond historic reservoir fluctuations. Transfers that draw down surface elevations beyond historically low levels would result in a potentially significant effect. In such cases, Reclamation would require inventory and evaluation of unsurveyed areas. Furthermore, Reclamation would consult with SHPO to identify appropriate mitigation measures that are found in Section 17.2.8, in accordance with the PA. Project proponents and Reclamation would coordinate implementation and coordination of mitigation measures that would reduce effects to less-than-significant.

EWA agencies acquisition of Placer County WA stored reservoir water would increase American River flows downstream from Ralston Afterbay to Folsom Lake from June to October. American River flows would decrease downstream from French Meadows to Folsom Lake during refill of Hell Hole and French Meadows reservoirs. The amount of water that would be transferred under the Flexible Purchase Alternative could be transferred under the Fixed Purchase Alternative. As stated above, there are no significant effects from decreased flows on the American River.

Multi-year transfers of stored reservoir water from Placer County WA will proceed for as long as both Hell Hole and French Meadows reservoirs do not drop below a combined 50,000 acre-feet of storage. Before initiating multi-year transfers, Placer County WA would evaluate and analyze potential effects on cultural resources and apply the same mitigation measures that pertain to single year transfers to maintain effects at a less-than-significant level.

17.2.6.2 Export Service Area

A Metropolitan Water District (WD) source shift would change the pattern of surface water elevation changes at Castaic Lake, Diamond Valley Lake, and Lake Perris. The amount of

water that would be transferred under the Flexible Purchase Alternative could be transferred under the Fixed Purchase Alternative. Metropolitan WD could elect to use all the reservoirs for source shifting. Surface elevations in all reservoirs would decrease earlier in the season than in the Baseline Condition and more frequently approach the lower levels of normal operational parameters; however, elevations would remain within historic parameters. Cultural resources would remain intact relative to the Baseline Condition; therefore, there would be no effects posed by EWA source shifting.

17.2.6.2.1 Anderson Reservoir

A maximum 20,000 acre-foot Santa Clara Valley Water District source shift would change the pattern of surface water elevation changes at Anderson Reservoir. Source shifting would delay deliveries of SWP water to Santa Clara Valley Water District, which would alternatively cause SCVWD to deliver water from the Anderson Reservoir. Surface elevations would decline earlier than the Baseline Condition and more frequently approach the lower levels of operational parameters; however, surface elevations would remain within historic limits. Fluctuations in reservoir elevations range between 558 ft (20 TAF) and 626 ft (89 TAF), which correspond respectively to the minimum emergency reserve and reservoir capacity. Because the water levels would be within historic levels, source shifting would not expose any additional cultural resources. Cultural resources would remain intact relative to the Baseline Condition; therefore, there would be no effects posed by EWA source shifting.

17.2.7 Comparative Analysis of Alternatives

This section provides comparative effects analysis that would result from maximum stored reservoir water acquisitions. This addresses all possible effects, or a "worst-case scenario", that would occur should all acquisitions happened in the same year. The approach provides the EWA Project Agencies the flexibility to choose transfers that may be preferable in a given year. EWA agencies, however, would not actually purchase all of this water in the same year. This section provides information about how EWA agencies would more likely operate in different year types.

During No Project conditions, cultural resources within the program reservoirs experience exposure, inundation, and erosion that correspond to surface elevation fluctuations. During dry periods and extreme drought, cultural resources may become exposed, but locations remain unknown and protected. Wet hydrologic conditions inundate cultural resources and protect them from exposure. Surface elevation variations between the two hydrologic extremes result in wave action that could cause natural erosion in the Baseline Condition. Surface elevation changes associated with hydrologic cycles are unpredictable and difficult to differentiate between the effects caused by natural fluctuations and reservoir operations that occur in the Baseline Condition.

In the Upstream from the Delta Region, the Fixed Purchase Alternative would be limited to a maximum 35,000 acre-foot acquisition from all sources of water. This

amount could typically be obtained from stored reservoir water purchases in most year types. During wet years New Bullards Bar could facilitate the entire 35,000 acre-foot acquisition of stored reservoir water, yet distributing the purchase between the other candidate reservoirs would reduce potential exposure of cultural resources in all reservoirs. In very dry years, stored reservoir water may not be available, and the EWA agencies would need to look to other sources such as crop idling.

The Flexible Purchase Alternative could involve a maximum 600,000 acre-foot purchase from all sources in the Upstream from the Delta Region. EWA agencies would prefer to purchase reservoir water because the water is generally less expensive. The amount that could be purchased would be limited by the available capacity of the Delta export pumps to move the water to export areas south of the Delta. During wet years, excess pump capacity may be limited to as little as 60,000 acre-feet of EWA asset water because the pumps primarily would be used to export State and Federal Project water to Export Service Area users. Wet year acquisitions would need to rely more on crop idling in the Export Service Area, which would decrease the risk of affecting cultural resources in the non-Project reservoirs.

During dry years when there would be greater Delta pump capacity, the EWA Project Agencies could acquire up to 600,000 acre-feet of water from all sources in the Upstream from the Delta Region. Extending the drawdown zone beyond the historic Baseline Condition during dry years is dependent upon the availability of the less expensive water; however, it is likely that EWA Project Agencies would depend more upon stored reservoir water during dry years. Mitigation measures that would reduce potential effects to a less- than-significant level are discussed in Section 17.2.8 and would be implemented if transfers would exceed historic lower bound reservoir levels. Table 17-2 compares the Flexible and Fixed Purchase Alternatives to the Baseline Condition.

Table 17-2
Comparison of Impacts on Cultural Resources for Flexible and Fixed Purchase Alternatives

Region	*Sub-region*	*Asset Acquisition or Management*	*Result*	*Impacts*	*Flexible Alternative Change*	*Fixed Alternative Change*	*Significance of Flexible Alternative*	*Significance of Fixed Alternative*
Upstream from the Delta	Feather River	Stored Reservoir Water	Water released from Sly Creek and Little Grass Valley Reservoirs	Sly Creek and Grass Valley Reservoir levels decrease December until refill	Surface elevations in Sly Creek reduced by 17 feet and in Grass Valley surface by 12 feet	Surface elevations in Sly Creek reduced by 17 feet and in Grass Valley surface by 12 feet	Reservoir drawdown below historic elevations would be potentially significant. Appropriate mitigation measures produced through consultation would reduce effects to a less - than- significant level.	Reservoir drawdown below historic elevations would be potentially significant. Appropriate mitigation measures produced through consultation would reduce effects to a less - than- significant level.

Table 17-2
Comparison of Impacts on Cultural Resources for Flexible and Fixed Purchase Alternatives

Region	Sub-region	Asset Acquisition or Management	Result	Impacts	Flexible Alternative Change	Fixed Alternative Change	Significance of Flexible Alternative	Significance of Fixed Alternative
				Seasonal flow changes increase upstream from Oroville October through December	Flows increase upstream from Oroville October through December, yet remain within historic channels	Flows increase upstream from Oroville October through December, yet remain within historic channels	No significant effect	No significant effect
				Seasonal flow changes increase downstream from Oroville July to September	Flows increase downstream from Oroville October through December, yet remain within historic channels	Flows increase downstream of Oroville October through December, yet remain within historic channels		
			Sly Creek and Little Grass Valley reservoirs refill	Seasonal flow changes decrease upstream and downstream of Oroville during refill of Sly Creek and Little Grass Valley	Feather River flows decrease during refill, and are protected by instream flow and power production requirements	Feather River flows decrease during refill, and are protected by instream flow and power production requirements		
	Yuba River	Stored Reservoir Water	Water is released from New Bullards Bar	New Bullards Bar Reservoir levels decrease	Surface elevations in New Bullards Bar decrease up to 24 ft	Surface elevations in New Bullards Bar decrease up to 8 ft	Reservoir drawdown below historic elevations would be potentially significant. Appropriate mitigation measures produced through consultation would reduce effects to a less - than- significant level.	Reservoir drawdown below historic elevations would be potentially significant. Appropriate mitigation measures produced through consultation would reduce effects to a less - than- significant level.
			Water is released from New Bullards Bar	Yuba River flows increase	Yuba River flows increase during release, yet remain within historic river channels	Yuba River flows increase during release, yet remain within historic river channels	No significant effect	No significant effect
			New Bullards Bar refills	Yuba River flows decrease	Yuba River flows decrease during refill, but flows are protected by instream flow and power production requirements	Yuba River flows decrease during refill, but flows are protected by instream flow and power production requirements	No significant effect	No significant effect

Table 17-2
Comparison of Impacts on Cultural Resources for Flexible and Fixed Purchase Alternatives

Region	*Sub-region*	*Asset Acquisition or Management*	*Result*	*Impacts*	*Flexible Alternative Change*	*Fixed Alternative Change*	*Significance of Flexible Alternative*	*Significance of Fixed Alternative*
	American River	Stored Reservoir Water	Water is released from French Meadows and Hell Hole Reservoirs	French Meadows and Hell Hole Reservoir surface elevations decrease June until refill	Surface elevations decrease in French Meadows by 8 ft and in Hell Hole by 14 ft	Surface elevations decrease in French Meadows by 8 ft and in Hell Hole by 14 ft	Reservoir drawdown below historic elevations would be potentially significant. Appropriate mitigation measures produced through consultation would reduce effects to a less - than- significant level.	Reservoir drawdown below historic elevations would be potentially significant. Appropriate mitigation measures produced through consultation would reduce effects to a less - than- significant level.
			Water is released from French Meadows and Hell Hole Reservoirs	American River flows increase	Flows on American River increase June until October, yet flows remain within historic channels	Flows on American River increase June until October, yet flows remain within historic channels	No significant effect	No significant effect
			French Meadows and Hell Hole Reservoirs refill	Flows on the American River between French Meadows/Hell Hole Reservoirs and Folsom Lake are decreased during refill	Rubicon River flows decrease during refill of Hell Hole and flows on Middle Fork of American decrease during refill of French Meadows. Flows are protected by instream flow and power production requirements.	Rubicon River flows decrease during refill of Hell Hole and flows on Middle Fork of American River decrease during refill of French Meadows. Flows are protected by instream flow and power production requirements .	No significant effect	No significant effect
Export Service Area	Source Shifting	Source shifting in MWD reservoirs	Water is drawn from MWD reservoirs and from storage in SWP's Castaic Lake and Lake Perris	Transfers could change the pattern of surface water elevations	Maximum 200 TAF transfer could decrease surface elevations earlier in the year and more frequently approach the lower levels of normal operations	Maximum 200 TAF transfer could decrease surface elevations earlier in the year and more frequently approach the lower levels of normal operations	Less- than - significant effect	Less- than - significant effect
	Source Shifting	Source shifting in SCVWD reservoirs	Water is drawn from storage in Anderson Reservoir	Transfers could change the pattern of surface water elevations	Maximum 20,000 acre-foot transfer could decrease surface elevations earlier in the year and more frequently approach the lower levels of normal operations	Maximum 20,000 acre-foot transfer could decrease surface elevations earlier in the year and more frequently approach the lower levels of normal operations	Less- than - significant effect	Less- than - significant effect

17.2.8 Mitigation Measures

Stored reservoir water transfers from French Meadows, Hell Hole, New Bullards Bar, Little Grass Valley, and Sly Creek reservoirs could result in drawdown beyond historic operating levels and expose previously unsurveyed cultural resources. Stored reservoir water transfers that exceed the lower bounds of historic levels will require inventory and evaluation of unsurveyed areas. Consultation with SHPO would result in identifying appropriate mitigation measures that would reduce effects on cultural resources to a less-than-significant level.

Reclamation will forecast end of season reservoir levels to determine whether transfers would exceed normal historic operational levels and, where appropriate, transferring agencies would conduct inventory and evaluations of cultural resources in areas of potential effects. Appropriate mitigation measures would be identified in consultation with SHPO through the following process.

- If irrigation and water agencies proceed with cultural resource inventory and evaluation and find potential historic properties, a determination of effect document would be prepared.

- The results of the inventory, evaluation, and determination of effect would require Reclamation to consult through the PA with the SHPO, the U.S. Forest Service, other appropriate Federal and non-Federal agencies, and landowners (36 CFR 805.6) on the potential for adverse effects and to determine appropriate mitigation measures to historic properties. Mitigation measures included in the PA will comply with Section 106 of the National Historic Preservation Act.

- Historic property mitigation could involve research of historical records, previous cultural resources reports and data, and the detailed recording and/or excavation for data recovery. Additional measures may include protection or avoidance.

Impacts to resources covered under U.S. Forest Service's California Native American policy will require the EWA agencies to notify potentially affected Native Americans and to issue follow-up letters identifying potential impacts and appropriate mitigation measures.

17.2.9 Potentially Significant and Unavoidable Impacts

There are no expected significant and unavoidable effects on cultural resources. Mitigation measures (Section 17.2.8) would reduce potential effects to a less-than-significant level.

17.2.10 Cumulative Effects

Cumulative effects analysis for cultural resources focuses on those programs that potentially acquire water through stored reservoir water purchase and crop idling.

Other water acquisition programs include the Sacramento Valley Water Management Agreement, Dry Year Purchase Program, Drought Risk Reduction Investment Program (DRRIP), Central Valley Project Improvement Act Water Acquisition Program (WAP), and the Environmental Water Program. Although all programs include the option to purchase stored reservoir water during dry years, only the WAP and the Environmental Water Program would acquire reservoir water during wet years from upstream from the Delta reservoirs. The Environmental Water Program and the EWA would, however, purchase water from different facilities. Other future acquisition programs may also develop that adopt transactions involving stored reservoir water. All transfers that lower reservoirs could incrementally increase the drawdown zone to beyond the historic Baseline Condition. Cumulatively, this is a potentially significant effect. EWA agencies would mitigate EWA-produced effects to less-than-significant levels.

Mitigation would require cultural resource inventory and evaluation of property within the added drawdown zone and development of appropriate cultural resource protection. Cultural resource inventory and evaluation serve to adequately recover the scientifically consequential information from and about cultural resources, especially in terms of archeological resources. The intent of identifying potential archeological resources and historic properties is to identify appropriate mitigation measures that would avoid potential damage or destruction and reduce possible impacts to a less-than-significant level.

A cumulative effect would only be considered significant if the combined actions of all programs exceeded historic operational levels. In such conditions, the EWA would not contribute to a cumulative effect, as EWA agencies would not purchase water from an agency if the purchase would cause a cumulatively significant impact on cultural resources.

Chapter 18
Visual Resources

Both natural and artificial landscape features contribute to perceived visual images and the aesthetic value of a view. The value is determined by contrasts, forms and textures exhibited by geology, hydrology, vegetation, wildlife, and man-made features. Individuals respond differently to changes in the physical environment, depending on prior experiences and expectations and proximity and duration of views. Therefore, visual effects analyses tend to be highly subjective in nature. The following sections describe the existing visual resource conditions of the areas that could be affected by water acquisitions and an analysis of potential effects.

18.1 Affected Environment/Existing Conditions

18.1.1 Area of Analysis

Effects are assessed in the Upstream from the Delta Region, Delta Region, and in the Export Service Area. This discussion focuses on the areas where EWA actions would take place (Figure 18-1):

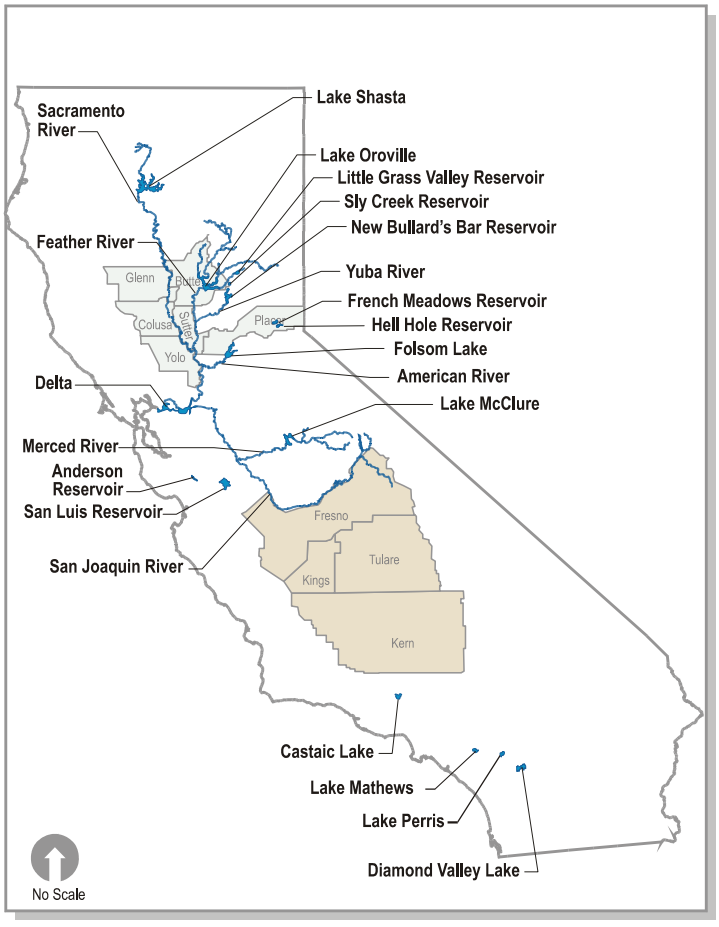

Figure 18-1
Visual Resources Area of Analysis

- Upstream from the Delta Region: Lake Shasta; Little Grass Valley and Sly Creek Reservoirs; Lake Oroville; New Bullards Bar Reservoir; French Meadows and Hell Hole Reservoirs; Folsom Lake; Lake McClure; Sacramento, Feather, Yuba, American, and Merced Rivers; crop idling areas in Glenn, Colusa, Yolo, Sutter, Butte, and Placer Counties.
- Delta Region
- Export Service Area: Anderson Reservoir; San Luis Reservoir and O'Neill Forebay; Lake Perris; Castaic Lake; Diamond Valley Lake; and Lake Mathews.

18.1.2 Upstream from the Delta Region

The Upstream from the Delta Region is bordered on the east by the Sierra Nevada, on the northwest by the Coast Ranges, and on the south by the northern extent of the San Joaquin River watershed. Agriculture in the Central Valley, forests in the upper watersheds, and grasslands and woodlands in the foothills characterize the region visually. Other low-elevation characteristics include occasional wetlands, vernal pools, and riparian areas. Much of the upper watershed on the east side of the Central Valley is forested, which limits views for motorists traveling through the area. Scenic stream corridors in the foothills include the Feather, Bear, Yuba, American, and Merced Rivers, and their smaller tributaries.

Historical changes from grasslands, floodplains, and extensive riparian areas to cropland, rice fields, and orchards have altered the visual variety in the Central Valley portion of the Upstream from the Delta Region. The valley floor is primarily irrigated agriculture that is Variety Class C – the least visually distinctive category (see Section 18.2.1 Assessment Methods for a description of the Variety Classes). Important (Variety Class A or B) visual resources on the valley floor include the Sacramento National Wildlife Refuge Complex, which contains the Sacramento National Wildlife Refuge (NWR), Colusa NWR, Delevan NWR, Sacramento River NWR, Sutter NWR, and Butte Sink NWR.

Reservoirs in the region increase the level of scenic attractiveness at their maximum operating levels. Reservoirs are generally Class A or B visual resources when their water surface elevations are near to or at their maximum. As drawdown occurs during the summer and fall, an increasing area of shoreline devoid of vegetation, commonly referred to as a "bathtub ring", appears in the area between the normal high water mark and the actual lake level. The exposed rock and soil of the drawdown zone contrasts with the vegetated areas above the high water level and with the lake's surface. As a consequence of reservoir operations, the level of scenic attractiveness tends to decline in July and August with increasing drawdown.

Seasonal variations in flow levels of the rivers within this region provide for a wide range of aesthetic opportunities. Most of the rivers in this region have low flow regulations in place. Flow requirements for the various rivers and streams may be found in State Water Resources Control Board water right permits or licenses, Federal Energy Regulatory Commission (FERC) hydropower licenses, and interagency agreements (White 2003). Because there are minimum flow requirements and the flows are managed, riparian vegetation along the rivers reflects the results of current management practices. These practices include levees for flood control, managed floodplains and overflow bypasses, and controlled releases from reservoirs and result in a narrow riparian corridor. None-the-less, riparian vegetation remains an important visual aspect to all streams and river corridors. Water, shade, and dense cover distinguish the riparian areas from the surrounding land. In addition, riparian areas are popular wildlife habitat as they offer food, water, and protection from both the sun and from large-scale human disturbance.

Highways with high viewer sensitivity in the area of analysis include: Interstate 5, Highway 99, and State Routes 70 and 20. Agricultural areas along these highways and other roads in the Central Valley are generally Class C. The following sections describe the visual character of water bodies in the Upstream from the Delta Region.

The only upland elevations in the northern Central Valley upstream from the Delta are 32,000 acres in the Sutter Buttes. Rising from the valley floor, the Sutter Buttes, generally a Class A visual resource, provide visual drama from a wide viewing area.

18.1.2.1 Sacramento River

The Sacramento River originates above Lake Shasta in the north and flows through the Sacramento Valley to the Delta. Agriculture, a Class C visual resource, dominates the land use near the River along the valley floor, while the upper watershed has retained its oak woodland, grasslands, forests, and rural character. Rice is one of the prominent crops grown in the Sacramento Valley and is visibly noticeable along the Interstate 5 corridor. The Sacramento Valley also has many acres of other field crops and orchards.

18.1.2.1.1 Lake Shasta

Lands adjacent to Lake Shasta consist primarily of steep slopes, upland vegetation, and coniferous forests (Class A and B visual resources). Shoreline areas are largely undeveloped and experience summer drawdown zones. The shorelines of Lake Shasta vary from steep and rocky banks to coves of wooded flats. During the summer months, Lake Shasta levels are drawn down creating a ring of bare soils along the lake's high water mark. The ring represents a negative visual feature that affects the overall visual quality of the area.

18.1.2.2 Feather River

The upper, middle, and lower forks of the Feather River originate in Plumas and Lassen Counties. The forks flow south/southwest and join in Lake Oroville, then continue south to the Feather River's confluence with the Sacramento River. Agricultural lands (Class C) are predominant near the Feather River in its lower reaches, while upper reaches of the three forks have visual resources typical of the Sierra foothills (Class A and B visual resources).

The lower Feather River terrain is generally flat. Riparian vegetation lines the river, with grassland and croplands in the adjacent agricultural areas. Along the southern portion of the Feather River, near Marysville, large areas of rice fields, as well as other field crops are located.

18.1.2.2.1 Little Grass Valley and Sly Creek Reservoirs

Little Grass Valley Reservoir, at an elevation of 5,046 feet in the Plumas National Forest, comprises 16 miles of shoreline. The shoreline offers a variety of wildlife viewing opportunities for birds and mammals. Sly Creek Reservoir is located in eastern Butte County, 35 miles east of Oroville. The area has a combination of coniferous and hardwood trees. Campgrounds, picnic areas, and other developed recreation areas all provide views to Little Grass Valley and Sly Creek Reservoirs.

During the summer months, the reservoir's levels are drawn down to create a ring of bare soils beneath the high water mark. The ring represents a negative visual feature that affects the overall visual quality of the area. In general; however, the Little Grass Valley and Sly Creek Reservoirs have both Class A and B visual resources.

18.1.2.2.2 Lake Oroville

Dams, reservoirs, and related facilities are among the most visually important elements within the Lake Oroville landscape and its vicinity. Although the scenery in the foothill region around the facilities is attractive, it is generally of local and regional importance, not state or national importance. The State recreation area at Lake Oroville has Class A and B visual resources.

The Lake Oroville Visitor Center, on the crest of Kelley Ridge, includes a 47-foot high observation tower designed to provide panoramic views of the dam and reservoir. Many of the most immediate views of the reservoir are from marinas, boat launch areas, campgrounds, picnic areas, and other developed recreation areas surrounding the reservoir. During the summer months, Lake Oroville levels are drawn down to create a ring of bare soils beneath the lake's high water mark. The ring represents a negative visual feature that affects the overall visual quality of the area.

18.1.2.3 Yuba River and New Bullards Bar Reservoir

The Yuba River's north, middle, and south forks originate in the Sierra Nevada. The north and middle forks of the Yuba River meet and join downstream of New Bullards Bar Reservoir, and the south fork joins just upstream of Englebright Lake. The confluence of the Yuba and Feather Rivers is near Marysville. The terrain along the north and south forks of the Yuba River consists of large areas of pine trees intermixed with small pockets of hardwood and barren land (Class A or B visual resources). The middle fork of the Yuba River has very similar terrain features, but small pockets of annual grassland are intermixed within the terrain. Grassland, agricultural fields, as well as some areas of barren land (Class C visual resources), surround the Lower Yuba River as it flows toward the Feather River near Marysville.

18.1.2.3.1 New Bullards Bar Reservoir

New Bullards Bar Reservoir is located on the north fork of the Yuba River, approximately 21 miles north of Nevada City. Conifers and mixed hardwoods surround the reservoir. Cliffs of red, clay-like soil are also found in areas around the reservoir. These variations offer the visitor a variety of landscape views. A marina, trail, and campgrounds provide public access and viewing opportunities. Adjacent county roads also provide viewing opportunities of New Bullards Bar Dam and Reservoir. During the summer months, New Bullards Bar Reservoir levels are drawn down to create a ring of bare soils below the reservoir's high water mark. The ring represents a negative visual feature that affects the overall visual quality of the area. In general, however, the reservoir has both Class A and B visual resources.

18.1.2.4 American River

18.1.2.4.1 Upper American River

The upper American River flows through steep valleys with large expanses of exposed granite found most often in higher elevations. Some of these canyon walls drop as much as 1,000 feet vertically in places. Most of the areas along the north fork of the American River are occupied by pine, with the some steep hillsides occupied by oak and chaparral communities (PCWA 2001). The north fork of the American River is a federally designated Wild and Scenic River, and is a Class A visual resource.

The environment at the confluence of the north and middle forks of the Upper American River is characterized by two canyons that converge into a single canyon. The river flows through the canyon about 2,000 to 4,000 feet below the rim. These features combine to create a landscape of high visual quality.

18.1.2.4.2 French Meadows and Hell Hole Reservoirs

French Meadows Reservoir, in Placer County, has a picturesque shoreline that consists of many varieties of trees and shrubs, as well as wildflowers. This vegetation provides suitable habitat for many wildlife species, and opportunities for wildlife viewing.

Source: SWRI

Figure 18-2
Hell Hole Reservoir

Hell Hole Reservoir is located in the Eldorado National Forest and has a 15-mile shoreline of rugged canyon walls that make it very picturesque, as shown in Figure 18-2. The reservoir's clear water adds to the visual character of the landscape and the shoreline is suitable for wildlife and bird viewing.

French Meadows and Hell Hole Reservoirs are both Class A and B visual resources. During the summer months, the water surface elevations in both French Meadows and Hell Hole Reservoirs are drawn down to create a ring of bare soil below the reservoir's high water mark. The ring represents a negative visual feature that affects the overall visual quality of the area.

18.1.2.4.3 Folsom Lake

Folsom Lake contrasts sharply with the nearby rolling grassland and wooded foothill landscapes. During the summer months, Folsom Lake levels are drawn down to create a ring of bare soils below the lake's high water mark. The ring represents a negative visual feature that affects the overall visual quality of the area. Folsom Lake, however, generally creates a pleasing visual setting for recreational uses (PCWA 2001). Lake Natoma, which is just downstream from Folsom Lake, is surrounded by

gravel banks, large boulders, and riparian vegetation that provide an attractive landscape for visitors. Folsom Lake and Lake Natoma have both Class A and B visual resources.

18.1.2.4.4 Lower American River

The lower American River provides a variety of visual experiences, including steep bluffs, terraces, islands, backwater areas, and riparian vegetation. The water surface, gravel banks, natural grasses, smaller plants, and a variety of trees along the river create a natural setting designated as a "protected area" in the American River Parkway Plan by Sacramento County for native plant restoration and habitat protection (PCWA 2001). The American River reach through Sacramento is a federally designated Wild and Scenic River.

The portion of the river from Nimbus Dam to the Gristmill Dam Recreation Area (approximately two miles upstream of the Watt Avenue Bridge) is viewed most frequently by passing motorists at bridge crossings. This unit is considered to be the most sensitive visual portion of the lower American River. The lower American River is generally considered a Class A visual resource.

18.1.2.5 Merced River

The south fork of the Merced River is a federally designated Wild and Scenic River and considered a Class A visual resource. It enters the mainstem of the Merced River near South Fork, CA. The mainstem of the Merced River then flows west, through Lake McClure, out of the foothills, and into the surrounding area consisting mainly of farmland (Class C).

Class C features along the Merced River corridor include field crops, fruit and nut trees, and vegetables. Other Class C agricultural land uses, such as dairies and poultry farms, are also scattered throughout the corridor.

18.1.2.5.1 Lake McClure

Lake McClure is located in the Sierra Nevada Foothills in Mariposa County. The lake has 80 miles of shoreline and is surrounded by pine and oak woodlands. Lake McClure has many areas suitable for bird and wildlife viewing. The reservoir typically has Class A and B visual resources. During the summer months, the lake is drawn down to create a ring of bare soils below the lake's high water mark. The ring is a negative visual feature of the lake.

18.1.3 Delta

A large portion of the Delta is devoted to farming. The region is interlaced with a network of waterways and levees designed to protect the Delta's islands and tracts. Major visual resources in the Delta Region include the state recreation areas of Franks Tract, Brannon Island, and Windy Cove; Stone Lakes NWR; the Consumnes-Mokelumne River confluence wildlife preserve; and several private marinas, camping, and fishing sites. SR 160 is a state-designated scenic highway from Antioch

to Freeport. Representative Scenic Classes A and B resources viewed from the Delta include Mount Diablo in Contra Costa County and the Vaca Range in Napa and Solano Counties.

The main roads from which travelers can view the Delta are State Route 160, 4, and 12. In many sections of State Route 4 and 12, it is impossible to view the Delta waterways, but elevated features such as Mount Diablo can be seen. Delta waterways including rivers, creeks, and sloughs are visible primarily from boats, which use the Delta for commerce and recreation.

18.1.4 Export Service Area

The Export Service Area encompasses the San Joaquin Valley, Santa Clara Valley, and southern California. The San Joaquin Valley is predominantly centered upon agriculture (cotton, dairy, safflower, wheat, and citrus orchards), urban environments (such as Fresno and Bakersfield), and mountainous terrain (Coastal Range, Tehachapi Mountains, and southern California Ranges). As with the Sacramento Valley, broad, sweeping panoramas of agricultural fields, interspersed with regional infrastructure (roads and canals) and a variety of urbanized areas characterize views within the San Joaquin Valley today. Highways in the surrounding areas with high viewer sensitivity include 152, 33, 5, 68, and 75. Many of these highways follow routes near the lakes and reservoirs within the area that are defined by the surrounding rolling hills such as those found in the Los Angeles National Forest.

Historical changes from grasslands and extensive marsh areas to cropland and orchards have changed the visual variety in the Central Valley. The valley floor is primarily irrigated agriculture that is a Class C visual resource. Important (Scenic Class A or B) visual resources on the valley floor include the San Luis National Wildlife Refuge Complex (the San Luis and Merced NWRs), which is located in the northern San Joaquin Valley in what is known as the Grasslands Ecological Area. This 160,000-acre area contains a third of the wetlands remaining in the Central Valley of California, and includes the Los Banos, Volta, and North Grasslands wildlife areas (California Dept. of Fish and Game), Great Valley Grasslands State Park (California Dept. of Parks and Recreation), and over 100 privately-owned duck clubs.

The Santa Clara Valley is a flat, gently sloping valley floor surrounded by the low, rolling to steep foothills of the Diablo Range to the east and the Santa Cruz Mountains and Gabilian Range to the west.

Southern California is characterized by urban areas such as Los Angeles and San Diego, the Mojave and other deserts, coastal scrub, and forested mountains. The topography ranges from sea level at the coast to almost 9,000 feet in the San Gabriel Mountains.

18.1.4.1 Anderson Reservoir

Anderson Reservoir is located in the Coyote Creek watershed of the Mt. Hamilton foothills just east of the City of Morgan Hill in Santa Clara County. The surrounding terrain is characterized by steep, undeveloped hillsides covered by a mix of grassland, oak, chaparral vegetation, with occasional pine trees. Land use is open space, public access parks, rangeland, and watershed. There are several residences within the immediate vicinity of the reservoir. Because the reservoir is used for water storage and flood control, it experiences seasonal changes in water levels creating a broad drawdown zone by early fall.

18.1.4.2 San Luis Reservoir

San Luis Reservoir is nestled in the grassy hills of the western San Joaquin Valley near historic Pacheco Pass. The reservoir's 23,551-acre recreation area provides boating, fishing, boardsailing, camping, and picnicking. In the spring the golden-brown hills surrounding the reservoir are coated with an ephemeral coating of green, highlighted by bursts of wildflower colors. A visitor center at the Romero Overlook offers information on the reservoir and provides telescopes for viewing the area around the reservoir. The groundwater recharge basins nearby, such as the San Luis Rey basin, provide habitat and viewing opportunities for waterfowl and water birds.

18.1.4.3 Diamond Valley Lake

Diamond Valley Lake, between Temecula and Hemet, is 4.5 miles wide. The lake has a 285-foot high dam on its west side and a 185-foot high dam on its east side. Public access to this lake begins in 2003 and will include picnic grounds, overlook sites, a trail for biking, hiking, and riding, and wildlife and vegetation viewing.

18.1.4.4 Lake Perris

Lake Perris, southeast of Los Angeles, has 10 miles of shoreline with picnic sites and trailheads that provide for hiking and viewing opportunities. Lake Perris also serves as a sanctuary to observe wildlife. Ducks and geese winter at the lake and shorebirds flock there most of the year. Birds of prey and upland birds inhabit the surrounding grasslands and mountains.

18.1.4.5 Castaic Lake

Castaic Lake is in the Castaic Mountains in southern California and comprises 29 miles of shoreline that supports a variety of tree, shrubs, and wildflower species. The 425-foot tall Castaic Dam attracts many visitors. Castaic Lagoon, south of Castaic Lake, features sandy beaches and grassy picnic areas.

18.1.4.6 Lake Mathews

Lake Mathews is in Riverside County and is part of the Estelle Mountain Reserve, which consists of approximately 4,000 acres formally designated as a State Ecological Reserve. The Reserve encompasses the largest block of open, natural and semi-natural land in western Riverside County (Center for Natural Lands Management 2003). Flat grasslands and sage scrub surround Lake Mathews; rolling hills, the Santa Ana mountains, and Monument Peak provide backdrop.

18.2 Environmental Consequences/Environmental Impacts

18.2.1 Assessment Methods

Under each alternative, the EWA agencies would negotiate contracts with willing sellers based on a number of factors, including price, water availability, and location. These factors would change from year-to-year; therefore, the EWA agencies may choose to vary the acquisition strategy in each year. To provide maximum flexibility, this analysis includes many potential transfers that the EWA agencies would not likely need in a given year. Chapter 2 defines the transfers that are included in this analysis.

Because the nature of landscape analysis is very subjective, visual resource analyses are generally qualitative. In this analysis, the assessment methods are guided by the Scenery Management System (SMS) developed by the United States Department of Agriculture, Forest Service (USDA FS) in 1995 and outlined in *Landscape Aesthetics: A Handbook for Scenery Management, Agriculture Handbook Number 701*. The SMS is an evolved and updated version of the Visual Management System. While the essence of the system remains unchanged, the SMS allows for improved integration of aesthetics with other biological, physical, and social/cultural resources in the planning process. This assessment describes the effects of EWA acquisitions on known sensitive visual resources and landscapes in the area of analysis. The analysis discusses the effects of stored reservoir water, groundwater substitution, source shifting, and crop shifting/idling. Effects are evaluated based on the significance criteria described in Section 18.2.2. The SMS is applied to the EWA program using the following steps:

- **Identify visually sensitive areas.** Sensitivity is considered highest for views seen by people driving to or from recreational activities, or along routes designated as scenic corridors. Views from relatively moderate to high-use recreation areas are also considered sensitive.

- **Define the landscape character.** Landscape character gives an area its visual and cultural image, and consists of the combination of physical, biological, and cultural attributes that make each landscape identifiable or unique. Landscape character refers to images of the landscape that can be defined with a list of scenic attributes. A description of landscape character is provided in Section 18.1, Affected Environment, for each of the visually sensitive areas identified.

- **Classify Scenic attractiveness.** Scenic attractiveness classifications are a key component of the SMS and are used to classify visual features into the following categories (USDA FS 1995):

    - Class A - "distinctive": Areas where landform, vegetation patterns, water characteristics, and cultural features combine to provide unusual, unique, or outstanding scenic quality. These landscapes have strong positive attributes of variety, unity, vividness, mystery, intactness, order, harmony, uniqueness, pattern, and balance.

- Class B - "typical": Areas where landform, vegetation patterns, water characteristics, and cultural features combine to provide ordinary or common scenic quality. These landscapes generally have positive, yet common, attributes of variety, unity, vividness, mystery, intactness, order, harmony, uniqueness, pattern, and balance.

- Class C – "indistinctive": Areas where landform, vegetation patterns, water characteristics, and cultural land use have low scenic quality. Often water and rock form of any consequence are missing in Class C landscapes. These landscapes have weak or missing attributes of variety, unity, vividness, mystery, intactness, order, harmony, uniqueness, pattern, and balance.

Class A and B resources typically include state or federal park, recreation, or wilderness areas. Rivers and reservoirs are typically considered Class A or B visual resources. Class C resources generally include areas that have low scenic quality and contain more common landscapes, such as agricultural lands. Landscape character is provided in Section 18.1, Affected Environment, for each of the visually sensitive areas identified.

18.2.2 Significance Criteria

Three significance criteria are used for this analysis. An impact on a visual resource would be potentially significant if implementing an action would:

1. Obstruct or permanently reduce visually important, Scenic Class A and B features that can be viewed from visually sensitive areas.

2. Result in long-term (that is, persisting for 5 years or more) adverse visual changes or contrasts to the existing landscape as viewed from areas with high visual sensitivity within 3 miles.

3. Adversely affect landscape character and scenic attractiveness of Class A and B visual resources.

A river would be adversely affected visually if the decrease in flow resulted in exposure of the riverbed, reduction of riparian vegetation along the banks, or changes to any important visual features of the river. An adverse visual effect to reservoirs would occur if surface water elevation levels decreased to a level such that shoreline riparian vegetation were reduced or the "bathtub" ring was substantially larger than under the existing conditions.

18.2.3 Environmental Consequences/ Environmental Impacts of the No Action/No Project Alternative

The analysis of the visual resources during the assessment period (Stage 1 phase of the CALFED plan) indicated that there would be no changes in visual resources from that described in the Affected Environment/Existing Conditions section. The No Action/No Project Alternative would not include construction action resulting from

not implementing the EWA. In addition, the No Action/No Project Alternative would not change ongoing Central Valley Project (CVP)/State Water Project (SWP) water delivery operations. Any effects on visual resources relating to lowered reservoir levels and decreased river flows would be the same under the future Project operations. Therefore, the No Action/No Project Alternative reflects that of the affected environment description and is termed Baseline Condition in the following sections. The No Action/No Project Alternative would have no effect on visual resources.

18.2.4 Environmental Consequences/Environmental Impacts of the Flexible Purchase Alternative

The EWA does not involve construction, introduction of new scenic features, or activities that would visually change the landscape for more than one season. Therefore, there would not be any visual effects of EWA acquisitions relating to the first two significance criteria listed in Section 18.2.2. EWA actions, however, could result in temporary changes or seasonal changes in the landscape. Therefore, effects could occur relating to the third significance criteria in Section 18.2.2. This analysis describes these potential effects to landscape in the area of analysis.

The Flexible Purchase Alternative allows acquisitions of up to 600,000 acre-feet and does not specify limits for acquisitions from the Upstream from the Delta Region or the Export Service Area within the 600,000 acre-feet maximum. The maximum transfer from the Upstream from the Delta Region would be between 50,000 and 540,000 acre-feet (assuming carriage water loses), depending on hydrologic year and conveyance capacity through the Delta. Although the use of all potential acquisition methods would probably not occur in a single year, this section discusses all transfers to provide effects analysis of the maximum transfer scenario.

The environmental consequences on visual resources of stored reservoir water, groundwater substitution, crop idling, and source shifting are discussed by water body. If no visual environmental consequences have been associated with an acquisition type, the acquisition type is not discussed. All changes to surface water elevations and flows are in comparison to the Baseline Condition. Refer to Appendix H for modeling results.

EWA agencies could potentially negotiate multi-year transfers with willing water agencies. Multi-year transfers would have the same effects on visual resources as those described in the Flexible Purchase Alternative analysis.

18.2.4.1 Upstream from the Delta Region

EWA acquisition of water in Butte, Colusa, Glenn, Placer, Sutter, and Yolo Counties via crop idling would result in temporary conversion of lands from rice crops to dry fields during the summer growing season. A portion of this area's rice acreage, near Interstate 5 and Highway 99, are visible to large numbers of viewers. The specific locations where rice farmland idling will occur is not known so it is not known if the idled land will be visible to the general public. Rice acreage (agricultural land) is generally considered a

Class C visual resource. Each year, some portions of the existing rice acres are normally idled, creating a patchwork of flooded and dry fields. EWA crop idling actions would increase the amount of dried fields during the summer months to a maximum of 20 percent total rice acreage in each county, or 47,980 acres for the entire Upstream from the Delta Region. EWA actions would not affect the Class C rating of rice acreage because idling only changes the mosaic pattern of farmland practices and does not add a new visual feature to the landscape. Therefore, there would be no effect to the character of the landscape or visual attractiveness in the area, and the visual effect would be less than significant.

Waterfowl use flooded agricultural land during the summer for brood, cover, and rearing habitat and during migratory periods and winter for cover and forage. During the winter, large numbers of waterfowl can occasionally be observed in rice fields, increasing the visual attractiveness of the area. Because EWA actions would only occur during the summer months, and rice fields are normally flooded during late fall through early spring (due either to rainfall or site preparation flooding), EWA actions would not affect wildlife viewing opportunities. Furthermore, in the summer, the dry fields can create upland habitats suitable for raptors and their prey, increasing a potential for viewing different types of wildlife. Because crop idling is not a permanent practice, this effect would be less than significant. No mitigation is required.

18.2.4.1.1 Sacramento River

EWA acquisition of Sacramento River Contractor water via groundwater substitution and crop idling would decrease Sacramento River flows from Lake Shasta downstream to its diversion pumps in June[1]. EWA acquisition of up to 120,000 acre-feet of water via groundwater substitution and up to 158,000 acre-feet from crop idling would decrease flows by 1,160 cubic feet per second (cfs) in June. The reduction from 18,180 cfs to 17,020 cfs represents a minimal decrease in median monthly flow and would not result in a visual effect. The Sacramento River is generally considered a Class B visual resource. The decreases in flow would be insufficient to reduce the riparian vegetation corridor along the river. Therefore, because the minimal percent reduction of flow and the temporary nature of the decrease would not change the character of the landscape or detract from the overall scenic attractiveness of the Sacramento River, this effect would be less than significant. No mitigation is required.

EWA acquisition of Sacramento River contractor water via groundwater substitution and crop idling would increase Sacramento River flows downstream from Lake Shasta in July through September. EWA acquisition of up to 120,000 acre-feet of water via groundwater substitution and up to 158,000 acre-feet from crop idling would increase Sacramento River flows by 240 cfs between Lake Shasta and the point of diversion in July. Flows in this reach would decrease 133 cfs and 111 cfs in August and September, respectively. Downstream from the diversion point, flows would increase by 289 cfs,

[1] Because of flow and temperature requirements in the Sacramento River, Lake Shasta would not be able to store EWA water from groundwater substitution and crop idling in April and May. During these months, flows in the Sacramento River would be the same as under the Baseline Condition. In some years, (depending on hydrologic conditions) Lake Shasta would store EWA water in June.

372 cfs, 429, cfs, 1,940 cfs, 777 cfs, and 157 cfs April through September, respectively. This represents a 1 to 11 percent increase in flow. An increase in flow could contribute to the character of the landscape; therefore, there would be no adverse effect. No mitigation is required.

Lake Shasta

EWA acquisition of Sacramento River contractor water via groundwater substitution and crop idling would change the timing of releases from Lake Shasta. Lake Shasta would hold back at most, 68,900 acre-feet of water that would have been released under the Baseline Condition. The lake level would decline faster in July and August compared to Baseline Conditions; however, end of month elevation in September would be the same as the Baseline Condition because of reduced releases during September. Lake Shasta elevation would be 1.1 feet lower in July, 0.5 of a foot lower in August, and equal to the Baseline Condition in September (Figure 14-5; Chapter 14). Differences of these magnitudes relative to the Baseline Condition would not change the character of the landscape or scenic attractiveness (Class A or B) of Lake Shasta. The existing "bathtub" rings, under the Baseline Condition would be large enough that an additional drop of less than 2 feet would not result in any significant visible effects. Reduction of surface water elevation also would have minimal effect on the visual features of riparian vegetation along the banks; therefore, this effect would be less than significant. No mitigation is required.

18.2.4.1.2 Feather River

Sly Creek and Little Grass Valley Reservoirs

EWA acquisition of Oroville-Wyandotte Irrigation District (ID) stored reservoir water would decrease surface water elevations from December until refill for Sly Creek and Little Grass Valley Reservoirs. EWA acquisition of up to 15,000 acre-feet of stored reservoir water would decrease surface water elevation by a maximum of 12 feet in Little Grass Valley Reservoir (Figure 14-6) and a maximum of 17 feet from December until refill of Sly Creek Reservoir (Figure 14-7). According to the refill criteria (Chapter 4), the reservoirs would refill in the wet season from December through May in most years, but some of that water would need to be released downstream during the late summer if the water used to refill has been used by the CVP/SWP downstream.

Under the Baseline Condition, median reservoir levels show that Sly Creek Reservoir fluctuates 106.3 feet, which creates a large "bathtub ring" when the reservoir is drawn down. Similarly, Little Grass Valley Reservoir fluctuates 30 feet under the Baseline Condition. The EWA would draw down the reservoirs past the Baseline Condition, causing the bathtub rings to be slightly larger during the early winter months. The existing rings; however, are large enough that an additional drop (17 feet and 12 feet) would not affect any Class A or B scenic features of Sly Creek and Little Grass Valley Reservoirs. The visual effects of the decrease in elevation would only be temporary and only apparent during the winter months because the reservoirs would refill within a few months of the transfer. Therefore, there would be little effect to Class A or B visual resources of the reservoirs and thus the effect would be less than significant. No mitigation is required.

Lake Oroville

EWA acquisition of water from Western Canal WD, Joint Water District Board, and Garden Highway MWC via crop idling and groundwater substitution would increase the surface water elevation from April to June and decrease the surface water elevation in July and August in Lake Oroville compared to the Baseline Condition. EWA agencies would acquire 110,000 acre-feet through groundwater substitution and 126,550 acre-feet through crop idling. During April through June, Lake Oroville would hold back water that would have been released under the Baseline Condition. By the end of June, the surface water elevation in the reservoir would be, at most, 2 feet higher than under the Baseline Condition (Figure 14-8; Chapter 14). Increased releases in July and August would cause the lake level to decline faster compared to the Baseline Condition; however, reduced releases in September would allow the end of month elevation in September to be the same as the Baseline Condition. Under the Baseline Condition, the "bathtub" ring of Lake Oroville is visually noticeable. The EWA would result in the "bathtub" ring becoming larger during July and August, although, by September the ring would be the same size as under the Baseline Condition. Therefore, there would be little visual effect to the "bathtub" ring or shoreline vegetation. Thus, there would be little effect to Class A or B visual resources of Lake Oroville and this effect would be less than significant. No mitigation is required.

18.2.4.1.3 Yuba River

EWA acquisition of Yuba River Contractor water via groundwater substitution would decrease Yuba River flows from April to June. EWA acquisition of water via groundwater substitution would decrease flows by 239 cfs from April to June between Yuba County WA's power facility discharge (just upstream of Englebright Reservoir) and the users' diversion points, typically at Englebright or Daguerre Point Dam). Because flow reductions below the Englebright Dam would be minor and temporary, the character of the landscape would not change and the overall scenic attractiveness of the Yuba River would remain intact. The visual character of riparian vegetation along the river corridor would not be affected, and a decrease in flow would cause little affect to Class A or B visual resources. This effect would be less than significant. No mitigation is required.

EWA acquisition of Yuba River Contractor water via groundwater substitution would increase Yuba River flows in June through September. Yuba River flows would increase at most by 1,005 cfs in July through September; approximately 60 percent above the Baseline Condition. An increase in flow would contribute to the character of the landscape of the resource; therefore, there would be adverse effect.

New Bullards Bar Reservoir

EWA acquisition of water from Yuba County Water Agency (Yuba County WA) via stored reservoir water and groundwater substitution would alter the surface water elevation from April to refill at New Bullards Bar Reservoir. EWA acquisition of up to 85,000 acre-feet of water from groundwater substitution would increase water levels in New Bullards Bar Reservoir while the water is held back until the Delta pumps are available. EWA acquisition of 100,000 acre-feet of stored reservoir water from New Bullards Bar Reservoir would decrease water levels, with the release of water starting at the same

time that the water from groundwater substitution is released. Figure 14-9 illustrates the combined effects of these two transfers on the reservoir. The combination of these releases would reduce lake levels compared to the Baseline Condition by 1 foot, 10 feet, and 24 feet in July, August, and September, respectively. In October, the drawdown zone would be greater than under the Baseline Condition, but not greater than the maximum potential drawdown zone. This visual effect would cause little affect to Class A or B scenic features of the Yuba River. Therefore, effects to visual resources would be less than significant. No mitigation is required.

18.2.4.1.4 American River

EWA acquisition of Placer County WA stored reservoir water would increase Middle Fork of the American River flows downstream from Oxbow Powerhouse to Folsom Lake from June through October. Releases would increase relative to the Baseline Condition. An increase in flow could contribute to the character of the landscape of the resource; therefore, there would be no adverse effect.

EWA acquisition of Placer County WA stored reservoir water would decrease American River flows downstream from French Meadows Reservoir to Folsom Lake during refill of Hell Hole and French Meadows Reservoirs. River flows would decrease during the winter and early spring. During the winter, the river is already at a time of high flows under the Baseline Condition. A decrease in flow that could occur under the EWA would not result in any change to Class A or B visual resources[2]. This area would not be considered visually sensitive because recreation is limited and many people would not view the area; therefore, this effect would be less than significant. No mitigation is required.

EWA acquisition of Sacramento Groundwater Authority's water via stored groundwater purchase would increase American River flows downstream from Folsom Lake from June through December. The EWA agencies would help to determine when and at what rate this water would be released to provide instream fishery benefits as well as to transfer it across the Delta. An increase in flow would contribute to the landscape character of the resource; therefore, this effect would be less than significant. No mitigation is required.

Hell Hole and French Meadows Reservoirs

EWA acquisition of Placer County WA stored reservoir water would decrease surface water elevations from June to refill at Hell Hole and/or French Meadows Reservoirs. EWA acquisition of up to 20,000 acre-feet of stored reservoir water would decrease surface water elevation by a maximum of approximately 8 feet in French Meadows Reservoir (Figure 14-10) and in Hell Hole Reservoir by a maximum of approximately 14 feet from July until refill (Figure 14-11). Under the Baseline Condition, median reservoir levels show that Hell Hole Reservoir fluctuates 110 feet, which creates a large "bathtub ring" when the reservoir is drawn down. Similarly, French Meadows Reservoir fluctuates 60 feet in a median year under the Baseline Condition. The EWA

[2] The decrease in flows cannot be predicted quantitatively because it is unknown how the reservoirs would refill.

would draw down the reservoirs past the average low level exhibited under the Baseline Condition, causing the bathtub rings to be more extensive. The existing rings; however, are large enough that an additional drop would not significantly alter the landscape character or detract from the scenic attractiveness of the reservoirs. There would be little change to Class A or B visual resources of Hell Hole and French Meadows Reservoirs; therefore, the effects to visual resources from the reservoir decreases would be less than significant. No mitigation is required.

Folsom Lake

EWA acquisition of Sacramento Groundwater Authority's water via stored groundwater purchase and Placer County Water Agency's water via stored reservoir water would change surface water elevations in Folsom Lake. During July and August, the surface water elevation at Folsom Lake would be 0.8 of a foot lower than under the Baseline Condition. End of month elevation in September would be the same as under the Baseline Condition because of reduced releases during September (Figure 14-12; Chapter 14). The small changes in surface water elevation would have little affect on Class A or B visual resources of Folsom Lake; therefore, any visual effect would be less than significant. No mitigation is required.

18.2.4.1.5 Merced River

EWA acquisition of Merced ID water via groundwater substitution would decrease Merced River flows downstream from New Exchequer Dam to the point of diversion from April through September. Merced River flows in this reach would decrease by approximately 70 cfs. Long-term average Merced River flows below Crocker Huffman Dam under the Baseline Condition are 500 cfs, 894 cfs, and 881 cfs in April, May and June, respectively. A decrease of 70 cfs in flow would be insufficient to affect the visual character of riparian vegetation along the river corridor. Under the Baseline Condition, flows during July through September are less than 330 cfs. Therefore, a decrease of 70 cfs in flow would result in little change to Class A or B visual resources of the Merced River and the effect would be less than significant. No mitigation is required.

Lake McClure

EWA acquisition of Merced ID water via groundwater substitution would increase the water surface elevation in Lake McClure compared to the Baseline Condition. EWA agencies could acquire 25,000 acre-feet through groundwater substitution. During April through September, Lake McClure would hold back water that would have been released under the Baseline Condition. By the end of September, the surface water elevation in the reservoir would be, at most, 3 feet higher than under the Baseline Conditions (Figure 14-13). An increase in water surface elevations would improve the overall scenic attractiveness of Lake McClure and reduce the visibility and size of a "bathtub ring". Therefore, there would be no adverse effect. No mitigation is required.

18.2.4.2 Delta

There would be no decreases in Delta inflows from the Sacramento or San Joaquin Rivers under the Flexible Purchase Alternative; however, Delta exports would increase. EWA acquisition would not result in any effect to Class A or B visual

resources in the Delta. The character of the landscape and the level of scenic attractiveness would not change from the Baseline Conditions; therefore, the effect to visual resources would be less than significant. No mitigation is required.

18.2.4.3 Export Service Area

EWA acquisition of water in Fresno, Kern, Kings, and Tulare Counties via crop idling would result in temporary conversion of cotton fields to bare fields. A portion of the cotton acreage is near Interstate 5 and is visible to large numbers of viewers. Farmers rotate crops regularly, leaving a portion of the fields idle most years. EWA actions would increase

Source: CDM

Figure 18-3
Cotton Field Idled for Two Years with Regular Discing

the number of acres of idled land. Dust suppression measures, including use of a winter wheat cover crop, would reduce some of the visual change caused by cotton crop idling. The visual change from cotton land (Class C) to idled field (Class C, see Figure 18-3) would result in a minor visual change to a Class C resource (farmland). Because the character of the landscape would not change and the level of scenic attractiveness would remain as Class C, the effect to visual resources would be less than significant. No mitigation is required.

Anderson Reservoir

EWA source shifting of project water from San Luis Reservoir would decrease surface water elevations in Anderson Reservoir whereas EWA pre-delivery of water from San Luis Reservoir would increase surface water elevations. Santa Clara Valley Water District operates Anderson Reservoir for normal water supply, emergency water supply, and for flood control within the Coyote Creek drainage. The District maintains a minimum pool amount of 20,000-acre feet. The District would not be involved in any source shifting action that would decrease amounts to less than the minimum pool. Although source shifting may lower the surface elevation earlier than normal in a season, it would not cause a visual effect greater than that experienced as part of normal operations. Pre-delivery would result in an increased surface water elevation reducing the visual

effect of the drawdown zone. In either case, EWA source shifting or pre-delivery would have a less than significant effect on the visual quality of Anderson Reservoir.

San Luis Reservoir

EWA borrowed project water from San Luis Reservoir would decrease surface water elevations. Surface water levels in San Luis Reservoir would decrease earlier in the year. EWA actions may cause attaining low-point levels earlier in the year than under the Baseline Condition. The EWA assets would be managed to prevent the EWA action from causing or aggravating any low point problems in San Luis Reservoir. A decrease in surface water levels earlier in the year would not result in an adverse change to the existing landscape character or detract from the overall scenic attractiveness because the surface water levels in San Luis Reservoir typically vary during the summer under the Baseline Condition. EWA actions would not result in any change to Class A or B visual resources of San Luis Reservoir; thus, the effect to visual resources as a result of decrease in surface water levels would be less than significant. No mitigation is required.

Diamond Valley Lake, Lake Perris, Castaic Lake, and Lake Mathews

EWA Source shifting would decrease the summer surface water elevation at Diamond Valley Lake, Lake Perris, Castaic Lake, and Lake Mathews. Source shifting would not affect Class A or B visual resources because water levels in the reservoir would remain within the annual operating levels. Although source shifting may lower the surface elevation earlier than normal in a season, it would not cause a visual effect greater than that experienced as part of normal operations. EWA source shifting would have a less than significant effect on the visual quality of these reservoirs and is thus considered less than significant. No mitigation is required.

18.2.5 Environmental Consequences/Environmental Impacts of the Fixed Purchase Alternative

The Fixed Purchase Alternative specifies purchases of 35,000 acre-feet from the Upstream from the Delta Region, and 150,000 acre-feet from the Export Service Area. While the amounts in each region are fixed, the acquisition types and sources could vary. In this section, the effects of each potential transfer are analyzed to allow the EWA agencies maximum flexibility when negotiating purchases with willing sellers. These transfers are the same actions as those described for the Flexible Purchase Alternative, but the amounts are limited by the total acquisition amount in each region (35,000 acre-feet from the Upstream from the Delta Region and 150,000 acre-feet from the Export Service Area). The following sections evaluate the effects of the Fixed Purchase Alternative.

18.2.5.1 Upstream from the Delta Region

EWA acquisition of water in Butte, Colusa, Glenn, Placer, Sutter, and Yolo Counties via crop idling would result in temporary conversion of lands from rice crops to dry fields during the summer growing season. A portion of this area's rice acreage, near Interstate 5 and Highway 99, are visible to large numbers of viewers. The specific locations where rice farmland idling will occur is not known so it is not known if the idled land will be

visible to the general public. Rice acreage (agricultural land) is generally considered a Class C visual resource. Each year, some portions of the existing rice acres are normally idled, creating a patchwork of flooded and dry fields. EWA crop idling actions would increase the amount of dried fields during the summer months to a maximum of 20 percent total rice acreage in each county, or a maximum of 34,770 acres for the entire Upstream of the Delta Region. EWA actions would not affect the Class C rating of rice acreage because idling only changes the mosaic pattern of farmland practices and does not add a new visual feature to the landscape. Therefore, there would be no effect to the landscape character or visual attractiveness in the area, and the visual effect would be less than significant.

Waterfowl use flooded agricultural land during the summer for brood, cover, and rearing habitat and during migratory periods and winter for cover and forage. During the winter, large numbers of waterfowl can occasionally be observed in rice fields, increasing the visual attractiveness of the area. Because EWA actions would only occur during the summer months, and rice fields are normally flooded during late fall through early spring (due either to rainfall or site preparation flooding), EWA actions would not affect wildlife viewing opportunities. Furthermore, in the summer, the dry fields can create upland habitats suitable for raptors and their prey, increasing a potential for viewing different types of wildlife. Because crop idling is not a permanent practice, this effect would be less than significant. No mitigation is required.

18.2.5.1.1 Sacramento River

EWA acquisition of Sacramento River Contractor water via groundwater substitution and crop idling would decrease Sacramento River flows from Lake Shasta downstream to its diversion pumps in June. EWA acquisition of up to 35,000 acre-feet of water via groundwater substitution or up to 35,000 acre-feet from crop idling would decrease monthly Sacramento River flows by 180 cfs in June. The reduction from 18,180 cfs to 18,000 cfs in June would not result in affects to Class A or B visual resources and there would be no noticeable effect to Lake Shasta water levels. Crop idling would be limited to less than 20 percent of all rice farmland in each county. The effects to visual resources would therefore be less than significant. No mitigation is required.

EWA acquisition of Sacramento River contractor water via groundwater substitution and crop idling would increase Sacramento River flows downstream from Lake Shasta in July through September. EWA acquisition of up to 35,000 acre-feet of water via groundwater substitution and up to 35,000 acre-feet from crop idling would increase Sacramento River flows by 240 cfs between Lake Shasta and the point of diversion in July. An increase in flow could contribute to the character of the landscape; therefore, there would be no adverse effect.

Lake Shasta

EWA acquisition of Sacramento River contractor water via groundwater substitution and crop idling would change the timing of releases from Lake Shasta. Lake Shasta would hold back at most, 9,000 acre-feet of water that would have been released under the Baseline Condition. The lake level would decline faster in July and August compared to

Baseline Conditions; however, end of month elevation in September would be the same as the Baseline Condition because of reduced releases during September. Differences of these magnitudes relative to the Baseline Condition would not change the landscape character or scenic attractiveness (Class A or B) of Lake Shasta. Surface elevation reductions would not result in any significant visible effects on the existing "bathtub" rings. Reduction of surface water elevation also would have minimal effect on the visual features of riparian vegetation along the banks; therefore, this effect would be less than significant. No mitigation is required.

18.2.5.1.2 Feather River

Sly Creek and Little Grass Valley Reservoirs

EWA acquisition of Oroville-Wyandotte ID stored reservoir water would decrease surface water elevations from December until refill for Sly Creek and Little Grass Valley Reservoirs.. The EWA agencies would acquire stored reservoir water from Sly Creek Reservoir and Little Grass Valley Reservoir in November and December before fish actions are likely. An equivalent amount of water could be sold to the EWA agencies under the Fixed Purchase Alternative, as is described under the Flexible Purchase Alternative. Refer to Section 18.2.4.1.2, Feather River, for a discussion of potential effects on surface elevation fluctuations in Sly Creek and Little Grass Valley Reservoirs. Water acquisition requires no mitigation as there are potentially few effects to Class A and B scenic features. The effect on visual resources under the Flexible Purchase Alternative is less than significant; the effect is also less than significant for the Fixed Purchase Alternative.

EWA acquisition of water from Western Canal WD, Joint Water Districts, and Garden Highway MWC via crop idling and groundwater substitution would increase the surface water elevation from April to June and decrease the surface water elevation in July and August in Lake Oroville compared to the Baseline Condition. EWA would acquire up to 35,000 acre-feet of water via groundwater substitution or up to 35,000 acre-feet from crop idling. During April through June, Lake Oroville would hold back as much as 17,900 acre-feet of water that would have been released under the Baseline Condition. Surface elevations would increase during the holding time and decrease slower during release in July and August. Surface elevation fluctuations would not change the landscape character and would not detract from the scenic attractiveness of the visual resources around Lake Oroville. There would be less change in surface water elevation under the Fixed Purchase Alternative than under the Flexible Purchase Alternative. Because there were no significant effects under the Flexible Purchase Alternative, there would also be no significant effects under the Fixed Purchase Alternative.

18.2.5.1.3 Yuba River

EWA acquisition of Yuba River Contractor water via groundwater substitution would decrease Yuba River flows from April to June. Yuba River flows would decrease by 195 cfs in late spring as farmers use groundwater for irrigation instead of surface water from New Bullards Bar Reservoir. The decrease in flow would not affect the character of the landscape or overall scenic attractiveness of the land. A decrease in flow would

not affect Class A or B visual resources; therefore, the effect to visual resources would be less than significant. No mitigation is required.

EWA acquisition of Yuba River Contractor water via groundwater substitution would increase Yuba River flows in June through September. In June through September, flows would increase downstream from New Bullards Bar with an additional release of 195 cfs. An increase in flow could contribute to the character of the landscape; therefore, there would be no adverse effect. No mitigation is required.

New Bullards Bar

EWA acquisition of water from Yuba County WA via stored reservoir water and groundwater substitution would alter the surface water elevation from April to refill at New Bullards Bar Reservoir. Groundwater substitution would increase water levels in New Bullards Bar Reservoir while the water is held back until the Delta pumps are available. Beginning in June, New Bullards Bar would release, at a maximum, 35,000 acre-feet of water to be used as an EWA Asset. The release would reduce surface elevations by a maximum of 8 feet compared to the Baseline Condition. The fluctuations in surface water elevation at New Bullards Bar Reservoir would not be substantial enough to change the character of the landscape and would not detract from the scenic attractiveness. Therefore, the effect to the visual resources from EWA acquisition of Yuba County WA stored reservoir water would be less than significant. No mitigation is required.

18.2.5.1.3 American River

EWA acquisition of Placer County WA stored reservoir water would increase Middle Fork of the American River flows downstream from Oxbow Powerhouse to Folsom Lake from June through October. The same amount of water could be transferred under the Fixed Purchase Alternative as described in the Flexible Purchase Alternative. Refer to Section 18.2.4.1.4 for a discussion of potential effects. An increase in flow could contribute to the character of the landscape of the resource; therefore, there would be no adverse effect. No mitigation is required.

EWA acquisition of Placer County WA stored reservoir water would decrease American River flows downstream from French Meadows Reservoir to Folsom Lake during refill of Hell Hole and French Meadows Reservoirs. The same amount of water could be transferred under the Fixed Purchase Alternative as described in the Flexible Purchase Alternative. Refer to Section 18.2.4.1.4 for a discussion of potential effects. The effects of the Flexible Purchase Alternative would be less than significant; the effects of the Fixed Purchase Alternative would also be less than significant.

EWA acquisition of Sacramento Groundwater Authority's water via stored groundwater purchase would increase American River flows downstream from Folsom Lake from June through December. The same amount of water could be transferred under the Fixed Purchase Alternative as described in the Flexible Purchase Alternative. Refer to Section 18.2.4.1.4 for a discussion of potential effects. An increase in flow would contribute to the character of the landscape; therefore, there would be no adverse effect. No mitigation is required.

Hell Hole and French Meadows Reservoirs

EWA acquisition of Placer County WA stored reservoir water would decrease surface water elevations from June to refill at Hell Hole and/or French Meadows Reservoirs. EWA acquisition of up to 20,000 acre-feet of stored reservoir water would decrease surface water elevation by a maximum of approximately 8 feet in French Meadows Reservoir (Figure 14-10) and in Hell Hole Reservoir by a maximum of approximately 14 feet from July until refill (Figure 14-11). The same amount of water could be transferred under the Fixed Purchase Alternative as described in the Flexible Purchase Alternative. Refer to Section 18.2.4.1.4 for a discussion of potential effects. Effects to visual resources would be less than significant. No mitigation is required.

Folsom Lake

EWA acquisition of Sacramento Groundwater Authority's water via stored groundwater purchase and Placer County Water Agency's water via stored reservoir water would change surface water elevations in Folsom Lake. During July and August, the surface water elevation at Folsom Lake would be 0.8 of a foot lower than under the Baseline Condition. The same amount of water could be transferred under the Fixed Purchase Alternative as described in the Flexible Purchase Alternative. Refer to Section 18.2.4.1.4 for a discussion of potential effects. Effects to visual resources would be less than significant. No mitigation is required.

18.2.5.1.5 Merced/San Joaquin Rivers

EWA acquisition of Merced ID water via groundwater substitution would decrease Merced River flows downstream from New Exchequer Dam to the point of diversion from April through June. Merced River flows would decrease by approximately 70 cfs. An equivalent amount of water could be sold to the EWA agencies under the Fixed Purchase Alternative, as is described under the Flexible Purchase Alternative. Refer to Section 18.2.4.1.5, Merced River, for a discussion of potential effects. The effects of the Flexible Purchase Alternative would be less than significant; the effects of the Fixed Purchase Alternative also would be less than significant. No mitigation is required.

EWA acquisition of Merced ID water via groundwater substitution would increase the water surface elevation in Lake McClure compared to the Baseline Condition. EWA agencies could acquire 25,000 acre-feet through groundwater substitution. Lake McClure would hold back water and surface water elevation would increase. An increase would contribute to the character of the lake; therefore, there would be no adverse effect. No mitigation is required.

18.2.5.2 Delta

There would be no decreases in Delta inflows from the Sacramento or San Joaquin rivers under the Fixed Purchase Alternative; however, Delta exports would increase. There would be little effect to Class A or B visual resources of the Delta; therefore, this effect would be considered less than significant. No mitigation is required.

18.2.5.3 Export Service Area

EWA acquisition of water in Fresno, Kern, Kings, and Tulare Counties via crop idling would result in temporary conversion of cotton fields to bare fields. A portion of the cotton acreage is located near Interstate 5, and is visible to large numbers of viewers. Total crop idling would be limited to less than 20 percent of all cotton farmland in each county. The visual change from cotton land (Class C) to idled field (Class C, see Figure 18-2) would result in minor adverse visual changes to a Class C resource (farmland). Since the change in scenic attractiveness would be minimal, this effect would be less than significant. No mitigation is required.

Anderson Reservoir

EWA source shifting of project water from San Luis Reservoir would decrease surface water elevations in Anderson Reservoir whereas EWA pre-delivery of water from San Luis Reservoir would increase surface water elevations. Santa Clara Valley Water District operates Anderson Reservoir for normal water supply, emergency water supply, and for flood control within the Coyote Creek drainage. The District maintains a minimum pool amount of 20,000-acre feet. The District would not be involved in any source shifting action that would decrease amounts to less than the minimum pool. Although source shifting may lower the surface elevation earlier than normal in a season, it would not cause a visual effect greater than that experienced as part of normal operations. Pre-delivery would result in an increased surface water elevation reducing the visual effect of the drawdown zone. In either case, EWA source shifting or pre-delivery would have a less than significant effect on the visual quality of Anderson Reservoir.

San Luis Reservoir

EWA borrowed project water from San Luis Reservoir would decrease surface water elevations. Surface water levels in San Luis Reservoir would decrease earlier in the year. The existing "bathtub ring" would be large enough that an additional decrease would not detract from the overall scenic attractiveness of the reservoir. Furthermore, the reservoir levels typically vary during the summer under the Baseline Condition. Therefore, a decrease in surface water levels earlier in the year would not affect any Class A or B visual resources of San Luis Reservoir, and the effects would be less than significant. No mitigation is required.

Diamond Valley Lake, Lake Perris, Castaic Lake, and Lake Mathews

EWA source shifting would decrease the summer surface water elevation at Diamond Valley Lake, Lake Perris, Castaic Lake, and Lake Mathews. The effects as described for the Flexible Purchase Alternative in Section 18.2.4.3 for source shifting at these reservoirs would be the same as under the Fixed Purchase Alternative. Therefore, the effect on visual resources would be less than significant. No mitigation is required.

18.2.6 Comparative Analysis of Alternatives

This section has thus far analyzed the effects of many potential transfers, looking at the "worst-case scenario" that would occur if all acquisitions happened in the same year. This approach ensures that all effects of transfers are included, and provides the EWA Project Agencies the flexibility to choose transfers that may be preferable in a

given year. The EWA; however, would not actually purchase all of this water in the same year. This section provides information about how EWA would more likely operate in different year types.

In the Upstream from the Delta Region, the Fixed Purchase Alternative would be limited to a maximum acquisition of 35,000 acre-feet from all sources of water. This amount could typically be obtained from stored reservoir water purchases in most year types. In very dry years, stored reservoir water may not be available, and the EWA would need to look to other sources. These sources would probably be groundwater substitution first and crop idling second. Therefore, in most years under the Fixed Purchase Alternative, the primary visual resource effect would be at the reservoirs (Class A and B visual resources). In very few years would there be an agriculture (Class C visual resource) related visual effect.

The Flexible Purchase Alternative could involve the purchase of up to 600,000 acre-feet of water from all sources in the Upstream from the Delta Region. EWA agencies would prefer to purchase water from upstream sources because the water is generally less expensive. The amount that could be purchased would be limited by the capacity of the Delta export pumps to move the water to export areas south of the Delta. During wet years, excess pump capacity may be limited to as little as 60,000 acre-feet of EWA asset water because the pumps primarily would be used to export state and federal project water to export service area users. During dry years, when there would be less Project water available for pumping (and therefore the pumps would have greater available capacity), the EWA Project Agencies could acquire up to 600,000 acre-feet of water from sources in the Upstream from the Delta Region. Therefore, in dry years, EWA acquisitions by all methods would have a potential for affecting visual resources related to reservoirs (Class A and B) and agricultural land (Class C). Table 18-1 compares the Flexible and Fixed Purchase Alternatives to the Baseline Condition.

The EWA Project Agencies usually prefer to purchase stored reservoir water because it is the least expensive option. In dry years for the Fixed Purchase Alternative, EWA Project Agencies would likely purchase all stored reservoir water available, and then look to other options for the remainder of its purchases. The effects on visual resources would be greater during these years. In wet years, a portion of the stored reservoir water available would likely provide the entire amount of water that could be moved through the Delta. During these years the effects on visual resources would be less striking.

The potential for effects on visual resources during wet and dry years for the Flexible Purchase Alternative would be very similar to the Fixed Purchase Alternative because stored reservoir water would be utilized before any other assets.

Table 18-1
Comparison of the Effects of the Flexible and Fixed Purchase Alternatives on Visual Resources

Region	***Asset Acquisition or Management***	***Result***	***Effects***	***Flexible Alternative Change from the Baseline Condition***	***Fixed Alternative Change from the Baseline Condition***	***Significance of Flexible Alternative***	***Significance of Fixed Alternative***

	Crop Idling	Conversion of rice fields to barren land	Reduced rice acreage in Placer County	Idling a maximum of 3,280 acres	Idling a maximum of 3,280 acres	LTS	LTS
Merced/San Joaquin River	Stored groundwater Purchase Flexible & Fixed: 25 TAF	Water is held in Lake McClure	Slower decrease in water levels in Lake McClure in April through October, compared to non-EWA conditions.	Lake McClure increases by a maximum of 25,000 acre-feet	Lake McClure increases by a maximum of 25,000 acre-feet	LTS	LTS
			Merced River flows decrease April – October.	Merced River flow decreases by 70 cfs	Merced River flow decreases by 70 cfs	LTS	LTS
Delta Region	Crop idling, Groundwater substitution, Stored groundwater purchase, Stored reservoir water	Water is released from reservoirs	Increased Delta exports July – September	Delta exports increase by a maximum of 2,118 cfs.	Delta exports increase by a maximum of 245 cfs.	LTS	LTS

Table 18-1
Comparison of the Effects of the Flexible and Fixed Purchase Alternatives on Visual Resources

Region	Asset Acquisition or Management	Result	Effects	Flexible Alternative Change from the Baseline Condition	Fixed Alternative Change from the Baseline Condition	Significance of Flexible Alternative	Significance of Fixed Alternative
Export Service Area	Source Shifting	Water is drawn from SWP, SCVWD, and MWD reservoirs	Decreased water levels in Anderson, Castaic, Perris, Mathews and Diamond Valley	Water levels decreased by 200,000 acre-feet total for all reservoirs.	Water levels decreased by 200,000 acre-feet total for all reservoirs.	LTS	LTS
	Borrowed Project Water	Water is released from San Luis Reservoir	Decreased water levels in San Luis Reservoir	San Luis Reservoir water levels would reach the low point at the same time as under the Baseline Condition.	San Luis Reservoir water levels would reach the low point at the same time as under the Baseline Condition.	LTS	LTS
	Crop Idling	Conversion of cotton lands to barren fields	Reduced cotton acreage in the Export Service Area	Idling a maximum of 182,800 cotton acres	Idling a maximum of 177,300 cotton acres	LTS	LTS

18.2.7 Mitigation Measures

Under each of the acquisition types and alternatives no adverse effects would occur from the Fixed and Flexible Purchase Alternatives to the visual resources found within the area of analysis. Therefore, no mitigation measures would be required.

18.2.8 Potentially Significant Unavoidable Impacts

There would be no potentially significant unavoidable impacts associated with the Fixed Purchase Alternative and Flexible Purchase Alternative.

18.2.9 Cumulative Effects

18.2.9.1 Upstream from the Delta Region

The Sacramento Valley Water Management Agreement, Dry Year Purchase Program, Drought Risk Reduction Investment Program, CVP Improvement Act Water Acquisition Program, and Environmental Water Program include water acquisitions upstream from the Delta. These programs all include stored reservoir water, and many include other acquisition types such as groundwater substitution, groundwater purchase, and crop idling. These programs, in addition to the EWA, could magnify the effects described under the Flexible Purchase Alternative.

The Environmental Water Program would purchase water from different facilities than the EWA; therefore, there would be no potential for a cumulative decrease in surface water elevation in reservoirs resulting in adverse visual effects. The Sacramento Valley Water Management Agreement, Dry Year Purchase Program, and Drought Risk Reduction Investment Program, as well as other potential water transfers, could purchase water from the same reservoirs as the EWA. Other programs in combination with the EWA that purchase water from the same selling agency could draw down reservoirs further than analyzed in this chapter. The additional water sold for other programs would reduce the Baseline Condition as described and could cause significant effects. A cumulative effect would only be considered significant if the combined program acquisitions surpassed the significance criteria. If all water acquisition programs purchased water from the same source, a cumulative visual effect could occur. Because the Project Agencies would have some involvement in non-EWA water acquisition programs due to the need to use SCP and/or SWP facilities to export the water, EWA agencies would have the opportunity to assess cumulative effects and not purchase water from a water agency if a cumulative effect would occur. Therefore, EWA would not have an incremental effect to the cumulative condition.

Actions such as groundwater substitution and crop idling in the Upstream from the Delta Region would potentially occur in four out of the five cumulative programs. These actions, in addition to the EWA, would create changes in the timing and quantity of water released from reservoirs, altering river flows. Water transfers from other agencies along the same rivers as in the EWA program area could also contribute to a cumulative effect on the change in river flow. EWA agencies would

not purchase water from a water agency if a cumulative effect would occur. Therefore, EWA would not have an incremental effect to the cumulative condition.

18.2.9.2 Export Service Area

Only the Drought Risk Reduction Investment Program and the CVPIA Water Acquisition Program operate in the Export Service Area. Any water acquired through crop idling would not be a permanent action and would involve a Class C visual resource. Therefore, increased crop idling from various programs would not produce a cumulatively significant effect to visual resources.

Chapter 19
Environmental Justice

The concept of environmental justice embraces two principles: 1) fair treatment of all people regardless of race, color, nation of origin, or income and 2) meaningful involvement of people in communities potentially affected by program actions. Executive Order 12898, Section 2-2, signed by President Clinton in 1994, requires all Federal agencies to conduct "programs, policies, and activities that substantially affect human health or the environment, in a manner that ensures that such programs, policies, and activities do not have the effect of excluding persons (including populations) from participation in, denying persons the benefits of, or subjecting persons to discrimination because of their race, color or national origin". Section 1-101 requires Federal agencies to identify and address, as appropriate, "disproportionately high and adverse human health or environmental effects" of programs on minority and low-income populations.

State law defines environmental justice in Government Code Section 65040.12(e) as the fair treatment of people of all races, cultures, and incomes with respect to the development, adoption, implementation, and enforcement of environmental laws, regulations, and policies. Government Code Section 65040.12(a) designates the Governor's Office of Planning and Research (OPR) as the coordinating agency in State government for environmental justice programs, and requires OPR to develop guidelines for incorporating environmental justice into general plans.

The Bay Delta Public Advisory Committee (BDPAC) has an Environmental Justice Subcommittee composed of Federal and State agency representatives, tribal members, community-based organizations, advocacy groups, and others interested in achieving environmental justice. As set forth by the Record of Decision (ROD), CALFED agencies are committed to addressing environmental justice challenges related to water management in the Bay-Delta. The purpose of the BDPAC environmental justice subcommittee is to provide advice and guidance to BDPAC to ensure that implementation of the CALFED Bay-Delta Program actions provides benefits to minority, low-income, tribal or other potentially affected communities. The subcommittee works to meet its goal through the implementation of a strategy that requires collaboration and support from each CALFED Program Element. The subcommittee meets on a regular basis, at various locations throughout the State to provide meaningful public participation to interested communities, stakeholders, and others impacted by CALFED program activities.

EWA agencies could acquire water through stored groundwater, groundwater substitution, stored reservoir water, or through crop idling. Of these actions, only crop idling could affect farm labor employment and other individuals involved in farming (including farm supply companies, custom operators, and related businesses). The agribusiness industry employs wage earners of all income levels and of all ethnic compositions. The concern for environmental justice is that minority and low income persons would be disproportionately affected.

Crop idling would involve not irrigating crops for a season and transferring the unused irrigation water to the Environmental Water Account (EWA). Workers on the farms would need to find alternative employment - an effort that could be hampered by their level of education, English speaking ability, and unfamiliarity with local employment services.

Ninety-three percent of workers on farms are of Hispanic origin and earn a median annual personal income between $7,500 and $10,000. They typically possess a sixth grade education (Rosenberg et al 1998). These identifying factors place these workers into a low income, minority group that will represent the environmental justice community – a community who could bear the greatest burden of crop idling. The remainder of this chapter will focus on workers on farms whose jobs are lost by crop idling.

19.1 Affected Environment/Existing Conditions

EWA agencies incorporated rice and cotton for crop idling in the EWA project description for four basic reasons:

1) These crops require greater amounts of water per acre than most other crops;

2) There are adequate acreages of these crops that can provide the quantities of water needed by the EWA;

3) Farmers have expressed willingness to provide water and idle their land; and

4) These crops typically require less labor than other crops.

Table 19-1 shows the amount of labor required to grow 1000 acres of commonly grown, annual crops[1] and the amount of water required for each crop throughout the growing season. The amount of water is also referred to as the estimated evapotranspiration of applied water (ETAW). ETAWs change as the science for generating the values improves.

Wheat and various types of silages require less labor than either cotton or rice; however, acreages are not available in quantities that could supply the amount of water required by the EWA. Cotton in the Upstream from the Delta Region could also appear to be a potential selection; however, the number of acres devoted to this crop in the Upstream of the Delta Region limits the ability to make water transfers sufficiently large for the EWA.

[1] Potential crops for idling do not include orchards, pasture, or alfalfa crops because water consumption cannot be readily metered. Common crops in the program area are those with the largest amount of acreages within the counties. Full time labor equivalents represent the number of full time individuals required to produce 1000 acres of a crop throughout a season. Full time labor equivalents are determined by the amount of machine and nonmachine labor required for each crop.

Table 19-1
Labor and Water Requirements per Common Crop

Crop		*Full Time Labor Equivalents*	*ETAW*
Upstream from the Delta[1] (Butte, Colusa, Glenn, Placer, Sutter, and Yolo Counties)	Rice	2.7	3.3
	Cotton[2]	5.0	2.3
	Beans	5.9	1.5
	Corn	6.2	1.8
	Wheat	1.6	0.5
	Tomatoes	20.4	1.8
	Safflower	2.5	0.7
Export Service Area (Fresno, Kern, Kings, and Tulare counties)	Cotton	6.6	2.3
	Corn for Grain[3]	6.2	2.0
	Safflower	2.5	2.0
	Wheat	1.6	1.0
	Corn Silage	1.6	2.0
	Wheat Silage	1.2	1.2
	Carrots	5.5	1.4
	Cantaloupe	14.5	1.4
	Alfalfa Silage[4]	1.5	3.1
	Tomatoes	20.4	2.1

(1) ETAWS from Jerry Johns, DWR, January 5, 2002, Water Transfers Based on Crop Shifting and Crop Idling – How to Make Them Work
(2) Less than 11,000 acres of cotton available only in Colusa County.
(3) Scott Hayes, Land and Water Use Analyst, DWR, November 2002, 1995 DWR ETAWs. Less than 70,000 acres "field crops unspecified" (CAC 2002) available in Kings County only (Vernon, 2002)
(4) Less than 60,000 acres "silage" (CAC 2002) available in Tulare county (Schoenborn, 2002)

EWA water transfers are consistent with guidelines contained within the CALFED Water Transfer Program. The CALFED Water Transfer Program is a framework of actions, policies, and processes that facilitate, encourage, and streamline a properly regulated and protective water market which will allow water to move between users, including environmental uses, on a voluntary and compensated basis. The Water Transfer Program has a set of criteria that helps facilitate a protective market, or one that protects both those directly and indirectly involved in the water transfer transaction. Specifically, water transferees are encouraged to consider beneficial and adverse impacts on the fiscal integrity of districts and on the economy of agricultural communities in source and receiving areas. Policy-level recommendations of the CALFED Program are based upon the objectives and criteria of the Water Transfer Program.

EWA agencies factored into the project description the rationale for crop selection. Furthermore the project description limits EWA water acquisitions from idling to no more than 20 percent of recent harvested rice or cotton acreage in a county (refer to Section 11.2.8 for consideration of other water acquisition programs). EWA Project Agencies would gather accurate data regarding the amount of crop acreage previously harvested and idled in participating counties. The data are available from DWR Land Use Surveys, the USDA, and county crop reports. This information would be confirmed by the local Farm Bureau, local UCCE offices, the Agricultural Commissioners Office, or other crop specific authorities. Data collection and

confirmation strengthens the consistency between EWA and the Water Transfer Program.

The measures incorporated into the EWA project description are consistently applied in multi-year crop idling contracts. These stipulations would seek to maintain the current economic and social conditions.

The tables below provide background data on ethnic compositions (Table 19-2), and poverty and unemployment rates (Table 19-3) for counties in the Upstream from the Delta Region and the Export Service Area. Table 19-2 shows that on average, the Export Service Area is 44.2% Hispanic.

Table 19-2
Ethnicities by Region

	Upstream from the Delta Region	***Export Service Area***
Hispanic	24.1%	44.2%
White	74.1%	57%
Asian	5.3%	4.5%
African American	1.2%	5.3%
American Indian/Alaska Native	1.7%	1.6%
Native Hawaiian/Pacific Islander	0.2%	0.2%

Source: U.S. Census Bureau. Mapstats, 2000; values do not equal 100% due to multi-race reporting

Poverty rates are expressed as a percentage of households in the county living at the poverty level or below. The U.S. Census Bureau defines poverty thresholds (levels of income) for families of various sizes and compositions. Unemployment rates are expressed as the percent of the civilian labor force (all civilians 16 years of age and over) that is unemployed.

As shown in Table 19-3, U.S. Census data reveals that counties comprising the Export Service Area average a 24.5 percent poverty rate. In the Upstream from the Delta Region, the poverty rate is 16.6 percent[2]. Unemployment in Export Service Area counties in which EWA acquisitions could occur is 13.6%; unemployment in the Upstream from the Delta counties is 9.1%.

[2] The U.S. Census Bureau calculates information on poverty levels from forms requesting family size and income sent to one in every six households. In 1999, an annual income of $19,882 represented the U.S. Census Bureau poverty threshold for a family of five including three related children under 18 years of age; a single individual under 65 who earned $8,667 annually lived at the Federal poverty level. In California the poverty level for a family of five is a little higher, ranging between $22,940 and $24,160 (EDD 1999). Rosenberg, et al, (1998) describe average farmworkers as married with an average of 3 children, constituting a family of five.

Table 19-3 Average Poverty and Unemployment Levels		
	Upstream from the Delta Counties	Export Service Area
Poverty Rate[1]	16.6%	24.5%
Unemployment[2]	9.1%	13.6%

Figure 19-1
Environmental Justice Area of Analysis

19.1.1 Area of Analysis

Consistent with corresponding portions in this EIS/EIR, the Environmental Justice Chapter divides the State into two regions: the Upstream from the Delta Region and the Export Service Area. EWA agencies are considering rice idling in Butte, Colusa, Glenn, Placer, Yolo, and Sutter in the Upstream from the Delta Region. They are also considering crop idling in Fresno, Kern, Kings, and Tulare in the Export Service Area. The boundaries of each county in each region define the Upstream from the Delta Region and the Export Service Area (refer to Figure 19-1).

19.1.2 Upstream from the Delta Region

Table 19-4 and 19-5 provide ethnic compositions, unemployment, and poverty rates for Upstream from the Delta counties.

Table 19-4 Ethnicities in Upstream from the Delta Counties						
County	Caucasian (%)	African-American (%)	American Indian/ Alaska Native (%)	Asian-American (%)	Native Hawaiian/ Pacific Islander (%)	Hispanic (%)
Butte	84.5	1.4	1.9	3.3	0.1	10.5
Colusa	64.3	0.5	2.3	1.2	0.4	46.5
Glenn	71.8	0.6	2.1	3.4	0.1	29.6
Placer	88.6	0.8	0.9	2.9	0.2	9.7
Sutter	67.5	1.9	1.6	11.3	0.2	22.2
Yolo	67.7	2.0	1.2	9.9	0.3	25.9

19.2 Environmental Consequences/Environmental Impacts

Farmworkers affected by crop idling represent the community of concern for environmental justice in this analysis. This analysis defines disproportionate effects as effects that exceed a proportionate distribution of 50:50, which is defined as farmworker jobs affected over the total agricultural jobs affected by EWA. The remainder of this chapter discusses this relationship.

19.2.1 Assessment Methods

Although the environmental justice approaches contained within Executive Order 12898, *Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations*, and California Government Code Section 65040.12 differ, the underlying intention of both regulations is the fair and equal treatment of all races, cultures, and incomes. The following text includes a statistical analysis that incorporates U.S. Census Bureau information, poverty rates, and ethnic compositions, as recommended by Executive Order 12898. The statistical analysis provides evidence of a social change associated with the EWA, yet the findings consider not only the statistical conclusions but also the more basic issue of whether the EWA Program is consistent with fair treatment of all races, cultures, and incomes.

This analysis assumes a worst-case scenario for crop idling conditions. In actual conditions, water contract negotiations would rely on a number of water acquisition options, as described in Chapter 2. Underlying each transaction is a number of factors that include price, water availability, and location. These factors change from year-to-year; therefore, the EWA Project Agencies would vary their acquisition strategy in each year. With the intent of providing the EWA Project agencies the greatest flexibility, the following text describes the maximum potential effect of idling in both the Upstream from the Delta Region and Export Service Area.

California Environmental Quality Act (CEQA) Guidelines provide guidance in determining Environmental Justice effects. CEQA Guidelines Section 15382 does not recognize an economic or social change as a significant effect, but social change may be considered as it relates to determining the significance of a physical change. For the purposes of this document, both quantitative and qualitative methods were used to evaluate whether the EWA Program would result in fair and equal treatment.

The analysis quantifies the effects on farmworkers using University of California Cooperative Extension (UCCE) crop budgets and county-level EWA crop idling acreage limits (Chapter 11). The UCCE crop budgets provide the number of full-time farmworkers needed for every 1,000 acres of productive rice and cotton farmland. The number is then multiplied by the number of acres that would be idled to provide an estimate of the maximum number of farmworkers displaced through EWA crop idling. The UCCE crop budgets do not count migrant workers; therefore, estimated labor effects may be conservative.

The findings of proportionality rely heavily on one main ratio:

> The total number of farmworkers and the total number of agriculturally-related jobs affected by EWA. (Chapter 11, Regional and Agricultural Economics, employs the IMPLAN model to derive the total number of jobs affected by EWA crop idling.)

This ratio is supported by the percentage of total farmworkers in the county affected by EWA, which is defined as total number of farmworker jobs lost by EWA of the total number of farmworkers in the county.

The total farmworker population, for the purposes of this analysis, uses the general "rule of thumb" adopted by local farm labor expert Phillip Martin, Ph.D., UCD, which states that between 25-30% of people reported by agricultural employers are not farmworkers. This analysis conservatively reports the number of farmworkers in each county as 70% of 1999 REIS farm employment.

19.2.2 Criteria for Determining Adverse Effects

The following factors will be considered in evaluating the environmental justice effects of the EWA Program:

- Whether there is or will be a direct or cumulative effect on the natural or physical environment that adversely affects a minority or low-income population that is proportionately high or adverse.

- Whether that effect on the natural or physical environment results in an effect on minority or low-income population that is disproportionately high, considering the population levels or income levels of all affected groups.

19.2.3 Environmental Consequences/Environmental Impacts of the No Action/No Project Alternative

The No Action/No Project Alternative describes future conditions during Stage 1 of CALFED, if the EWA did not exist. With the exception of Placer County, the analysis of agricultural production during this assessment period shows that the current practices would remain constant. Farmers would continue to temporarily idle some land due to land practices and market issues, while other farmers would place previously idled land back into production. The continued rotation of these farming practices would cause some fluctuations in agricultural employment, but those changes would be expected to reflect that of the employment fluctuations described in the Affected Environment section.

Additionally, several CALFED and other government sponsored programs would idle land for restoration and habitat purposes. This would permanently take agricultural land out of production. (Refer to Chapter 22, Cumulative Analysis.)

The analysis of agricultural employment in Placer County indicates that urbanization would result in a decline to 1240 farm laborers in 2004 from 1720 employed

farmworkers in 1983 (REIS 1983). The No Action/No Project alternative would not alter this trend and thus, would have no effect on environmental justice issues in the county. The No Action/No Project alternative would have no bearing on positive farm labor employment trends in Colusa, Yolo, Butte, Sutter, Fresno, Kern, and Tulare counties.

19.2.4 Environmental Consequences/Environmental Impacts of the Flexible Purchase Alternative

The Flexible Purchase Alternative allows transfers of up to 600,000 acre-feet and does not specify transfer limits in the Upstream from the Delta Region or the Export Service Area. Crop idling potential in the Upstream from the Delta Region is greater during dry years when Delta availability allows EWA agencies additional capacity for transfers. Crop idling in the Export Service Area would most likely occur during wet years or when stored/banked groundwater would not be available; however, the purchases likely would be more expensive. The Flexible Purchase Alternative could limit crop idling transfers to between 540 and 550 TAF in the Export Service Area during wet years and progressively less during dry conditions. Crop idling decisions also depend upon precipitation in the north and south of the Delta that influence how the State Water Project (SWP) allocates existing resources.

Described below are the effects on farmworkers that may occur with maximum crop idling. The basis for a worst cast scenario analysis is to identify all potential effects and to provide EWA agencies flexibility in negotiating water transfer contracts with willing sellers.

19.2.4.1 Upstream from the Delta Region

Table 19-8 identifies the maximum amount of acreage that could be idled annually in each upstream county, as defined in Chapter 11 Regional and Agricultural Economics. As indicated, acreages represent the 20 percent of the county's rice acreage under 1995 through 1999 conditions.

Table 19-8
Proposed Acreages for Rice Idling –Upstream Areas
Flexible Purchase Alternative

County	*Total Acres of Rice in County*[1]	*Acreage Proposed for Idling*	*Percent of Total Rice Acres to be Idled*
Butte	95,120	19,000	20.0%
Colusa	132,338	26,460	20.0%
Glenn	83,777	16,750	20.0%
Placer	16,379	3,280	20.0%
Sutter	96,722	19,340	20.0%
Yolo	23,822	4,770	20.0%

(1) The figures representing total acres within the counties are based on a five-year average to take into account any recent land trends. The data is taken from the County Agricultural Commissioners Reports from 1995 to 1999.

Rice requires 2.7 full time farm labor equivalents for every 1000 acres (UCCE 1999). The total number of agribusiness laborers affected by crop idling[3] varies in each county. Chapter 11 Regional and Agricultural Economics contains a full account of the total number of agribusiness workers affected by crop idling. The total number of jobs affected in each county varies. The total number of jobs affected by crop idling in Butte County is 30 for every 1000 acres idled; in Colusa County it is 18 for every 1000 acres idled. (Refer to Table 11-30 in Chapter 11 Regional and Agricultural Economics.)

Table 19-9 compares the effects on the number of farmworkers who would lose jobs through EWA crop idling as a proportion of the total number of agribusiness jobs lost by EWA (various income levels and ethnicities comprise agribusiness workers). The table also provides the percentage that compares the total number of farmworkers in the county affected by EWA crop idling. The percentages vary with respect to the number of acres proposed for idling and the number of farmworkers in the county. The largest proportion of farmworkers affected in the Upstream of the Delta Region is in Colusa County where 15 percent of the EWA job losses affect farmworkers. These farmworkers represent 2.7 percent of the total farmworkers in Colusa County.

Table 19-9
EWA Labor Effects in Upstream from the Delta Counties
Flexible Purchase Alternative

County	*Number of County Farmworkers*[(1)]	*Number of Farmworkers' Jobs Lost by EWA*[(2)]	*Total Number of Jobs Lost by EWA*[(3)]	*Proportion of Jobs Affected by EWA that are Farmworkers (percent)*	*Percent of Total County Farm Labor Jobs Lost by EWA*
Butte	3,496	51	570	8.9	1.5
Colusa	2,633	71	476	14.9	2.7
Glenn	2,062	45	385	11.7	2.2
Placer	1,032	9	62	14.5	0.9
Sutter	3,937	52	425	12.2	1.3
Yolo	3,576	13	110	11.8	0.4

(1) REIS, 1999; county farm employment data incorporates Census of Agriculture, the Hired Farm Labor Survey from the National Agriculture Statistical Service (USDA), and Economic Research Service (USDA) wages. The Census of Agriculture offers the most complete geographic coverage of hired and contract farm labor use as measured by labor expenditures, and is currently the only national level data source that offers consistent farm labor information at the county and State level. The data includes hired workers on the farm, bookkeepers, secretaries, and mechanics who are generally not considered to be hired farmworkers. Philip Martin, Ph.D., UCD, nationally recognized local expert on farm labor issues, states as a "rule of thumb" that 25-30% of people reported by agricultural employers are not farmworkers. County Farmworker column represents 70% of REIS farm employment.
(2) Refer to Section 12.2.3
(3) Refer to Section 11.2.5.1.2

[3] Includes farmworkers, agribusiness workers, and others as calculated by the IMPLAN model (Chapter 11).

Crop idling in the Upstream from the Delta Region could contribute to disproportionate unemployment of low-income, minority farmworkers. Although crop idling does result in farmworker job loss, the majority of the loss affects agricultural services (a diverse and multi-faceted industry). Crop idling in the Upstream from the Delta Region results in no disproportionate effect.

19.2.4.2 Export Service Area

Table 19-10 identifies the maximum amount of cotton acreage that would be idled in each county in the Export Service Area.

Table 19-10
Proposed Acreages for Cotton Idling – Export Service Area
Flexible Purchase Alternative

County	*Total Acres of Cotton in County*[1]	*Acreage Proposed for Idling*	*Percent of Total Cotton Acres to be Idled*
Fresno	352,880	70,500	20.0%
Kern	246,616	49,300	20.0%
Kings	222,543	44,500	20.0%
Tulare	92,680	18,500	20.0%

(1) The figures representing total acres within the counties are based on a five-year average to take into account any recent land trends. The data is taken from the County Agricultural Commissioners Reports from 1995 to 1999.

Every 1000 acres of cotton requires 6.6 full time farm labor equivalents (UCCE 1999). Table 19-11 shows the total number of jobs lost and the number of farmworker jobs lost when maximum idling occurs in each Export Service Area county. The table also shows the percentage of all farm labor in each county that is affected by EWA crop idling. The largest proportion of farmworkers affected in the Export Service Area is in Kings County where job losses from EWA crop idling affect farmworkers 44.0 percent of the time. Of the 4,361 farmworkers in Kings County, EWA would affect 6.7 percent.

Crop idling in the Export Service Area could contribute to disproportionate unemployment of low-income, minority farmworkers. Although crop idling does result in farmworker job loss, the majority of the loss does not fall upon farmworkers. Crop idling in the Export Service Area results in no disproportionate effect.

Table 19-11
EWA Labor Effects Export Service Area Counties
Flexible Purchase Alternative

County	Number of County Farmworkers[1]	Number of Farmworkers' Jobs Lost by EWA[2]	Total Number of Jobs Lost by EWA[3]	Proportion of Jobs Affected by EWA that are Farmworkers (percent)	Percent of Total County Farm Labor Jobs Lost by EWA
Fresno	25,161	465	1127	41.2	1.8
Kern	17,126	325	740	43.9	1.9
Kings	4,361	294	668	44.0	6.7
Tulare	17,982	122	276	44.2	0.7

(1) REIS, 1999; county farm employment data incorporates Census of Agriculture, the Hired Farm Labor Survey from the National Agriculture Statistical Service (USDA), and Economic Research Service (USDA) wages. The Census of Agriculture offers the most complete geographic coverage of hired and contract farm labor use as measured by labor expenditures, and is currently the only national level data source that offers consistent farm labor information at the county and State level. The data includes hired workers on the farm, bookkeepers, secretaries, and mechanics who are generally not considered to be hired farmworkers. Philip Martin, Ph.D., UCD, nationally recognized local expert on farm labor issues, states as a "rule of thumb" that 25-30% of people reported by agricultural employers are not farmworkers. County Farmworker column represents 70% of REIS farm employment.
(2) Refer to Section 12.2.3
(3) Refer to Chapter 11.2.5.1.2

Though difficult to quantify and factor into the analysis, farmers would benefit by receiving a more reliable water supply, which could enhance their ability to plan for production. Any financial returns could be invested into various sectors of the agribusiness community, which may result in increased farmworker opportunities.

Public meetings introducing the EWA EIS/EIR will encourage open participation of people of all race, color, and national origin. Diverse involvement accommodates an equitable distribution of EWA benefits. Informational materials regarding EWA crop idling actions will be made accessible and understandable to farmworkers and all members of the public attending the meetings.

19.2.5 Environmental Consequences/Environmental Impacts of the Fixed Purchase Alternative

The Fixed Purchase Alternative would involve the same actions as the Flexible Purchase Alternative, but to a lesser degree. The Fixed Purchase Alternative limits Upstream from the Delta transfers to 35,000 acre-feet and Export Service Area transfers to 150,000 acre-feet likely resulting in less idling upstream and in the Export Service Area. Although it is unlikely that the EWA agencies would rely entirely on crop idling because of other available options, this section discusses the maximum amount of crop idling that can occur in one year under the Fixed Purchase Alternative.

Table 19-12 shows the maximum idling acreages under the Fixed Purchase Alternative. Acreages are less than the Flexible Purchase Alternative in Butte, Sutter, and Fresno Counties. Acreages are consistent with those found in Chapter 11,

Regional and Agricultural Economics, and reflect idling associated with maximum Fixed Purchase Alternative transfers.

Table 19-12
Proposed Acreages for Rice/Cotton Idling for Fixed Purchase Alternative

Region	*County*	*Total Acres of Rice/ Cotton in County*[1]	*Acreage Proposed for Idling*	*Percent of Total Rice/ Cotton Acres to be Idled*
Upstream Region	Butte	95,120	10,600	11.1%
	Colusa	132,338	15,000	11.3%
	Glenn	83,777	15,000	17.9%
	Placer	16,379	3,280	20.0%

	Yolo	23,822	4,770	20.0%
Export Service Area	Fresno	352,880	65,000	18.4%
	Kern	246,616	49,300	20.0%
	Kings	222,543	44,500	20.0%
	Tulare	92,680	18,500	20.0%

(1) The figures representing total acres within the counties are based on a five-year average to take into account any recent land trends. The data is taken from the County Agricultural Commissioners Reports from 1995 to 1999.

19.2.5.1 Upstream from the Delta Region

Table 19-13 shows the number of farmworker jobs lost with maximum crop idling proposed by the Fixed Purchase Alternative. The largest proportion of farmworkers affected in the Upstream from the Delta Region is in Colusa County where farmworkers lose 15.2 percent of the total EWA job loss. This number affects 1.6 percent of the total farmworkers in Colusa County.

Table 19-13
EWA Labor Effects in Upstream from the Delta Region

County	*Number of County Farmworkers*[1]	*Number of Farmworker Jobs Lost by EWA*[2]	*Total Number of Jobs Lost by EWA*[2]	*Proportion of Jobs Affected by EWA that are Farmworkers (percent)*	*Percent of Total County Farm Labor Jobs Lost by EWA*
Butte	3,496	29	318	9.1	0.8
Colusa	2,633	41	270	15.2	1.6

Diverse involvement accommodates an equitable distribution of EWA benefits. Informational materials regarding EWA crop idling actions will be made accessible and understandable to farmworkers and all members of the public attending the meetings.

19.2.6 Comparative Analysis of Alternatives

19.2.6.1 Upstream from the Delta

This section provides an analysis of maximum effects on farmworkers produced by the Fixed and Flexible Purchase Alternatives. In each case, "worst-case scenarios" in a given year identified impacts of maximum reliance on crop idling for water acquisitions. This approach ensures that all effects of transfers are included, and provides the EWA Project Agencies the flexibility to choose transfers that may be preferable in a given year. The EWA, however, would not actually purchase all of this water in the same year. This section provides information about how EWA would more likely operate in different year types.

No Project conditions in the Upstream from the Delta Region indicate that farm labor employment is generally increasing in Colusa, Yolo, Butte, and Sutter counties. Urbanization in Placer County is resulting in a declining trend in farm labor employment levels. These trends are expected to continue during wet and dry years regardless of EWA. The Baseline Condition reflects no disproportionate affects on minority and low-income communities.

In the Upstream from the Delta Region, the Fixed Purchase Alternative would be limited to a maximum acquisition of 35,000 acre-feet from all sources of water. In most years, this amount could be obtained from stored reservoir water purchases. In those years when surface water assets were not available (in part or in total), the EWA agencies would acquire water first from groundwater substitution and/or groundwater purchase, followed by crop idling. Because of other available options, the Fixed Purchase Alternative would not likely require nor involve acquisition of water from crop idling; therefore it would not result in environmental justice effects. However, the analysis provides the maximum number of jobs lost via the Fixed Purchase Alternative, in the unlikely chance that crop idling was the only option available for provision of the entire 35,000 acre-feet of water.

The Flexible Purchase Alternative could involve the purchase of up to 600,000 acre-feet of water from all sources in the Upstream from the Delta Region. EWA agencies would prefer to purchase water from upstream sources because the water is generally less expensive. The amount that could be purchased would be limited by the availability of the Delta export pumps to move the water to export areas south of the Delta. During wet years, pump capacity availability may be limited to as little as 50,000 acre-feet of EWA asset water because the pumps primarily would be used to export State and Federal Project water to Export Service Area users. During dry years, when there would be less Project water available for pumping (and therefore the pumps would have greater availability capacity), the EWA Project Agencies could acquire up to 600,000 acre-feet of water in the Upstream from the Delta Region.

The potential for environmental justice effects during wet years for the Flexible Purchase Alternative would be very similar to the Fixed Purchase Alternative. That is, during wet years, acquisitions would most likely be from stored water sources and

crop idling would not be exercised. However, as rainfall amounts for areas north of the Delta decrease, reflecting dry year conditions, the greater capacity of the export pumps to move EWA assets could result in a greater reliance on crop idling for the additional EWA acquisitions. If the EWA Project Agencies were to acquire 600,000 acre-feet in the Upstream from the Delta Region, they would need to utilize most available sources, which would include stored reservoir water, groundwater substitution, groundwater purchase, and crop idling. Increased crop idling in dry years would increase agricultural worker unemployment in Butte, Colusa, Glenn, and Sutter counties.

19.2.6.2 Export Service Area

No Project conditions in the Export Service Area indicate that farm labor employment is generally increasing in Fresno, Kern, and Tulare counties, yet remains stable in Kings County. These trends are expected to continue during both wet and dry years regardless of EWA. No Project conditions reflect no disproportionate effects on minority and low-income communities.

EWA asset acquisitions in the Export Service Area under the Fixed Purchase Alternative would be limited to 150,000 acre-feet from stored groundwater and crop idling sources. The EWA agencies would purchase stored groundwater first, and then purchase water from crop idling if more is needed. Stored groundwater has finite availability, and 150,000 acre-feet would not likely be available in all years. In years with less stored groundwater availability, EWA agencies would turn to crop idling for the remaining water.

EWA asset acquisitions in the Export Service Area under the Flexible Purchase Alternative would be dependent on the water year type north of the Delta. Export pump availability during wet years would limit the ability of the EWA Project Agencies to move assets through the Delta, requiring reliance on greater purchase amounts from export area sources. During wet years, acquisitions within the Export Service Area could involve up to 600,000 acre-feet of assets. Much of this water would be from crop idling; therefore, environmental justice effects of the Flexible Purchase Alternative are likely to be greater than the Fixed Purchase Alternative, but still not significant.

Table 19-15 (below) reflects the effects on the number of farmworker jobs lost by the Fixed and Flexible Alternative transfers. Water transfers under the Fixed Alternative result in fewer job losses in Butte, Colusa, Glenn, Sutter, and Fresno, yet percentage of effects on farmworkers relatively remains the same.

Table 19-15
Comparison of the Flexible Purchase and Fixed Purchase Alternatives
Environmental Justice

Region	*County*	*Asset Acquisition or Management*	*Result*	*Impacts*	*Flexible Purchase Alternative Job Loss*	*Fixed Purchase Alternative Change*	*Significance of Effects for Flexible Purchase Alternative*	*Significance of Effects for Fixed Purchase Alternative*
Upstream from the Delta Region	Butte	Crop Idling	Conversion of rice crops to bare fields	Reduce rice crop acreage in Butte County	51 farmworker jobs lost; 570 total jobs	29 farmworker jobs lost; 318 total jobs lost	No disproportion-ate effect	No disproportion-ate effect
	Colusa	Crop Idling	Conversion of rice crops to bare fields	Reduce rice crop acreage in Colusa County	71farmworker jobs lost; 476 total jobs lost	41 farmworker jobs lost; 270 total jobs lost	No disproportion-ate effect	No disproportion-ate effect
	Glenn	Crop Idling	Conversion of rice crops to bare fields	Reduce rice crop acreage in Glenn County	45 farmworker jobs lost; 385 total jobs lost	41 farmworker jobs lost; 345 total jobs lost	No disproportion-ate effect	No disproportion-ate effect
	Placer	Crop Idling	Conversion of rice crops to bare fields	Reduce rice crop acreage in Placer County	9 farmworker jobs lost; 62 total jobs lost	9 farmworker jobs lost; 62 total jobs lost	No disproportion-ate effect	No disproportion-ate effect
	Sutter	Crop Idling	Conversion of rice crops to bare fields	Reduce rice crop acreage in Sutter County	52 farmworker jobs lost; 425 total jobs lost	29 farmworker jobs lost; 233 total jobs lost	No disproportion-ate effect	No disproportion-ate effect
	Yolo	Crop Idling	Conversion of rice crops to bare fields	Reduce rice crop acreage in Yolo County	13 farmworker jobs lost; 110 total jobs lost	13 farmworker jobs lost; 110 total jobs lost	No disproportion-ate effect	No disproportion-ate effect
Export Service Area	Fresno	Crop Idling	Conversion of cotton crops to bare fields	Reduce cotton crop acreage in Fresno County	465 farmworker jobs lost; 1127 total jobs lost	429 farmworker jobs lost; 1038 total jobs lost	No disproportion-ate effect	No disproportion-ate effect
	Kern	Crop Idling	Conversion of cotton crops to bare fields	Reduce cotton crop acreage in Kern County	325 farmworker jobs lost; 752 total jobs lost	325 farmworker jobs lost; 752 total jobs lost	No disproportion-ate effect	No disproportion-ate effect
	Kings	Crop Idling	Conversion of cotton crops to bare fields	Reduce cotton crop acreage in Kings County	294 farmworker jobs lost; 668 total jobs lost	294 farmwworker jobs lost; 668 total jobs lost	No disproportion-ate effect	No disproportion-ate effect
	Tulare	Crop Idling	Conversion of cotton crops to bare fields	Reduce cotton crop acreage in Tulare County	122 farmworker jobs lost; 276 total jobs lost	122 farmwworker jobs lost; 276 total jobs lost	No disproportion-ate effect	No disproportion-ate effect

19.2.7 Cumulative Effects

Programs cumulatively considered in conjunction with the EWA are: 1) Sacramento Valley Water Management Agreement, 2) Dry Year Purchase Program, 3) Drought Risk Reduction Investment Program (DRRIP), 4) Central Valley Project Improvement Act (CVPIA) Water Acquisition Program (WAP), 5) Environmental Water Program (EWP), and the Ecosystem Restoration Program (ERP). For details of each program, please see Chapter 22. At this time, the Sacramento Valley Water Management Agreement does not include water acquisition via crop idling and would not contribute to effects on low-income or minority people. The EWP retains the option to incorporate crop idling into the program. The Dry Year Purchase Program and DRIPP would combine into one program upon completion of a programmatic document in October 2004 (Jones 2002). Though the full scope is yet undetermined, it is possible that water acquisition via crop idling in the Export Service Area is possible (Jones 2002). Of additional consideration are future crop idling programs such as the

Westlands Global Land Settlement Program and programs that arise in response to a reduction of Colorado River water.

Cumulative effects analysis for environmental justice focuses on those water acquisition programs involving crop idling in the upstream region during dry years and in the Export Service Area. During dry years, the capacity to transfer water through the Delta increases. Programs that would exercise parallel options are the CVPIA (WAP), the ERP, the EWP, and DRRIP. CVPIA (WAP) purchases water from willing sellers given sufficient quantities are available (Jewel 2002). CALFED agencies developed the EWP to carry out flow-related goals of the ERP. The EWP on behalf of the ERP could purchase agricultural land in the Upstream from the Delta Region for habitat restoration and reduce the demand for farm labor.

Although details are still under negotiation and the final outcome is unclear, Westland Water District, under the Global Land Settlement Program, is planning to permanently idle up to 200,000 acres of drainage-impaired land. Once details of the proposed Global Land Settlement Program become available, it is assumed that there will be a transition period requiring coordination between water acquisition programs and farm labor. EWA agencies would maintain close contact with these counties to determine crop idling potential for the Westland Water District. If unemployment conditions are higher than the EWA baseline presented in this EIS/EIR, EWA agencies may choose to avoid crop idling in the district until unemployment conditions stabilize.

EWA agencies would avoid cumulative effects to farmworkers subsequent to these programs by conducting annual investigations of crop idling conditions in each county and water district before initiating further crop idling discussion. During such investigations the EWA agencies would consider other reasonably, foreseeable transfers by all water transfer programs when determining where to acquire water through crop idling. EWA agencies would then only purchase water from idling 20 percent of the rice land in a county, where this 20 percent would include the other, reasonably foreseeable transfers. Information regarding the amount of idled crop acreage should come from DWR Land Use Surveys, the USDA, and county crop reports. Local Farm Bureaus, UCCE offices, Agricultural Commissioners Offices, or other crop specific authorities could verify the information. With careful coordination, data collection, and verification efforts, crop idling for the EWA would not cumulatively contribute adverse conditions on farm labor.

Chapter 20
Indian Trust Assets

Indian Trust Assets (ITAs) are legal interests in property held in trust by the United States for federally-recognized Indian tribes or individual Indians. Land assets held in trust for individual Indians are more specifically referred to as allotments, or as in the case of allotments created out of public domain lands - Public Domain Allotments (PDAs). An Indian trust has three components: 1) the trustee, 2) the beneficiary, and 3) the trust asset. ITAs can include lands, minerals, federally reserved hunting and fishing rights, federally reserved water rights, and in-stream flows associated with a reservation, rancheria, or PDA. Beneficiaries of the Indian trust relationship are federally-recognized Indian tribes and individual Indians with trust land; the United States is the trustee.

By definition, ITAs cannot be sold, leased, or otherwise encumbered without approval of the United States. The definition and application of the U.S trust relationship has been defined by case law that supports Congressional acts, executive orders, and historic treaty provisions.

Consistent with President Clinton's April 29, 1994, Memorandum, CALFED agencies assess the effect of their programs on tribal trust resources and federally reserved tribal governmental rights and concerns. CALFED agencies are tasked to actively engage federally-recognized tribal governments and consult with such tribes on a government-to-government level. The Department of Interior Departmental Manual Part 512 Chapter 2, Departmental Responsibilities for Indian Trust Resources, ascribes the responsibility for ensuring protection and preservation of ITAs from loss, damage, and unlawful alienation, waste, and depletion to the heads of bureaus and offices. EWA agencies will be responsible for assessing whether Environmental Water Account (EWA) water acquisitions and management options have the potential for affecting ITAs.

It is the general policy of the Department of Interior to carry out activities in a manner that protects ITAs and avoids adverse effects whenever possible (Reclamation Indian Trust Asset Policy, July 2, 1993). EWA agencies have incorporated protective environmental measures into the project description and may invoke mitigation measures that reduce effects to a less than significant level. These measures would ensure compliance with threshold levels of significance documented within this Environmental Impact Statement/ Environmental Impact Report (EIS/EIR). In the event an effect is identified, consultation with affected federally recognized tribal governments proceeds through the EWA agencies, the Bureau of Indian Affairs, the Office of the Solicitor, and the Office of American Indian Trust.

EWA water acquisition and management options include groundwater substitution, stored reservoir water, crop idling, groundwater purchase, and source shifting. Water purchase agreements are structured to recognize local leadership and work cooperatively with water associations, local government, and local interests, including

tribes. Should tribes choose to supply water to the EWA, transactions will comply with procedures contained in the Department of Interior Department Manual Part 512, Chapter 2. These guidelines protect tribal resources and require approval of the Secretary of Interior before sale of land, natural resources, water, or other assets. Federally reserved water rights held in trust for tribes by the United States are ITAs that are restricted from being separated from tribes and individual Indians without the approval of the Secretary of the Interior.

20.1 Affected Environment/Existing Conditions

The EWA Study area comprises the Upstream from the Delta Region and the Export Service Area. Because there are no Indian trust lands located in the Delta, and no actions potentially affecting ITAs are planned in the Delta, this section eliminates this geographic area from further ITA impact analysis.

Areas for groundwater purchase and additional groundwater storage are limited to areas previously used for groundwater storage; therefore, any new sale of groundwater for EWA purposes can only occur from existing groundwater storage areas. Because these actions would not affect ITAs, this section eliminates such options from further analysis.

Exercising source shifting to protect against a low point problem in San Luis Reservoir involves increased use of water from Castaic Lake, Lake Perris, Lake Mathews, Anderson Reservoir, and Diamond Valley Lake. There is no direct overlap between these reservoirs and Indian land. The Soboba Reservation lies less than ten miles northeast of Diamond Valley (Welch 2003). This section will not include detailed effects analysis for source shifting because Indian trust land does not overlap reservoirs that are subject to source shifting and the nearest reservoir is ten miles north east of Diamond Valley Lake.

Acquiring EWA assets through increased use of stored reservoir water involves reservoirs on the Middle Fork of the Upper American River (French Meadows and Hell Hole), North Yuba River (New Bullards Bar), and South Fork of the Feather River (Little Grass Valley and Sly Creek). Based on GIS data, the nearest trust land is 9.2 miles away from the reservoirs in question (Welch 2003). It is presumed there are no off-reservation, federally-reserved hunting, fishing, or gathering rights near reservoirs proposed for stored reservoir water transfer[1].

Crop idling could produce fugitive dust that may affect adjacent land uses. Rainfall and rice production practices in upstream areas, and mitigation measures outlined in Section 8.2.7 would reduce potential effects to a less than significant level.

[1] Project proponents need to acquire enabling legislation that establishes Indian trust land and any off-reservation federally reserved rights.

Groundwater substitution could result in increased depth to groundwater in neighboring vicinities and/or increasing costs of groundwater pumping. This action could interfere with federally reserved water rights.

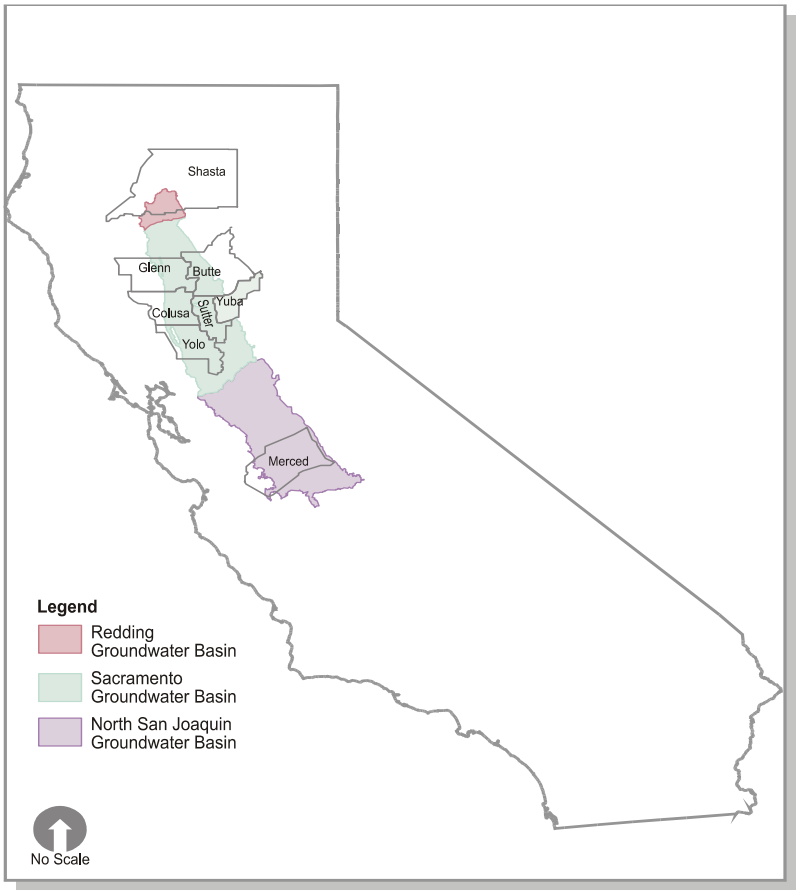

Figure 20-1
Indian Trust Assets Area of Analysis

20.1.1 Area of Analysis

Groundwater substitution is the only water acquisition option that could potentially affect ITAs. EWA agencies are proposing groundwater substitution in the Upstream from the Delta Region along the Sacramento, Feather, Yuba , and Merced Rivers (Figure 20-1). Discussion of ITAs proceeds from north to south along these river systems.

20.1.1.1 Upstream from the Delta Region

20.1.1.1.1 Sacramento River

The northernmost indigenous California people in the EWA project area were the Achowami, Atsugewi, Ajumawi, Wintun, Pit River, and the Yana (San Diego State University 2002). Descendants of these tribes live on the Big Bend, Burney Tract, Montgomery Creek, Redding, and Roaring Creek Rancherias in Shasta County. Shasta County also has 15 PDAs.

Maidu and Wintun people inhabited the downstream Colusa Basin section of the Sacramento River (CDM 1995; Glenn Colusa Irrigation District, California Department of Fish & Game, U.S. Bureau of Reclamation, U.S. Army Corps of Engineers 1998). The Wintun Tribe comprises three divisions: Patwin, Nomlaki, and Wintu. Present-day descendants of the Wintun live on the Colusa (Cachil Dehe) and Cortina Rancherias in Colusa County and Rumsey Rancheria in Yolo County. Wintun-Wailaki descendants in Glenn County live on the Grindstone Creek Rancheria. The Paskenta Band of Nomlaki Indians has a large tract of trust land in Glenn County, just northwest of Orland, near I-5. Colusa County has one PDA; there are no PDAs in Glenn and Yolo Counties.

20.1.1.1.2 Feather River

Evidence indicates that the Feather River region was inhabited by the Wintun and Maidu people for thousands of years. The Konkow, the northwestern branch of the Maidu nation, inhabited portions of the Central Valley and western slopes of the Sierra Nevada to the north and northeast of Sutter Buttes. The Konkow were bordered on the west by the Nomlaki (Wintun) and on the north by the Yana and Northeastern Maidu. The southernmost group of the Yana was the Yahi (City of Oroville 1995; Butte County 1998). The southernmost Maidu called themselves the Nisenan people, and occupied the drainages of the Yuba, Bear, and American Rivers, and the lower drainages of the Feather River (Sutter County 2001).

Major political Nisenan sites were along the mouths of the Feather, American, and Yuba Rivers. Abundant game, waterfowl, fish, and plant resources supported the entire region (Wilson and Towne 1978).

Descendants of the Maidu live on the Greenville Rancheria in Plumas County and on the Mooretown, Berry Creek, and Enterprise Rancherias in Butte County. The Mechoopda Indian Tribe of the Chico Rancheria (a federally-recognized Tribe) recently acquired 50 acres in fee status in Butte County. Fee land by definition is not held in trust by the United States.

Two PDAs exist in Butte County. Sutter County has no rancherias, reservations, or PDAs.

20.1.1.1.3 Yuba River

Native Americans indigenous to Yuba County are the Maidu. Southern Maidu occupied the Bullards Bar area. Valley Nisenan villages were generally located along watercourses (Yuba County 1994). Yuba County has no rancherias, reservations or PDAs.

20.1.1.1.4 Merced

Inhabited largely by the Yokuts Indian group, the San Joaquin Valley contained approximately 50 different Yokuts tribes. Tribes typically occupied areas along small creeks and streams where villagers could weave lodges out of the profusely growing tule. The Yokuts were nearly extinct by the 1800s due to diseases brought by missionaries and miners (Merced County 2001). Merced County contains no rancherias, reservations, or PDAs.

20.2 Environmental Consequences/Environmental Impacts

20.2.1 Assessment Methods

Under each alternative, the EWA Project Agencies would negotiate contracts with willing sellers based on a number of factors, including price, water availability, and location. These factors would change from year-to-year; therefore, the EWA Project Agencies may choose to vary their acquisition strategy in each year. For maximum

flexibility, this analysis includes many potential transfers when the EWA Project Agencies would likely not need all transfers in a given year. Chapter 2 defines the transfers that are included in this analysis.

Potential effects on ITAs stem from actions or activities that would affect Indian trust lands and federally reserved hunting, fishing, gathering, water, or other rights. Groundwater substitution could potentially affect ITAs. The first step of the impact analysis was to identify likely locations for EWA groundwater substitution transfers and their relationship to ITAs through the following process:

1) The Bureau of Indian Affairs 2000 Indian Trust Lands map was used to identify and eliminate tribal trust lands in the foothills of the Coast Range and Sierra Nevada, as groundwater transfers will not take place in these locations.
2) Indian trust lands located outside of groundwater basins (in areas of consolidated rock) and far from any EWA pumping in the Central Valley were eliminated (such as the Cortina and Table Mountain Rancherias). EWA groundwater substitution transfers would not occur in these areas.
3) Potentially affected ITAs in unconsolidated deposits of sands and gravels with major rivers and streams that act as recharge sources in the Central Valley include those associated with the:

    a. Redding Rancheria
    b. Colusa (Cachil Dehe) Rancheria
    c. Paskenta Band of Nomlaki Indians

4) Consistent and careful monitoring would ensure that groundwater transfers do not deplete riverflows.

If EWA agencies identify potential impacts to ITAs, tribal consultation will then precede any formal EWA groundwater transfer in the vicinity of the three identified tribes. Government–to-government consultation shall take place to determine interests, concerns, effects, and appropriate mitigation measures. (Refer to Figure 20-1.) Consultation may involve the EWA agencies, the Bureau of Indian Affairs, the Regional Solicitor's Office, and the California Department of Water Resources (DWR).

20.2.2 Significance Criteria

An effect is considered potentially significant if implementation of an EWA action would adversely affect ITAs. Direct effects are those that result from EWA acquisitions via groundwater substitution.

This analysis determines that groundwater substitution operations would have significant effects if the action:

- Interferes with the exercise of a federally reserved water right;

- Degraded water quality where there is a federally reserved water right;
- Adversely affects the health of the tribe by decreasing water supplies;
- Interferes with the use, occupancy, or character of Indian trust lands by decreasing groundwater tables;
- Adversely affects fish and wildlife where there is a federally reserved hunting, gathering, or fishing right.

20.2.3 Environmental Measures Incorporated into the Project Description

Consistent with the CALFED ROD and the Department of Interior Departmental Manual Part 512 Chapter 2, EWA agencies have adopted the following environmental measures into the project description to reduce the EWA's potential effects on ITAs.

1) If there is a potential effect to ITAs identified by the EWA agencies, then consultation will be initiated by the EWA agencies with the affected tribes in the groundwater sub-basin as defined in Bulletin 118 before groundwater substitution transfers are finalized and signed. The purpose of the tribal consultation will be to further identify the nature of the effect and to identify appropriate mitigation measures.

2) EWA agencies will discuss appropriate avoidance and/or mitigation strategies on a government-to-government basis. The tribal consultation process will take place with the affected federally-recognized Indian tribes and EWA agencies. Separate mitigation measures may be required for different types of trust assets, including federally reserved water, land, minerals, hunting, fishing, and gathering rights. Mitigation measures would ensure compliance with thresholds of significance documented within this EIS/EIR. Mitigation measures are found in Sections 4.2.8 (Surface Water Supply and Water Management), 7.2.7 (Geology and Soils), 8.2.7 (Air Quality), and 16.3.9 (Power Production).

20.2.4 Environmental Consequences/Environmental Impacts of the No Action/No Project Alternative

In the No Action/No Project Alternative, ITAs would remain protected and intact. Water transfers from existing groundwater storage basins would continue to respect the integrity of federally protected lands, minerals, hunting and fishing rights, water rights, and in-stream flows associated with a reservation, rancheria, or PDA. The No Action/No Project Alternative would not affect water usage or availability. Land use, occupancy, and character of Indian trust lands would remain unaffected. The No Action/No Project Alternative, therefore, reflects the same conditions as the Affected Environment. The No Action/No Project Alternative would have no effect on ITAs.

Figure 20-2

The NEPA basis of comparison is the Future Conditions Without the Project. As described in the above paragraph, the Affected Environment and the Future Conditions Without the Project are the same; therefore, they are collectively referred to as the Baseline Condition in the following sections.

20.2.5 Environmental Consequences/Environmental Impacts of the Flexible Purchase Alternative

The Flexible Purchase Alternative allows transfers of up to 600,000 acre-feet and does not specify transfer limits in the Upstream from the Delta Region or the Export Service Area. Transfers that take place in the Upstream from the Delta Region would be between 50,000 and 600,000 acre-feet, limited by hydrologic year and conveyance capacity through the Delta. Although all potential transfers would not occur in one year, this section discusses potential impacts of maximizing groundwater substitution, although EWA agencies have a variety of available acquisition options that they may choose to vary according to hydrologic conditions and need. Because groundwater substitution would not occur in the Export Service Area, this EWA action would not affect the Export Service Area. The following impact analysis concentrates on the Upstream from the Delta Region.

20.2.5.1 Upstream from the Delta Region

The following impact analysis and discussion is not divided along rivers. The potential effects on ITAs due to groundwater substitution would not differ by county or river, except that the EWA agencies have not proposed groundwater substitution along the American River. Therefore, the effects of groundwater substitution on the remaining rivers are evaluated together.

20.2.5.1.1 Sacramento, Feather, Yuba, and Merced Rivers

EWA acquisition of water from Sacramento River Agencies, Feather River Agencies, Yuba County Water Agency, and Merced Irrigation District via groundwater substitution would decrease groundwater levels. Landowners and tribes in the vicinity of a groundwater substitution transfer could experience drawdown in wells relative to the Baseline Condition, which could increase costs of bringing the water to the surface or potentially dry out wells. Section 6.2.7, Groundwater Mitigation Measures, contains specifications for monitoring and mitigation plans that reduce potential third party effects. Water acquisitions shall require notification of the EWA agencies, and if potential effects to ITAs are identified, then consultation by EWA agencies with the affected federally-recognized Indian tribe will commence before the water acquisition is finalized in order for the EWA agencies to fully execute their Federal Indian trust responsibilities. The EWA agencies in consultation with affected tribes will identify tribal concerns, issues, tribal regulations, and recommendations that could further minimize effects to ITAs.

Multi-year contracts for sale of water to EWA agencies are contingent on the abovementioned groundwater mitigation measures. Transfers should:

- not exceed significance criteria found in Groundwater Section 6.2.2;
- assure that use of extraction wells minimizes risk to surface and groundwater quality;
- incorporate an adequate monitoring program; and
- proceed only after appropriate tribal consultation has been completed, if federally-recognized ITAs are potentially affected.

All groundwater mitigation measures must be implemented before the EWA agencies authorize a second year of groundwater acquisitions.

20.2.6 Environmental Consequences/Environmental Impacts of the Fixed Purchase Alternative

The Fixed Purchase Alternative specifies purchases of 35,000 acre-feet in the Upstream from the Delta Region and 150,000 acre-feet in the Export Service Area. While the amounts in each region are fixed, the acquisition types and sources could vary. To allow the EWA Project Agencies maximum flexibility when negotiating purchases with willing sellers, this section documents the effects of maximum groundwater substitution though the EWA agencies have various acquisition options.

20.2.6.1 Upstream from the Delta Region

The effects of groundwater transfers for the Flexible Purchase Alternative, which are decreased groundwater levels and increased groundwater pumping costs, are similar for the Fixed Purchase Alternative. However, groundwater transfers under the Fixed Purchase Alternative in the Upstream from the Delta Region are substantially less than those under the Flexible Alternative because purchases are limited to 35,000 acre-feet.

20.2.6.1.1 Sacramento, Feather, Yuba, and Merced Rivers

EWA acquisition of water from Sacramento River Agencies, Feather River Agencies, Yuba County Water Agency, and Merced Irrigation District via groundwater substitution would decrease groundwater levels. Landowners and tribes in the vicinity of a groundwater substitution transfer could experience drawdown in wells relative to the Baseline Condition, which could increase the costs of bringing the water to the surface or potentially dry out wells. Chapter 6, Groundwater Resources, contains specifications for monitoring and mitigation plans that reduce potential third party effects. Water acquisitions shall require notification of the EWA agencies, and if potential effects to ITAs are identified, then consultation with the affected federally-recognized Indian tribe by EWA agencies will commence before the water acquisition is finalized in order for the EWA agencies to fully execute their Federal Indian trust responsibilities.

Multi-year contracts for sale of water to EWA agencies are contingent on the abovementioned groundwater mitigation measures. Transfers should:

- not exceed significance criteria found in Groundwater Section 6.2.2;
- assure that use of extraction wells minimizes risk to surface and groundwater quality;
- incorporate an adequate monitoring program; and
- proceed only after appropriate tribal consultation has been completed, if federally-recognized ITAs are potentially affected.

All groundwater mitigation measures must be implemented before the EWA agencies would authorize a second year of groundwater acquisitions.

20.2.7 Comparative Analysis of Alternatives

This section analyzes the effects of maximum groundwater substitution transfers that could occur in 1 year for the Fixed and Flexible Purchase Alternatives. This "worst case" scenario approach ensures that all effects of transfers are identified and provides the EWA Project Agencies contract negotiation flexibility when choosing between acquisition options. EWA agencies, however, would not actually purchase all this water in the same year. This section provides information about how EWA agencies would more likely operate in different hydrologic years.

During No Project conditions, as well as with the project, federally reserved lands, minerals, hunting and fishing rights, water rights, and in-stream flows associated with a reservation, rancheria, or PDA remain protected. The No Action/No Project Alternative would not affect water usage or availability. Land use, occupancy, and the character of Indian trust lands would remain unaffected regardless of hydrologic conditions.

20.2.7.1 Upstream from the Delta Region

In the Upstream from the Delta Region, the Fixed Purchase Alternative would be limited to a maximum acquisition of 35,000 acre-feet from all sources of water. In most years, this amount could be obtained from surface water storage from non-Project reservoirs. The Fixed Purchase Alternative would not likely involve groundwater substitution transfers; therefore, it would not likely affect ITAs.

The Flexible Purchase Alternative could involve the purchase of up to 600,000 acre-feet of water from multiple sources in the Upstream from the Delta Region. EWA agencies would prefer to purchase water from upstream sources because the water is generally less expensive. The amount that could be purchased would be limited by the available capacity of the Delta export pumps to move the water to export areas south of the Delta. During wet years, available pump capacity may be limited to as little as 50,000 to 60,000 acre-feet of EWA water because the pumps primarily would be used to export State and Federal Project water to Export Service Area users. During dry years, when less Project water would be available for pumping (and therefore the

pumps would have greater available capacity), the EWA Project Agencies could acquire up to 600,000 acre-feet of water in the Upstream from the Delta Region.

The potential for effects on ITAs during wet years for the Flexible Purchase Alternative would be very similar to the Fixed Purchase Alternative. That is, during wet years, acquisitions would most likely be from stored water sources, and the EWA agencies would not purchase water through groundwater substitution. As rainfall amounts for areas north of the Delta decrease, reflecting dry year conditions, the greater capacity of the export pumps to move EWA assets could result in a greater reliance on groundwater substitution transfers for the additional EWA acquisitions. If the EWA Project Agencies were to make a 600,000 acre-foot acquisition in the Upstream from the Delta Region, they would need to utilize most available sources, which would include stored reservoir water, groundwater substitution, groundwater purchase, and crop idling.

Although groundwater mitigation measures described in Section 6.2.7.2 would be employed to minimize potential impacts, the greater reliance on groundwater during dry years could result in the Flexible Purchase Alternative having a greater potential for effects on ITAs than the Fixed Purchase Alternative. The greatest potential for effects would be if there were several dry (drought) years in a row, a time period when other water users upstream of the Delta would also be relying on groundwater resources as a major portion of their water supply.

20.2.7.2 Export Service Area

The EWA agencies would acquire assets in the Export Service Area from stored groundwater and crop idling sources. Stored groundwater would be acquired from agencies that have previously stored water in the ground (e.g., Kern Water Bank, Santa Clara Valley Water District); therefore, there would be no effects on ITAs.

A summary of the effects of the Fixed Purchase and Flexible Purchase Alternatives are listed in Table 20-1.

Table 20-1
Comparison of Effects on Indian Trust Asset by Fixed vs. Flexible Purchase Alternatives

Region	*Asset Acquisition or Management*	*Result*	*Effects*	*Flexible Alternative Change*	*Fixed Alternative Change*	*Significance of Flexible Alternative*	*Significance of Fixed Alternative*
Sacramento, Feather, Yuba, and Merced Rivers	Groundwater substitution	Decrease ground-water levels beyond the Baseline Condition	Could increase pumping costs or dry out wells on property owned by tribes in vicinity of groundwater substitution transfer	Total 330 TAF groundwater substitution transfer in upstream region; no groundwater substitution in Export Service Area	Total 35 TAF groundwater substitution transfer in upstream region; no groundwater substitution in Export Service Area	Potentially affected trust lands warrant government-to-government consultation	Potentially affected trust lands warrant government-to-government consultation

20.2.8 Mitigation Measures

Groundwater substitution could result in increased depth to groundwater in neighboring vicinities and/or increasing costs of groundwater pumping. This action could interfere with federally reserved water rights. Groundwater transfers occurring within 1-2 miles of ITAs associated with the Redding Rancheria, Colusa Rancheria, or Paskenta Band of Nomlaki Indians would undergo consultation with affected federally recognized tribal governments, EWA agencies, the Bureau of Indian Affairs, the Office of the Solicitor, and the Office of American Indian Trust.

1) Consultation could identify any of the following mitigation measures as appropriate for reducing effects to a less than significant level:

   - more frequent groundwater monitoring
   - more detailed pre-purchase groundwater evaluation
   - estimates of potential interference with Indian wells
   - discontinuation of EWA groundwater pumping if groundwater levels are drawn down to a level of concern. (Refer to Section 6.2.7.2).

2) Mitigation measures necessary to reduce effects to a less than significant level will be developed in consultation with the affected federally recognized tribe(s), before implementation. Other mitigation measures will be used as determined appropriate through tribal consultation.

20.2.9 Potentially Significant and Unavoidable Impacts

There are no expected significant and unavoidable impacts to ITAs. The United States will consult with appropriate tribes to identify possible effects and avoid or mitigate adverse effects.

20.2.10 Cumulative Effects

Other water acquisition programs considered in the cumulative effects analysis include the Sacramento Valley Water Management Agreement, Dry Year Purchase Program, Drought Risk Reduction Investment Program (DRRIP), Central Valley Project Improvement Act (CVPIA) Water Acquisition Program (WAP), and Environmental Water Program (EWP). This ITA cumulative analysis focuses only on those programs that potentially pose incrementally detrimental effects through groundwater substitution in all areas of the State.

Groundwater substitution is a component of all the water acquisition programs. During wet years, the only groundwater substitution programs are EWA, EWP, and the CVPIA WAP. Recharge in wet years would decrease effects; however, they are

still considered potentially significant. Effects described in Chapter 6, Groundwater Resources, are potentially cumulatively significant in both wet and dry years without appropriate mitigation. Water transfers concerning the abovementioned water acquisition programs will be facilitated through CALFED's Water Transfer Program.

It is reasonable to assume that other groundwater usage programs could evolve in the foreseeable future. As discussed in Chapter 6, Groundwater Resources, all are required to have monitoring and mitigation plans that prevent third party effects, similar to those that apply to EWA actions. Careful monitoring and management is necessary to mitigate any potential effects to a less than significant level. Additionally, all EWA groundwater substitution acquisitions in the vicinity of an ITA require notification of the United States before such acquisitions are finalized in order for the United States to fully execute its Indian Trust responsibilities. After deliberation by subject matter experts and appropriate tribal consultation, mitigation would reduce effects to a less-than-significant level.

Chapter 21
Growth Inducing Impacts

21.1 Introduction

The California Environmental Quality Act (CEQA) Guidelines, in Section 15126.2(d), require an environmental document to:

> *"Discuss the ways in which the proposed project could foster economic or population growth, or the construction of additional housing, either directly or indirectly, in the surrounding environment. Included in this are projects which would remove obstacles to population growth..."*

The following brief discussion presents general factors that could result in growth inducing impacts. Also included thereafter is an analysis of the relationship between growth and the increased water supply reliability provided by the Environmental Water Account (EWA). This chapter provides an overall evaluation of the potential for regional growth inducement resulting from implementation of the EWA.

21.2 Growth Inducing Factors

In general, an action would be considered growth inducing if it caused or contributed to economic or population growth. Growth-inducing actions result in more economic or population growth than would have occurred otherwise from other factors. Thus, a growth-inducing action would promote or encourage growth beyond that which could be attributed to other factors known to have a significant relationship to economic or population growth.

Although a project may have growth inducing potential, it may not result in growth. Each municipality or county controls growth at the local level through land use policies in each jurisdiction. Decision-makers alone are able to transform growth-inducing potential or pressure, created by economic or social conditions, into actual growth (CALFED 2000a).

21.3 Current Growth

State and regional service and planning agencies, such as the California Department of Finance, Southern California Association of Governments, Bay Area Association of Governments, Sacramento Area Council of Governments, Council of Fresno County Governments, and the Butte County Association of Governments have prepared extensive studies and reports forecasting California's economy, population, and resources. These studies and reports have been approved and adopted by the respective agencies, in cooperation with local jurisdictions, as the most likely scenarios for growth in this region.

The primary objectives of these demographic projections, and the planning policies on which they are based, are to evaluate the potential social, economic, environmental,

and fiscal impacts that may result from this level of projected growth and to identify mitigation required to reduce or eliminate these impacts (MWD and BLM 2001).

These projections take into account the predicted adverse impacts of growth. In other words, state and regional planning agencies project growth to occur despite possible shortfalls in water supply, heavy traffic, and other factors that are sometimes assumed to be growth limiting. As it relates to this document, growth will occur with or without the EWA or CALFED programs. Table 21-1 indicates the South of Delta counties population forecast for year 2020, in five-year increments, determined by the California Department of Finance.

Table 21-1
South of the Delta Population Forecast

County	*2000*	*2005*	*2010*	*2015*	*2020*
Alameda	1,466,900	1,580,200	1,671,200	1,735,800	1,811,800
Calaveras	41,000	47,800	53,400	57,900	62,200
Contra Costa	963,000	1,021,400	1,071,400	1,108,100	1,152,900
Fresno	816,400	893,300	970,900	1,043,100	1,134,600
Imperial	149,000	182,500	217,500	252,000	294,200
Kern	678,500	771,300	871,600	972,700	1,088,600
Kings	134,500	149,600	165,300	180,800	198,700
Los Angeles	9,716,000	10,169,100	10,605,200	10,983,900	11,584,800
Madera	127,700	152,600	178,900	203,000	229,200
Mariposa	17,300	19,600	21,500	23,000	24,300
Merced	214,400	239,900	266,700	292,400	322,700
Monterey	408,700	450,300	493,100	535,700	590,700
Orange	2,893,100	3,099,700	3,266,700	3,384,300	3,541,700
Riverside	1,577,700	1,864,700	2,159,700	2,459,600	2,817,600
San Benito	54,500	63,600	72,000	79,100	86,800

21.4 The CALFED PEIS/EIR and Water Supply Reliability

The CALFED Bay-Delta Preferred Program Alternative is expected to result in an improvement in water supply reliability and availability for beneficial use in the Upstream from the Delta Region, Delta Region, and Export Service Area, within State Water Project (SWP) and Central Valley Project (CVP) Service Areas. Discussions of

whether additional water supplies and/or improvements in water supply reliability could induce growth often result in differences of opinion; therefore, this topic is considered an area of controversy as used in National Environmental Policy Act (NEPA) and CEQA. Because this issue cannot be predicted with certainty, the programmatic level of analysis in the CALFED PEIS/EIR made the assumption that any increase in water supplies and/or improvements in water supply reliability associated with the CALFED program would stimulate growth, as discussed in Section 5.1 of the CALFED PEIS. This assumption was made to disclose the environmental consequences associated with growth in the event that CALFED program actions ultimately lead to this type of change. Also considered in the formation of this assumption was the knowledge that the CALFED program is a long-term program, expected to continue 30 or more years (CALFED 2000a).

21.5 The EWA and Water Supply Reliability

The EWA's purpose within the CALFED program is to provide protection to the targeted at-risk fish species of the Bay-Delta estuary through environmentally beneficial changes in SWP/CVP operations. The EWA program includes commitments that improve the reliability of the water supply available from the Bay-Delta system (CALFED 2000b). In this way the EWA meets the two-fold purpose of the CALFED program: to "restore ecological health and improve water management for beneficial uses of the Bay-Delta system (from the CALFED program statement of purpose) (CALFED 2000b)."

It has not been determined whether an EWA should be a long-term program within the overall CALFED program. As described in Chapter 1 of this document, the CALFED Record of Decision (CALFFED ROD) identified an EWA during the first 4-years of the CALFED program. According to the EWA Operating Principles Agreement, the five EWA agencies are to review the effectiveness of the EWA after 4 years and decide whether to continue an EWA as implemented, address changes to the program, or seek a more permanent solution to water reliability issues. If the EWA agencies decide that an EWA should continue as described in this EIS/EIR, this document covers and analyzes the environmental effects of the EWA until the end of Stage 1 (until 2007).

The EWA Fixed and Flexible purchase alternatives would both help to ensure short-term increases in the reliability of water supply for all SWP and CVP users to the degree that they provide the Endangered Species Act (ESA) commitments to the SWP and CVP and do not allow jeopardy conditions or uncompensated Delta export pumping reductions to occur. However, the exact contribution of either alternative to water supply reliability is hard to estimate. Absent an EWA program, export reductions at the SWP and CVP pumps could occur when the U.S. Fish and Wildlife Service (USFWS), National Marine Fisheries Service (NOAA Fisheries), and California Department of Fish and Game (CDFG) determined that levels of fish take at the Delta export pumps had reached levels of concern as specified in the Biological Opinions or when the Projects voluntarily reduced pumping to avoid a potential jeopardy determination under the Endangered Species Act (ESA). Without the cooperative

forum provided by an EWA, the Bureau of Reclamation (Reclamation) and California Department of Water Resources (DWR) would resist implementing voluntary uncompensated pumping reductions and disagreements with USFWS, NOAA Fisheries, and CDFG could ultimately result in a solution that imposed a strict, prescriptive interpretation of the ESA. Mandatory reductions would then result in unexpected delivery interruptions to CVP and SWP water supply and reduce total water deliveries to SWP and CVP users. The Fixed or Flexible EWA alternatives would directly or indirectly contribute to water supply reliability through avoidance of the possible mandated pumping reductions or curtailments and their potential impacts to Project water supply. Voluntary pumping reductions under an operable EWA program do not affect water supply because all voluntary pumping reductions are replaced at a later time with an identical amount of EWA assets.

Because of the dynamic nature of fish populations and biology, the annual variation in California's hydrology, and the short time frame analyzed by this document (through 2007), it is impossible to predict the timing and magnitude (in lost water deliveries) of any uncompensated pumping reductions that might occur under baseline conditions or future No Project conditions. There is no model that can predict when pumping reductions would be required to prevent jeopardy to at-risk fish species in the Delta. Such a model would have to identify the timing, magnitude, and duration of these pumping reductions to identify the amount of water foregone by the Projects. The model would also have to simulate the allocation processes employed by both the CVP and SWP to determine the loss in deliveries in the affected year. Additionally, the model would have to predict and simulate how the Projects would employ other operational tools and flexibility to partially compensate for the lost pumping opportunities. Because no model exists or can realistically be developed, quantifying the actual amount of increased water supply and reliability under the Fixed or Flexible Purchase Alternatives is not possible at the present time.

Assuming mandatory pumping reductions occurred under the baseline condition, the Flexible Purchase Alternative would provide more protection and water supply reliability to the SWP and CVP than the Fixed Purchase Alternative if the larger quantity of EWA assets it entails were required to maintain ESA commitments and avoid uncompensated pumping reductions. If the Fixed purchase alternative allows the EWA Management Agencies sufficient EWA assets to provide the Projects with ESA commitments, then both the Fixed and Flexible purchase alternatives would result in the same net increase in water supply reliability through avoidance of uncompensated pumping reductions. The increase in amount of SWP and CVP water supply reliability would be measured by the amount of water saved and the frequency of such savings through avoidance of uncompensated pumping reductions mandated through regulatory or other means without the ESA commitments that an operable EWA provides to the Projects. The No Project alternative would not increase water supply reliability of the SWP and CVP. The No Project alternative could actually result in decreased water supply reliability if conditions occur that increase the conflicting pressures between CVP and SWP water deliveries and protection of targeted at-risk fish populations in the Delta through Project pumping reductions.

An EWA's potential to provide an additional amount of water to the SWP and CVP above the baseline amount, because ESA commitments provide that no uncompensated pumping reductions will occur, could indirectly relate to growth. Water supply could potentially remove an obstacle to growth, accommodate growth, or induce growth depending on site-specific factors individual to every local government jurisdiction and proposed development throughout the State. One factor of importance to consider is that EWA-related water supply reliability, in the face of mandated cuts, would benefit both urban and agricultural water contractors of the CVP and SWP. Therefore, not all of an EWA-related increase in water supply reliability would potentially accommodate, induce, or remove an obstacle to growth, but only that portion that provides reliability to urban service areas. Another major factor is that almost all local urban water agencies in the State rely on more than one source of water to provide a dependable supply to customers.

Water supply reliability alone is not the determinative factor causing, inducing, or accommodating growth in any region of California. Water supply reliability for urban population growth and development is taken into account to varying degrees by local planning agencies in General Plans and Water Supply Master Plans. The sophistication and complexity of this process has increased in the past decade as better predictive models and data have surfaced. Public attention has also focused on the recognition that water supply is one of the key factors to consider when planning new developments. Community planners, developers, industries, and others seeking to implement or realize urban growth in California are required to demonstrate a reliable water supply. Two bills enacted in 2001 by the California Legislature, SB 221 (Kuehl) and SB 610 (Costa), require cities and counties to look very closely at long-term water supply reliability when approving land development projects consisting of more than 500 housing units. SB 221 defines "sufficient water supply" as the "total water supplies available during normal, single-dry, and multiple-dry years within a 20-year projection that will meet the projected demand." These recent laws reinforce and strengthen the need for proper water supply planning at local government levels. They also emphasize the need for accurate and careful information regarding reliable water supplies.

In May 2003 DWR published the first in a biannual series of State Water Project Reliability Reports to provide information on the "ability of the SWP to deliver water under existing and future development." The analysis and report assumed operation of an EWA similar to that in the CALFED ROD even though the EWA is currently short-term. This inclusion was only to simulate potential SWP and EWA operations and coordination and did not materially affect the final SWP water supply reliability analysis contained in the report because only voluntary pumping reductions were simulated, each of which was compensated using simulated EWA assets. The mandated pumping reductions that could occur absent an EWA, which would materially alter SWP reliability, were not included in the CALSIM II modeling conducted for the Reliability Report due to the aforementioned difficulty of generating and simulating them with a current model. Because of its inclusion in the Reliability Report, however, an EWA may be considered a long-term program by

some local planning agencies and they may rely on the Reliability Report without considering the potential impacts of uncompensated pumping reductions if an operable long-term EWA is not approved by all EWA agencies and ESA commitments are not granted to the CVP and SWP. Assuming that uncompensated pumping reductions would occur in some years under baseline conditions, there could be less water delivered by the SWP than now stated in the Reliability Report, but that amount is unknown. The Reliability Report cautions that not all model assumptions about the future operation of the SWP are accurate including those involving future hydrology, regulatory constraints, biology, and demographic patterns. Despite these cautions, some local agencies might rely on the inclusion of an operable EWA in the Reliability Report. Because the report contains no analysis concerning the quantity or frequency of uncompensated pumping reductions that could occur if ESA commitments were not provided through an operable EWA, an EWA program could be considered to affect local planning agency decisions on growth.

Many urban water agencies rely on water from multiple sources including groundwater, local storage projects, imported surface water, water from long-term or temporary transfers, reclamation programs, and conservation programs. These multiple sources create a "portfolio" of water management options and strategies. Taking their specific water sources into account, each local water purveyor individually analyzes and releases information on its own water supply reliability for use by local planning agencies. Because local agencies may incorporate the SWP Reliability Report in assessing the availability of water supplies for growth, the Reliability Report may be used by those agencies as one factor in assessing the reliability of water supplies when approving developments and growth. In this sense, the concept of an EWA and its benefits to reliability may be one of the pieces of information that a local planning agency or developer takes into account when considering a project and may remove an obstacle to growth. The Reliability Report, however, is not the only information, nor is it the final determination of water supply reliability for any area because the local water "portfolio" must be examined along with the local water supplier's own reliability data, which usually include more than strict annual reliance on SWP allocations.

It is unknown whether any growth would be denied by local agencies in the absence of the EWA, and it is too speculative to attempt such a determination in this document. There are no known current development projects awaiting EWA approval for final authorization at the local level. All decisions on development and growth are ultimately made at the responsible local agency level using a long-term planning horizon.

Growth and development are not inherently deleterious. Growth can be beneficial, benign, or cause adverse environmental impacts. There is no way to predict the size and location of any growth that might occur due to potential increased supply reliability of the SWP and CVP because of a short-term EWA. Each local government must evaluate each development plan within its purview, assess its environmental impacts, and ultimately approve or disapprove any growth. At this level of local specificity, environmental impacts would be identified to the public. It is the

responsibility of local agencies to choose whether to mitigate for any negative impacts of growth they have approved within their jurisdiction. There is no way that the EWA agencies can estimate the magnitude of growth, its location, or the level of significance of any direct, indirect, or cumulative impacts that may be caused by any growth based on the limited role that a short-term (through 2007) Fixed or Flexible EWA alternative may or may not play in local water supply assessments and local-decision making processes.

Chapter 22
Cumulative Effects

Cumulative effects analyses are an important component of the environmental documentation and approval process and are required by both the National Environmental Policy Act (NEPA) and the California Environmental Quality Act (CEQA). Both CEQA and NEPA require the cumulative effects analysis to include future actions and projects that can be reasonably predicted to occur within the term of the proposed project. The cumulative effects analyses in this Environmental Impact Statement/Environmental Impact Report (EIS/EIR) evaluate the combined effects of the Environmental Water Account (EWA) and other water acquisition programs that could engage in water transfers similar to those of the EWA. The cumulative effects analyses also consider projects proposing physical changes to storage, export, or conveyance facilities in the Delta. The timeframe of the cumulative analyses extends through 2007, which coincides with the completion of Stage 1 of the CALFED Bay-Delta Program implementation.

Sequentially, this chapter first introduces the general methodology for evaluating cumulative effects to resources, then describes the additional future programs and projects considered in the cumulative analysis. The cumulative condition is then summarized as a whole in regards to water acquisition programs and Delta improvement projects. Each resource chapter includes a cumulative effects assessment that discusses the cumulative effects of the particular resource. Section 22.4 briefly summarizes these resource cumulative analyses.

22.1 Cumulative Effects Methodology

The major cumulative actions considered in the analysis fall into two categories:

- Water acquisition programs; and
- Water storage, conveyance, or export facility improvement projects, mainly concentrated in the Delta.

The sections below discuss the cumulative assessment methods for each category. Each resource chapter may discuss additional programs in the cumulative analysis section that pertain specifically to the resource. This chapter does not discuss these additional programs. In general, the cumulative effect analyses rely upon hydrologic modeling and other quantitative and qualitative assessments to determine the potential combined effect of the EWA and other related programs over the projected timeframe.

22.1.1 Other Water Acquisition Programs

The evaluation of the cumulative effects of all water acquisition programs considered addresses three primary issues:

1. *The effects of transferring the total quantity of water through the Delta that all programs may purchase.* The available capacity of the Central Valley Project (CVP) and State Water Project (SWP) Delta pumps to export water and the amount of water available for purchase would limit the total quantity of water for transfer.

   In most instances the cumulative analyses are similar to the Flexible Purchase Alternative analyses. The Flexible Purchase Alternative analyses examine a "worst–case scenario" that maximizes the utilization of available export capacity of Delta facilities that limits transfers for all the acquisition programs. As a consequence, implementation of one or more of the programs in conjunction with the EWA would alter the beneficiary of the transferred water, but the total supply of water from upstream sources would not be any greater than that analyzed for the Flexible Purchase Alternative.

2. *The interrelationship between the water purchase programs*. Some of the programs have higher priority for conveyance and/or pumping capacity than others. According to the 2003 Protocols for the Operation of the EWA, the following is the priority for pumping at SWP and CVP pumps (from highest to lowest priority):

   SWP:
   - SWP Pumping
   - Water transfers for SWP contractors
   - Joint Point of Diversion (JPOD) use for specific CVP contractors
   - Wheeling for CVP and EWA (split 50-50 between CVP and EWA/Refuge Level 4 purchases)[1]
   - Water transfers for others

   CVP:
   - CVP Pumping
   - Refuge Level 4
   - Cross Valley Canal
   - EWA
   - Water transfers for others

   Because of the relaxation of the Section 10 constraint of the River and Harbors Act, EWA has been dedicated 500 cfs of pumping capacity at Banks Pumping Plant in July to September. The conveyance capacity would yield approximately 50,000 – 60,000 acre-feet per year, depending on operational restrictions (refer to Chapter 2).

3. *The likely locations, types, and purchase amounts of the water transfers.* In some years, other water acquisition programs would compete with the EWA for water. The exact locations, type and amounts of other programs' transfers are not yet known, so the cumulative analysis examines these effects qualitatively.

---

[1] Wheeling is defined as the transportation of water, as the result of ad hoc contracts or other arrangements, in conveyance facilities which the transferring party does not otherwise have the authority to use (Water Education Foundation 2000).

In general, EWA agencies are committed to reducing any potential cumulative effects. When possible, EWA agencies would work cooperatively with other acquisition programs to avoid water purchases if it would result in a cumulative effect. This coordination would take place through the CALFED Water Transfers Program.

22.1.2 Facility Improvement Projects

Another factor of the cumulative condition is that various proposed projects may alter current water storage, conveyance, or export abilities. Depending on the time needed to plan, design, and construct these facilities, they may affect the cumulative condition within the timeframe of the EWA. Therefore, this chapter (Section 22.2.3) includes with the project descriptions a qualitative assessment of the potential cumulative effects.

22.2 Cumulative Programs and Projects

This section describes future water acquisition programs and facility improvement projects considered in the cumulative analysis and their interrelationship with one another. Other water acquisition programs relevant to the analysis include:

- Sacramento Valley Water Management Agreement (SVWMA);
- Dry Year Water Purchase Program;
- The Governor's Drought Risk Reduction Investment Program (DRRIP);
- Central Valley Project Improvement Act (CVPIA) Water Acquisition Program (WAP); and
- Environmental Water Program (EWP).

Delta facility improvement projects relevant to the cumulative analysis include:

- South Delta Improvement Project (SDIP);
- North Delta Improvements Project (NDIP);
- In-Delta Storage Program; and
- SWP/CVP Intertie.

22.2.1 Other Water Acquisition Programs

The sections below summarize the program descriptions and relevance to the cumulative condition.

22.2.1.1 Sacramento Valley Water Management Agreement (Phase 8)

Over the past several years, the State Water Resources Control Board (SWRCB) has been engaged in seven phases of proceedings regarding the responsibility for meeting the flow-related water quality standards for the Delta established in the 1995 Delta Water Quality Control Plan (Delta WQCP), resulting in Decision 1641. The flow-related standards provide requirements for the amounts of water flowing out from the Delta into the San Francisco Bay to maintain quality parameters within the Delta. The SWRCB hearings have focused on which users should provide this water, and the eighth phase of these proceedings focused on the water users in the Sacramento Valley. Senior water rights holders and water users throughout the Sacramento Valley felt that water releases for Delta water quality could infringe upon their water rights.

In response, the Department of Water Resources (DWR), Bureau of Reclamation (Reclamation), Sacramento Valley water interests, and export water users entered the SVWMA in April 2001, providing an alternative to the Phase 8 proceedings. The SVWMA establishes a process by which local parties are to develop and implement a variety of local water management projects that will increase water supplies cumulatively, meeting both in-basin demands and the Delta water quality requirements set forth in the Delta WQCP. SVWMA proponents plan to implement the SVWMA in water year 2003. In 2005, Phase 8 upstream users are to provide 185,000 acre-feet of water to meet water quality standards through implementation of conjunctive management projects (SVWMA 2002). Current preparations are underway for an EIR/EIS for the program.

The agreement includes a series of work plans that are to be implemented over an 8--year period. Currently, the short-term work plan consists of over 50 locally managed, publicly funded projects that are to be initiated within the 2002-03 calendar years. These projects incorporate the following benefits:

- Facilitation of groundwater management and planning;
- Water conservation and efficiency through facility improvements;
- Fish passage improvements;
- Provisions for water transfers and exchanges;
- Flood protection;
- Conjunctive water management opportunities; and
- Environmental improvements (SVWMA 2002).

An offstream storage project north of the Delta is a key component of the long-term plan. This storage is intended to provide additional water quality benefits to the Delta and provide additional storage space with other environmental benefits.

SVWMA could contribute to the cumulative condition in normal, dry, and critical water years. Signatories to SVWMA would initially seek water during below normal, dry, and critically dry years from reservoirs, groundwater pumping, and groundwater substitution opportunities upstream from the Delta. SVWMA agreement would purchase up to 185,000 acre-feet (SVWMA 2002). SVMWA has conveyance capacity priority over the EWA program. In the long term (5 to 10 years), outside of the EWA program timeframe, the water for SVWMA would likely come from new facilities, eliminating potential conflicts with EWA acquisitions.

22.2.1.2 Dry Year Water Purchase Program

In mid-January 2001, several SWP and CVP contractors requested that DWR and Reclamation initiate planning for a dry year water acquisition program, based on the dry year hydrology to date. DWR announced the 2001 Dry Year Water Purchase Program (Dry Year Program) in March 2001. This program represented the first dry year acquisition program by DWR since the 1991, 1992, and 1994 Drought Bank programs. The Dry Year Program was implemented again in 2002 and 2003, and may be activated in the future to help public agencies throughout California supplement their water supplies in dry years.

The program intends to reduce the possibility of any hardship associated with water shortages through the facilitation of water transfers and is open to SWP contractors, CVP contractors, and third party users. In 2001, DWR provided 138,800 acre-feet of water from willing sellers in northern California to eight SWP contractors (DWR 2002). In 2002, DWR secured 22,000 acre-feet of water from willing sellers in Northern California and provided it to four water agencies throughout the State. In 2003, four public agencies and two private parties have requested a total of 63,000 acre-feet from the program (DWR 2002a). Transfers negotiated between CVP and SWP contractors and other water users, such as the Forbearance Agreement with Westlands Water District and the recent crop idling acquisition by Metropolitan WD from water agencies upstream from the Delta, are considered part of the Dry Year Program. The mandatory reduction in California's use of Colorado River water, discussed in Chapter 2, could increase demand for water upstream from the Delta and increase acquisitions under the Dry Year Program.

During dry years, DWR and Reclamation would likely initiate water acquisitions first from reservoirs upstream from the Delta, followed sequentially by groundwater substitution, crop substitution, and crop idling in areas upstream from the Delta. This acquisition sequence is expected to compete with other programs, including EWA, for available water and pumping capacity. In years that EWA and the Dry Year Program are active, the CALFED agencies would coordinate to provide the needed water amounts for both programs. Conveyance of the Dry Year Program acquisitions for SWP contractors has priority over EWA conveyance.

22.2.1.3 The Governor's Drought Risk Reduction Investment Program

As part of the implementation of the CALFED Plan, the Governor convened a panel to develop plans for California to respond to a future drought. In December 2000, the panel published its report, entitled the Critical Water Shortage Contingency Plan, which is now referred to as the DRRIP. The plan recommended a multi-pronged set of preparations and responses to future water shortages. The water acquisition element of the plan is the Critical Water Shortage Reduction Marketing Program, or CWSRMP. CWSRMP is an as-needed water purchasing and allocation program and is activated whenever parts of the State are suffering from critical water shortages.

The CWSRMP consists of the following three tiers that consider the severity of water shortages and a varying level of State response:

> **Tier 1** applies throughout CALFED Stage 1 and consists of water shortage preparedness activities undertaken by the State and local agencies. These activities would include State actions necessary to prepare for CWSRMP operation, including drafting a PEIS/EIR and developing contract formats for program water purchases. Local agency preparedness activities could include measures for water use efficiency, development of local facilities to enable water transfers, or development of local groundwater management programs. Members on the Governor's panel differed on whether DWR should operate a water purchasing program in Tier 1 (GADPP 2000).
>
> **Tier 2** applies in the early stages of a hydrologic drought or other critical water shortage and includes water transfers. Local agencies making a declaration of probable impending critical water shortages absent a program purchase, and demonstrating that they are maximizing use of their own resources, would be eligible to purchase water. Participants would then pay a price for the water that recovers program implementation costs, including costs for mitigating third-party impacts and environmental impacts identified through the CEQA process (GADPP 2000).
>
> **Tier 3** applies during the later stages of a hydrologic drought or during a water shortage emergency. The trigger for implementing Tier 3 would be a declaration of emergency by a water agency pursuant to Water Code Section 350, by a city or county, or by the Governor. State response to Tier 3 conditions would include continued implementation of Tier 2 actions, plus measures needed to protect public health and safety. These protection measures could include State financial assistance to small water systems for emergency water acquisitions, including water hauling, pipeline construction, or well drilling (GADPP 2000).

DRRIP is designed to reduce the impacts to agriculture and urban users during critical drought periods. DRRIP is expected to acquire water from the Upstream from the Delta Region and the Export Service Area during dry years by first seeking water from reservoirs, then by groundwater substitution, and lastly through crop idling

(DWR 2002). Although DRRIP has not yet defined the details of its water acquisition strategies, the schedule dictates implementation in the next severely dry year after 2002. The Dry Year Purchase Program and DRIPP could combine into one program upon completion of a programmatic document in October 2004 (Jones 2002).

The options are similar to--and potentially in conflict with--those available for EWA upstream water purchases. When both programs are active, the CALFED agencies would work together, seeking to provide the needed water amounts for both programs. DRRIP would have pumping/conveyance priorities similar to the Dry Year Acquisition Program.

22.2.1.4 CVPIA Water Acquisition Program

Section 3402 of the CVPIA identifies the purposes of the CVPIA as protection, restoration, and enhancement of fish, wildlife, and associated habitats in the Central Valley. A requirement of the CVPIA is the acquisition of water for protecting, restoring, and enhancing fish and wildlife populations. To meet water acquisition needs under CVPIA, the U.S. Department of the Interior (Interior) has developed a joint Reclamation and U.S. Fish and Wildlife Service (USFWS) Water Acquisition Program.

The CVPIA requires the provision of firm water supplies to specified National Wildlife Refuges, State Wildlife Areas, and private wetlands in the Grassland Resource Conservation District for the purpose of optimum habitat management on the refuge lands.[2] CVPIA Section 3406(d)(1) requires that the Secretary of the Interior immediately provide specific quantities of water to the refuges and indicates that long-term contractual agreements should be developed for water provided. These are referred to as "Level 2" supplies,[3] for which Reclamation and Interior entered into long-term water supply agreements/contracts with USFWS and California Department of Fish and Game (CDFG). The CVPIA requires delivery of this water in all year types except critically dry water year conditions, as determined by Reclamation for allocation of CVP water. In the case of a critically dry water year, the Secretary of the Interior may reduce Level 2 refuge water supplies by up to 25 percent (USFWS 1998).

Section 3406(d)(2) of the CVPIA refers to "Level 4" refuge water supplies, which are the quantities required for optimum habitat management of the existing refuge lands identified in the "1989 Report on Refuge Water Supply Investigations." The CVP must acquire the increment of water between Level 2 and Level 4 supplies from willing sellers. Section 3406(d)(2) requires that, upon enactment of the CVPIA, Level 4 water be provided in 10 percent cumulative increments per year with provision of full Level 4 supplies after 10 years. Reclamation has been acquiring Level 4 water on a short-term basis from willing sellers since 1992; 2002 is the first year that Reclamation is expected to provide full Level 4 supplies to the refuges. Level 4 water

[2] CVPIA Sections 3406(d)(1) and 3406(d)(2).
[3] See also Chapter 2.

supplies amount to an additional 163,259 acre-feet above Level 2 water supplies (USFWS 1998).

Like EWA acquisitions, CVPIA water acquisitions must not create an involuntary reallocation of CVP yield for refuges. Priority resources for water acquisitions are primarily reservoirs and secondarily groundwater substitution opportunities throughout the State. Idling is also a secondary source of water for CVPIA acquisitions. Strategies for water transfers include use of options, 1-year transfers, groundwater banking, and carryover into the San Luis Reservoir. The CVPIA will purchase up to 120,000 acre-feet from willing sellers during wet and dry years. CVPIA has higher pumping and conveyance capacity priority than the EWA at the CVP pumps, and capacity is shared equally at the SWP pumps (DWR 2002). Detailed coordination among the CVPIA Water Acquisition Program, the Environmental Water Program, and EWA requires Reclamation, USFWS, and other CALFED agencies to determine how to address individual program goals while pursuing joint acquisitions.

22.2.1.5 Environmental Water Program

CALFED agencies created the EWP to carry out flow-related goals of the Ecological Restoration Program (ERP) Plan. The EWP will acquire water from sources throughout the Bay-Delta watershed and provide flows to facilitate:

- Improvement in habitat conditions for fishery protection and recovery;
- Restoration of critical instream and channel-forming flows in Bay-Delta tributaries;
- Improvement in Delta outflow during critical periods; and
- Improvement of salmon spawning and juvenile survival in upstream tributaries as defined by the ERP and ERP Strategic Plan, by purchasing up to 100,000 acre-feet of water per year by the end of Stage 1.

Some of these EWP assets will compliment the EWA. While the EWP focuses on enhancing instream conditions, program managers would also consider potential benefits to offstream resources. The EWP intends to purchase water from willing sellers in its effort to meet program objectives. CALFED agencies intend to first try the program with pilot water acquisitions. CALFED agencies will then evaluate the results to determine the program effectiveness and to refine the EWP framework (CALFED 2002a). Once the CALFED agencies gather sufficient information, they will prepare an environmental document that covers full implementation of the EWP.

The EWP will be operational through the end of the 30-year CALFED Bay-Delta Program (CALFED 2002a). The EWP is designed to make long-term surface water purchases, while EWA is designed to make short-term water purchases from a variety of acquisition sources. It is anticipated that the EWP would focus water acquisitions on Central Valley rivers and streams, with reservoirs upstream from the Delta as

priority sources. Expansion of this geographic area is dependent upon coordination with the CALFED Science Program and other water acquisition programs.

The EWA and EWP programs plan to coordinate efforts to achieve mutual benefits with single acquisitions. These single acquisitions may include joint acquisitions, with funds contributed both by the EWA and EWP, as well as sequential acquisitions, in which assets acquired by one program are sold to the other after the assets have served the initial purpose. Of additional consideration is use of EWP funds to time EWA acquisitions so that water is transferred during ecologically beneficial periods. Additional strategies for water transfers include groundwater banking and long term purchases.

22.2.1.6 Water Acquisition Program Interrelationships

Implementation of the programs above represents the cumulative condition for water acquisitions through 2007. Several relationships among the programs are important to discuss. First, the major constraint on the cumulative condition is the limited Delta pumping capacity. Maximum transfers in the Upstream from the Delta Region by all water acquisition programs would be approximately 600,000 acre-feet in a dry year. Because of conveyance limitations, priority at the Project pumps becomes critical. Several programs, including SVWMA, the Dry Year Program, DRRIP, and, at times, CVPIA WAP, have pumping priority over EWA. If pumping capacity is not available for EWA purchases, the EWA agencies would acquire water from sources in the Export Service Area. Therefore, the location and type of acquisition becomes a factor for operation of these programs. Table 22-1 further illustrates the relationships among the programs.

Table 22-1
Summary of the Cumulative Condition of Water Acquisition Programs

Program	*Frequency/ Year Type for Implementation*	*Status*	*Location Relative to Delta*		*Potential Acquisition and Management Actions*					
			Upstream	*Export Service Area*	*Surface Water Purchase*	*Ground-water Purchase*	*Ground-water Substitution*	*Ground-water Storage*	*Crop Idling*	*Source Shifting*
EWA	Annual	Current	X	X	X	X	X	X	X	X
SVWMA	Critical, Dry, Below Normal	Future	X		X	X	X			
Dry Year Water Purchase Program	Critical, Dry	Current	X		X		X		X	
DRRIP	Critical	Future	X	X	X	X, *Export Service Area*	X		X	
CVPIA WAP	Annual	Current	X	X	X		X		X	
EWP	Annual	Future	X		X	X	X		X	

The preferred location and type of water acquisition is similar among most programs and is based mainly on costs. Water purchases in the Upstream from the Delta Region tend to be less expensive than purchases in the Export Service Area. Typically, the first acquisition priority would be non-Project surface water because

surface water is usually the least expensive source. When surface water is no longer available for purchase, the water acquisition programs would look to groundwater substitution and direct groundwater purchases to acquire water. Temporary crop idling would be the last water acquisition option utilized by most programs.

Furthermore, as indicated in Table 22-1, all the acquisition programs could be operated in a critical water year and most in a dry year. Because surface water transfers in the Upstream from the Delta Region are the least expensive, surface water supplies would not likely provide enough water for needs of all programs during a dry year. Other types of acquisitions, including crop idling, would likely be used. Thus, total water acquisitions from all programs would maximize pumping capacity in the Delta. Therefore, the potential for cumulative effects to occur during dry years is the greatest, as all programs seek to acquire water in the Upstream from the Delta Region through all acquisition types. The Flexible Purchase Alternative analysis evaluates this "worst-case" scenario.

In many instances, the same agencies (DWR and Reclamation) will be involved in the acquisitions or approval of the acquisitions; therefore, agencies would coordinate purchases. Coordination of the programs will be particularly crucial during critical and dry years, when all programs are in operation. Coordination would be facilitated through the CALFED Water Transfer Program.

22.2.2 Delta Facility Improvement Projects

The CALFED ROD identifies potential actions to be implemented or considered during Stage 1 to improve storage and conveyance. Several of the actions are included in the cumulative analysis. This section contains brief descriptions of the projects and their relevance to the cumulative condition.

22.2.2.1 South Delta Improvements Project

The CALFED ROD identifies the South Delta Improvements Project (SDIP) as a way to improve the use of the Delta for conveyance purposes. The intention of the SDIP is to increase conveyance capacity at the SWP Delta export facility to meet water supply demands in the Export Service Area. The SDIP includes several projects intended to maximize diversion capability into Clifton Court Forebay, while providing an adequate water supply for the South Delta Water Agency (SDWA) and reducing the effects of SWP exports on aquatic resources. The major components of the SDIP are:

- increasing the maximum allowable diversion capacity at the SWP Clifton Court Forebay;
- dredging a portion of Old River to improve conveyance capacity;
- constructing permanent operable barriers to improve water supply reliability and water quality;
- dredging local channels to reduce the frequency of barrier operations and to accommodate improvements to existing agriculture; and

- constructing a permanent operable fish control structure at the head of Old River to improve conditions for salmon migrating up and down the San Joaquin River.

CALFED agencies determined that the objectives outlined in the PEIS/EIR could not be met without some of these South Delta improvements (DWR and Reclamation 2002).

22.2.2.1.1 Banks Pumping Plant Increase to 8,500 cfs

This project would involve increasing SWP pumping at the Banks Pumping Plant from the current limit of 6,800 cfs to 8,500 cfs from March 15 to December 15 and modifying existing pumping criteria from December 15 to March 15 to allow greater use of SWP export capacity (CALFED 2000a). The proposed increase in export capacity to 8,500 cfs would allow more water to be moved through the Delta by all acquisition programs during the summer months. Because purchases in the Upstream from the Delta Region are less expensive per acre-foot than purchases in the Export Service Area, water programs could purchase more water with a fixed amount of money in the Upstream from the Delta Region.

Therefore, under the cumulative condition, if an EWA action reduces pumping, the lost opportunity for conveyance would be greater with the increased export capacity than it would be with the existing capacity. Because the EWA must repay export users for water that was not delivered during pumping reductions, EWA would have to repay more water if pumping were reduced from the higher capacity than it would if pumping were reduced at the existing capacity. However, because increased export capacity would be available, EWA agencies could purchase more water upstream from the Delta at lower costs. Presumably, on average, the cost savings available with less expensive upstream purchases would offset the costs of EWA repayments required when reducing pumping at the larger export capacity.

Though not a direct part of SDIP, the CALFED ROD discusses the potential to increase SWP pumping capacity to a maximum capability of 10,300 cfs. This action would be taken only after the increase to 8,500 cfs. The CALFED ROD identifies that new fish screens at the Clifton Court Forebay and Tracy pumping plants should accompany a capacity increase to 10,300 cfs. The ROD indicates 2006 as the starting year for operations and performance testing of the new screens. Pumping capacity would not likely increase to 10,300cfs within the timeframe of the EWA.

22.2.2.1.2 Constructing Permanent Operable Barriers

The SDIP also proposes to dredge and install permanent and operable barriers to ensure adequate quantity and quality to agricultural diverters within the South Delta. The existing temporary barriers have a limited ability to respond to the continually changing hydraulic and environmental conditions in Delta Channels. It is anticipated that if permanent barriers were installed and continuously operated to address Delta concerns, water supply and quality would be improved. If the barriers were in place, water could be transferred, lessening the potential to affect the water quantity, quality, and channel water level needs of water users in the South Delta. Export

capacity could not be increased to 8,500 cfs unless the channels in the South Delta are dredged and the permanent operable barriers are installed.

22.2.2.2 North Delta Improvements Project

The ROD includes components of the North Delta Improvements Project (NDIP) to address flood control, ecosystem restoration, water quality, fisheries, and water supply reliability concerns in the North Delta. Several parts of the CALFED Ecosystem Restoration Program highlight opportunities for ecosystem restoration and flood protection in the area. The North Delta (particularly along the Mokelumne River and Lost Slough) has a lack of river channel capacity for conveying flows from the Sierra Nevada watersheds safely through the North Delta to the San Joaquin River. The following NDIP actions have been identified to address these issues: 1) dredging and setback levees along the north and south forks of the Mokelumne River, 2) providing flood control and habitat restoration benefit on McCormack-Williamson Tract, 3) restoring wildlife and fisheries habitat along the Georgiana Slough, and 4) conducting a study of modifying operating rules for the Delta Cross Channel (DCC) and of the feasibility of constructing a zero to 4,000 cfs screened diversion in the Sacramento River. A project-level EIR/EIS will analyze the first three actions, which will be implemented as a single project. The fourth action will be addressed in a feasibility study (CALFED 2000).

The NDIP action to design and construct floodway improvements in the North Delta would provide conveyance, flood control, and ecosystem benefits. This action includes enlargement of the South Fork of the Mokelumne River to increase conveyance abilities in summer months when the DCC gates are open, enabling more water to be moved through the DCC without the potential of flooding. During periods of high exports, the DCC waters mix with and improve the quality of the San Joaquin flow. When the gates are closed, Delta water quality worsens (CALFED 2000).

This action could affect water acquisition program operations under the cumulative condition. For example, currently, the EWA is required to buy additional carriage water[4] to meet Delta water quality standards. If the Mokelumne River channel were enlarged, more water could move through the DCC, and the EWA would not be required to purchase additional carriage water to maintain water quality standards. EWA Management Agencies would be able to use the money saved from decreased carriage water acquisitions to purchase water for environmental and supply purposes.

22.2.2.3 In-Delta Storage Project

The CALFED agencies have researched various in-Delta storage projects. As part of the investigations, CALFED agencies have explored the lease or purchase of the Delta Wetlands Project, a private proposal by Delta Wetlands Properties Inc. to develop and market a water storage facility in the Delta. The Delta Wetlands Project includes 1) conversion of Webb Tract and Bacon Island into storage reservoirs, termed

[4] See Chapter 5, Water Quality.

"reservoir islands" and 2) conversion of Bouldin Island and Holland Tract into "habitat islands" for wetland and wildlife management and enhancement for environmental mitigation. The storage capacity of the "reservoir islands" is estimated to be 217,000 acre-feet, with a designated water surface elevation at 4 feet above mean sea level (CALFED 2002).

The purpose of in-Delta storage is to help meet the ecosystem needs of the Delta and EWA and CVPIA goals; to provide water for use within the Delta; and to increase reliability, operational flexibility, and water availability for the SWP and CVP water use south of the Delta water. Improved operational flexibility would be achieved by providing an opportunity to change the timing of Delta exports. In-Delta storage would provide a location to which water acquisition programs could convey and store water during pumping restrictions. The Delta Wetlands Project would divert water from the Delta to in-Delta storage during periods of high flow and low impacts on fish and create new points of diversion that could be used selectively to minimize impacts on aquatic resources. Any water stored in the Delta would be readily available for export when restrictions are relaxed.

The In-Delta Storage Program Draft Summary Report, completed in May 2002, evaluated the Delta Wetlands Project for technical and financial feasibility for public ownership. It was the conclusion of DWR that for ownership by DWR or Reclamation, the project as proposed by Delta Wetlands requires modification and additional analyses before it is appropriate to "initiate negotiation with Delta Wetland owners or other appropriate landowners for acquisition of necessary property" (CALFED 2000). The environmental review and documentation, necessary authorization, and funding are expected to be completed in 2005.[5]

The potential effects of the Delta Wetlands Project on water quality and water supply are unknown. Several water quality requirements in SWRCB Decision 1643 are intended to ensure that the Delta Wetlands Project will not create significant water quality impacts. Specific criteria were developed for total organic carbons (TOC), chloride, disinfection byproducts (DBPs), dissolved oxygen, and temperature (CALFED 2002). It is possible that TOCs could increase in the stored water above Delta quality standards and, therefore, constrain the supply available from the Delta Wetlands Project.

The actual operations of the project, including who would operate it and how, are still unspecified. Therefore, it is unknown how the Delta Wetlands Project would affect the cumulative condition. Any water exported through the pumps from the Delta Wetlands Project is expected to have lower priority than the EWA (CALFED 2002).

[5] The ROD deadlines for the In-Delta Storage Program no longer apply, because the CALFED agencies decided to pursue the Re-engineered Delta Wetlands Project instead of the Delta Wetlands Project as proposed by Delta Wetlands Properties, Inc.

22.2.2.4 SWP/CVP Intertie

The ROD identifies the construction of a number of interties and bypasses in the water system. A proposed intertie between the SWP and CVP facilities at or near Tracy could affect the cumulative condition. Currently, the CVP facility has a maximum pumping capacity of 4,600 cfs. The canal downstream from the pump narrows at the final pools, reducing the maximum capacity that can be delivered to O'Neill Forebay to 4,200 cfs. An intertie would be built between the project facilities to accommodate the additional 400 cfs that cannot be moved through the final pool of the canal. The canal would potentially increase export capacity for the programs. For example, if the CVP allocations to its contractors were less than 100 percent, unused capacity in the intertie could provide additional capacity for the EWA to move water through the Delta, assuming that the CVP is not using the capacity for its own purposes. This capacity would typically be available during summer months, but the exact amounts are unknown.

22.2.3 Delta Improvement Projects Interrelationships

The Delta Improvement Projects would facilitate movement of water through the Delta and increase export capacity at the Delta pumps. These projects could effectively increase the amount of water transfers possible for the water acquisition programs under the cumulative condition. Essentially, these programs would allow more purchases to occur than those described under the Flexible Purchase Alternative, which would increase the possibility that all water types would be acquired during all hydrologic conditions. The pumping capacity priorities discussed above would still apply.

Delta Improvement Projects would improve environmental conditions through various means. Increasing capacity at the SWP pumping plant would require new fish screens to be installed. In-Delta storage would provide an immediate water supply for fish actions. The NDIP would address the need for flood control solutions that are integrated with ecosystem improvements. These projects would improve the environment of the Delta, while also improving conveyance and storage capacity.

Cumulatively, the Delta improvement projects would improve water quality in the Delta and water supply to users south of the Delta. Because conveyance would increase, cumulative effects to fisheries could be possible. However, because the projects are in the planning stages, the potential cumulative effects to water supply, Delta water quality, and fisheries are unknown. The environmental documents for the Delta Improvement Projects must address the projects' contributions to increased water acquisition potentials for the EWA and the other water acquisition programs. Currently, no conclusion can be made regarding cumulative effects of the Delta Improvement Projects; therefore, individual resource cumulative analyses do not discuss cumulative effects of these projects.

22.3 Incremental Contribution of the EWA to the Cumulative Condition

Mitigation measures would minimize the potential for EWA acquisitions to significantly contribute to cumulative effects. Detailed coordination between the water acquisition programs, along with EWA implementation of the mitigation measures, would limit adverse cumulative effects. CALFED agencies must determine how individual program goals will be addressed in the pursuit of joint acquisitions. Coordination would occur through the CALFED Water Transfers Program.

22.4 Summary of Cumulative Effects for Individual Resource Areas

Each resource chapter includes an analysis of cumulative effects. The following sections summarize the resource cumulative analyses. Refer to associated chapter for complete discussion of cumulative effects.

22.4.1 Surface Water Supply and Management

Under the water transfer programs, water in the Upstream from the Delta Region would be purchased from stored reservoir surface water supplies, groundwater supplies, and through groundwater substitution and crop idling practices. It is possible that cumulative purchases could draw reservoirs down below the Baseline Condition, lessen the possibility of refill, and affect future users' water supply. It is anticipated, however, that districts selling water to the programs would manage their supplies responsibly so that SWP, CVP, and non-Project users would not be adversely affected. Therefore, no permanent cumulative effects to surface water supply reservoirs would occur.

Water acquisitions through groundwater substitution and crop idling would not result in flow changes that affect nonparticipating users' water supply; therefore, the acquisitions would not result in a significant cumulative effect.

22.4.2 Water Quality

The Flexible Purchase Alternative analysis evaluated the potential impacts to rivers and reservoirs as a percent change in flow, reservoir storage, and water surface elevation. If additional transfer programs draw reservoirs down or reduce riverflows below the acceptable criteria for water quality management, the effects could be cumulatively significant. To prevent cumulatively significant impacts, water agencies would have to cooperatively set release limits on reservoirs such that the reservoirs would not be drawn down below the levels required to maintain suitable water quality levels within the reservoirs, especially during the summer season when water levels are already low within the reservoirs.

River flow rate would most likely be governed by established regulatory requirements for anadromous and riverine fish, through such agencies as USFWS and

National Oceanic and Atmospheric Administration Fisheries, which would prevent flow rates from increasing or decreasing in a manner that would be considered harmful to the fisheries. The fluctuations in flow caused by the cumulative actions would most likely not increase or decrease flows to cause a cumulatively significant impact to water quality.

With regard to cumulative effects to water quality in the Sacramento-San Joaquin Delta Region, the analysis presented in Section 5.2.4.1.4 is not only an evaluation of the Flexible Purchase Alternative as compared to the Baseline Condition, but is also an evaluation of the Cumulative condition as compared to the Environmental Setting/No Action/No Project condition. Therefore, a cumulative effect would not occur.

In the Export Service Area, source shifting would not be expected to lower reservoir levels in Diamond Valley Lake, Castaic Lake, and Lake Perris beyond the levels of the Baseline Condition. Therefore, a cumulative effect would not occur.

22.4.3 Groundwater Resources

The cumulative effects analysis focuses on the regional programs that may affect groundwater rather than on local projects. Crop idling as a water acquisition method during dry years could result in lower groundwater levels because irrigation water would not percolate into the groundwater basin, resulting in adverse effects. However, the EWA agencies would consider other reasonably foreseeable transfers by all water transfer programs when determining where to acquire water through crop idling. EWA agencies would then only purchase water from idling 20 percent of the rice land in a county, where this 20 percent would include the other, reasonably foreseeable transfers.

During dry years more groundwater substitution transfers may occur in the acquisition programs because there will be a greater capacity for transport at the pumps. These cumulative effects could be potentially significant if these programs are not coordinated. It is assumed that each program will institute similar groundwater mitigation measures as those stipulated under the EWA Program. The EWA's groundwater mitigation measures require a pre-purchase evaluation for areas in which groundwater levels (prior to the transfer) are sufficiently low to warrant potential regional adverse effects. If the evaluation shows that EWA extraction would likely result in regional adverse effects, the EWA Project Agencies would not purchase groundwater from the area of concern. The groundwater mitigation measures require that the local selling agencies establish monitoring and mitigation programs prior to EWA transfers.

Consequently, the coordinated implementation of the programs together with the mitigation measures stipulated under the EWA Program would minimize any adverse effects that the EWA Program may contribute to the cumulative effects of all the programs to less than significant.

22.4.4 Geology, Soils, and Seismicity

Water acquisitions through crop idling could potentially affect geology and soils. In the Upstream from the Delta Region, conditions (both existing management practices and weather conditions) are not favorable for erosion of soils. However, loss of surface soils through erosion of bare fields during crop idling is a concern for the Export Service Area where water acquisition programs may acquire water via cotton idling. EWA agencies will require a dust suppression plan to mitigate for significant impacts. Under the cumulative condition, EWA agencies would also require the dust suppression plan; therefore, any effects to the cumulative condition would be less than significant.

22.4.5 Air Quality

In the Upstream from the Delta Region, ozone attainment status is an issue of concern; additional emissions of ozone precursors from other programs would contribute to already high ozone concentration areas, creating a potential significant cumulative effect. Because the EWA is implementing mitigation measures to alleviate a potentially cumulative impact, the EWA's contribution is considered less than significant.

Counties in the Export Service Area are considered severe nonattainment areas for ozone. The production of ozone precursors by several programs could lead to a significant cumulative impact. However, the EWA is implementing mitigation measures listed in Section 8.2.7, which would also alleviate the cumulative impact. Therefore, EWA's contribution is not cumulatively considerable and thus not less than significant.

Crop idling causes increased fugitive dust emissions and associated PM_{10} emissions. Both fugitive dust and PM_{10} are currently at high concentrations in this region. The production of PM_{10} by cumulative crop idling transfers could lead to a potentially significant cumulative impact. However, Fresno, Kern, Kings, and Tulare Counties are within the San Joaquin Valley APCD. The APCD regulates fugitive dust emissions and requires adherence to mitigation measures in the form of a dust suppression plan. Any crop idling transfer program would be required to comply with the APCD regulations; therefore, after mitigation no cumulative impacts would occur.

22.4.6 Fisheries and Aquatic Ecosystems

The analysis of potential cumulative effects to fisheries and aquatic resources is based on a discussion of potential impacts resulting from the comparative analysis of the Flexible Purchase Alternative and the cumulative condition. Implementation of one or more of the water acquisition programs in conjunction with the EWA will not change the total supply of water from upstream sources from that analyzed for the Flexible Purchase Alternative. Because transfers under other programs are managed during the same time periods evaluated for the management of EWA assets, these

increases or decreases in flows would not change, relative to levels identified under the Flexible Purchase Alternative.

Water surface elevation and end-of-month storage levels would not be reduced further than those analyzed for the Flexible Purchase Alternative. Similarly, changes in flow and water temperatures in rivers potentially affected by the EWA cumulative condition also would be similar to those analyzed for the Flexible Purchase Alternative. In the Delta, potential impacts of the Flexible Purchase Alternative were determined by conducting an analysis based on the maximum utilization of available export capacity of Delta facilities, which is the limiting constraint on transfers for the water acquisition programs. Therefore, potential cumulative impacts to reservoir and riverine fisheries and habitats in the Upstream from the Delta Region would be less than significant.

In the Export Service Area, stored reservoir water is not available for purchase, and source shifting would only take place under the EWA Program. Source shifting would not result in reservoir water surface elevations in San Luis, Castaic, Perris, and Diamond Valley Reservoirs lower than those reached under the Baseline Condition. Therefore, potential cumulative impacts resulting from implementation of the Flexible Purchase Alternative in the Export Service Area would be less than significant.

22.4.7 Vegetation and Wildlife

All programs which participate in groundwater substitution will conduct groundwater actions based on individual environmental documents required for the use of CVP and SWP facilities. The oversight of water transfers by Reclamation and DWR would ensure that the effects because of groundwater substitution actions on wetlands and other vegetation communities would be avoided or minimized. Groundwater substitution actions undertaken by other water supply programs would also be limited by water transfer capacities and the same criteria applied to the EWA program. Therefore, groundwater substitution would not present a cumulative effect on vegetation and wildlife resources.

Crop idling by all acquisition programs, including EWA, would be limited by water export capacities. In addition, EWA agencies would consider other reasonable and foreseeable crop idling actions by other water acquisition programs before idling 20 percent of county rice or cotton acreage. These limitations and socioeconomic 20 percent crop idling measure would control the amount of cropland idled for water supply programs. In the Export Service Area, EWA crop idling actions affect cotton crops. Cotton does not provide habitat of value to wildlife; therefore idling of cotton crops under the EWA program would not affect vegetation and wildlife resources. Therefore, crop idling would not present any cumulative effects on vegetation and wildlife resources in both regions.

Stored reservoir water would potentially be purchased in all the cumulative programs. The EWA Flexible Purchase Alternative analysis includes the maximum amount of water available from each reservoir. Therefore, the amount for purchase

either by the EWA or in combination with other projects is the worst-case effect that could occur should all programs purchase stored reservoir water in any single year. Therefore, like the Flexible Purchase Alternative analysis, effects under the cumulative condition would be less than significant.

22.4.8 Regional and Agricultural Economics

Idling of rice fields in the Upstream from the Delta Region and cotton fields in the Export Service Area by all water acquisition programs could result in cumulative economic effects. At the time of the water acquisition, the EWA agencies would consider other reasonably foreseeable transfers when determining where to acquire water through crop idling. EWA agencies would then only purchase water from idling 20 percent of the rice or cotton land. If other water acquisition programs purchase more water through crop idling resulting in greater than 20 percent of rice or cotton acreage, those programs would be responsible for meeting Water Code requirements and addressing the subsequent cumulative effect.

In addition to the EWA, water acquisition programs that purchase water via groundwater substitution would result in further declines of groundwater levels and higher extraction costs for third party users. The EWA would continue to implement its groundwater mitigation measures.

Demands for water transfers are expanding the water transfers market.
Any local or government sponsored transfer program would contribute to the cumulative condition. More participants in the market might drive up the price of transfers. Increased prices should increase the long-run supply of water for transfer.

22.4.9 Agricultural Social Issues

Water transfers via crop idling by all water acquisition programs could result in cumulative effects to farm labor. At the time of an EWA water acquisition, the EWA agencies would consider other reasonably foreseeable transfers when determining where to acquire water through crop idling. EWA agencies would then only purchase water from idling 20 percent of the rice or cotton land. With careful coordination, data collection, and verification, crop idling for the EWA would cumulatively not adversely affect farm labor.

22.4.10 Agricultural Land Use

The cumulative effects analysis considers other water transfer programs that utilize crop idling, land retirement programs, and conservation programs that protect agricultural and open space land. Crop idling by these programs would be temporary and would not permanently alter any land use patterns. Furthermore, EWA land use mitigation measures would not decrease the amount of land categorized as prime, statewide important, or unique. Therefore, EWA would not permanently change land use practices and would not contribute to any cumulative effect. Consequently, because crop idling is temporary and EWA would not

contribute to any changes in land use classifications, any potential cumulative effects on agricultural land use would be less than significant.

22.4.11 Recreational Resources

Other programs in combination with the EWA that purchase water from the same agency could draw down reservoirs further than under the Flexible Purchase Alternative. The additional water sold for other programs would reduce the Baseline Condition described and could cause significant cumulative impacts. EWA Management Agencies would not purchase water from an agency if the purchase would cause a cumulatively significant impact on recreation.

Actions such as groundwater substitution and crop idling in the Upstream from the Delta Region would change in the timing and quantity of water released from reservoirs, altering riverflows. Water transfers from other acquisition programs along the same rivers as in the EWA program area could result in a cumulative effect on the change in riverflow. However, it is not anticipated that the riverflow would change to such a level as to cause a cumulatively significant impact on recreation.

22.4.12 Flood Control

There are no other programs that could store water in Lake Oroville between November and March. If DWR did allow such storage, the lake water surface would be higher, and flood releases, if needed, would be initiated sooner. Flood control regulations would be followed regardless of the type of water stored in Lake Oroville. Therefore, the cumulative effects are considered less than significant.

Agencies participating in groundwater substitution and crop idling with various programs would cause reservoirs to release more water than under the Baseline Condition. The USACE flood control guidelines would limit releases such that the releases were within channel capacity. The cumulative effects are considered less than significant.

No other water transfer programs are currently managing water that involves early delivery of water, and none are likely to do so. Therefore, there would be no cumulative effects on flood control because of predelivery.

22.4.13 Power Production

There is a potential for cumulative effects to CVP/SWP power production for other water acquisition programs that alter the timing of water releases from Project reservoirs. In the past, these programs have included specific terms for use of Project power in contractual documents. Recent year EWA water purchases have been facilitated by terms of Interim Protocol documents. Because the other programs remain in the planning stages, or are subject to CVP/SWP policies that are evolving, operational details of the programs cannot be described. Any power impacts of these programs would not constitute environmental effects, but rather economic losses. Power impacts in the cumulative condition are essentially the same as those shown for the Flexible Purchase Alternative and would be less than significant.

22.4.14 Cultural Resources

Cumulative effects analysis for cultural resources focuses on those programs that potentially acquire water through stored reservoir water purchase and crop idling. Cultural impacts in the cumulative condition are essentially the same as those shown for the Flexible Purchase Alternative and would be less than significant. If any additional water were transferred, mitigation would require a cultural resource inventory and evaluation of property within the added drawdown zone and development of appropriate cultural resource protection to reduce impacts to a less-than-significant level.

22.4.15 Visual Resources

Visual resource concerns stem from the early lowering of the water surface elevation within non-Project reservoirs, creating a larger exposed bank area of the reservoir during the summer recreation season. The EWA analyses address the maximum water available from each reservoir. Additionally, other crop idling programs are currently being implemented and may contribute to cumulative effects on visual resources. However, as previously noted, crop idling is a current agricultural practice that is not a permanent action. It is generally not possible to determine the difference between normal crop rotation and fallowing related to a water transfer. In addition, crop idling involves a Class C scenic area. Idling of rice land (seasonally flooded agriculture) will not affect wildlife viewing during the fall, winter, or spring. Rice land idling is a summer action not affecting migration and over-winter periods for migrating birds. Cumulatively there would be no additional visual resource impact than from that described under the EWA analyses.

22.4.16 Environmental Justice

Environmental justice effects stem from crop idling actions that result in the loss of low-income agricultural jobs (employment). The EWA program has selected two crops to idle, rice and cotton, which require fewer field workers than other crops. The other programs that involve crop idling (Dry Year, DRRIP, and the CVPIA WAP) would most likely also idle only rice and cotton. The EWA agencies would consider other reasonably foreseeable transfers when determining where to acquire water through crop idling. EWA agencies would then only purchase water from idling 20 percent of the rice or cotton land. The cumulative effects of these programs on environmental justice would therefore be the same as the effects described for the Flexible Purchase Alternative.

22.4.17 Indian Trust Assets

This ITA cumulative analysis focuses only on those programs that potentially pose incrementally detrimental effects through groundwater substitution in all areas of the State. As discussed in Chapter 6, Groundwater Resources, all are required to have monitoring and mitigation plans that prevent third party effects, similar to those that apply to EWA actions. Careful monitoring and management is necessary to mitigate any potential effects to a less than significant level. Additionally, all EWA

groundwater substitution acquisitions in the vicinity of an ITA require the United States to be notified before such acquisitions are finalized in order for the United States to fully execute its Indian Trust responsibilities. After deliberation by subject matter experts and appropriate tribal consultation, mitigation may reduce effects to a less-than-significant level.

22.5 Mitigation Measures

Refer to each individual resource chapter for a discussion of mitigation measures.

Chapter 23
Consultation and Coordination

During the preparation of this Draft Environmental Impact Statement/Environmental Impact Report (DEIS/EIR), the lead agencies, Bureau of Reclamation (Reclamation), and the Department of Water Resources (DWR), consulted with resource specialists, agencies with specific expertise in project issues, and members of the public. These consultations assisted the lead agencies in determining the scope of the DEIS/EIR, identifying the range of alternatives and environmental protection and mitigation measures, and defining impact significance. Consultation included informal agency communications, formal interagency meetings, and public meetings. The lead agencies will continue to solicit public and agency input on the project by encouraging review of this DEIS/EIR. This chapter summarizes agency consultations and public involvement efforts conducted during the project planning and environmental review process.

23.1 Fish And Wildlife Consultation

The U.S. Fish and Wildlife Service (USFWS), National Marine Fisheries Service (NOAA Fisheries), and California Department of Fish and Game (CDFG) are CALFED agencies and are acting as cooperating agencies on the Environmental Water Account (EWA) DEIS/EIR. USFWS, NOAA Fisheries, and CDFG consultation is being undertaken consistent with the CALFED Plan as described in the following.

The CALFED Bay-Delta Program is a collaborative effort of 23 federal and state agencies that seek to resolve water supply conflicts in the Bay-Delta. The CALFED Programmatic Record of Decision (ROD) set forth a collaborative means for addressing the environmental effects (adverse and beneficial) of CALFED actions related to improving water supply reliability and recovery/restoration of the Delta environment and species dependent on the Delta. Through the implementation of the Multi-species Conservation Strategy (MSCS) process, the CALFED agencies assessed the effects of potential CALFED actions on targeted species, and then developed initial conservations measures that when implemented would meet the overall CALFED objectives.

One of the goals of the CALFED MSCS is to address combined compliance with the federal endangered species act (FESA), California endangered species act (CESA), and the California Natural Community Conservation Planning Act (NCCPA) requirements. The MSCS serves as the biological assessment of the programmatic CALFED actions. USFWS and NOAA Fisheries used the MSCS as the biological assessment to develop the programmatic biological opinions for the programmatic CALFED actions. CDFG used the MSCS for compliance with the CESA and NCCPA.

For second-tier CALFED project actions such as the EWA, an Action Specific Action Plan (ASIP) is required to address the FESA, CESA, and NCCPA consultation requirements of federal and state agencies. As a tiered document, the ASIP focuses on

issues specific to the EWA Proposed Actions. This ASIP therefore addresses the biological assessment requirements. The USFWS and NOAA Fisheries will use this ASIP to develop action-specific biological opinions relative to the EWA. The CDFG will use this ASIP to address compliance with the CESA and NCCPA.

23.1.1 Consultation To Date

As described above, Fish and wildlife consultation was conducted in coordination with the development of the ASIP. Issues pertaining to the ASIP have been discussed within an ASIP Team comprised of representatives from Reclamation, DWR, USFWS, CDFG, and NOAA Fisheries. The ASIP reports USFWS, NOAA Fisheries, and CDFG findings regarding impacts to identified endangered, threatened, and proposed or candidate species that may occur in the action area.

April 17, 2002---ASIP team discussed the Detailed Work Plan for Task 7 (Fish and Wildlife Consultation), the overall ASIP process and schedule, and the ASIP's relationship to the EWA.

May 1, 2002---ASIP team discussed crop idling and methodology for producing the species list.

May 6, 2002---Reclamation and DWR representatives discussed with CDFG impacts on water districts and clarify methodology for developing the species list.

May 22, 2002---CDFG and CALFED discussed an outline for the ASIP, impacts, water districts including Kern Water District, and general progress.

June 5, 2002---ASIP team discussed appropriate maps used to determine species distribution within the EWA action area.

July 23, 2002---Reclamation, CDFG, USFWS, Attorney General's Office, and CALFED discussed ASIP preparation. Discussion centers on methodologies for assessing impacts and geographical division on the project area.

September 11, 2002---ASIP team discussed the proposed document review process for September and October and the revised Table of Contents.

September 20, 2002---The ASIP team discussed the ASIP review process, a revised Table of Contents, the ESA definition of baseline, the species and Natural Community Conservation Plan (NCCP) Communities lists, the Crop Idling Impact Assessment Approach, and the ASIP settings. Also discussed at this meeting was whether the ASIP will be part of the EIS/EIR or act as a stand alone document and whether this is a Reclamation ESA consultation or whether all five agencies share joint responsibility for the consultation.

September 26, 2002---The ASIP team discussed the ASIP review process, Hydrologic Modeling for potential impact determination, thresholds of significance, the impact assessment approach for reservoir covered species, and indirect, interrelated, and

interdependent effects. The hydrologic modeling text was provided in advance for review during the meeting.

October 4, 2002---The ASIP team discussed structure, format, and content of the draft ASIP. Specifically the team discusses the hydrologic modeling section, Table of Contents, ESA Baseline, Impact Analysis, and Project Description.

October 10, 2002---Representatives from USFWS, CDFG, Reclamation and CALFED meet to discussed ESA baseline definitions and effects analysis approach, conservation measures, and content of draft ASIP.

23.2 Indian Trust Assets And Native American Consultation

EWA agencies are responsible for evaluating Indian Trust Assets (ITA) impacts. Section 20.3.3 contains avoidance criteria that reduce effects to a less than significant level. In the event an impact is identified, consultation with affected recognized tribal governments proceeds through the proponent agencies, the Bureau of Indian Affairs (BIA), the Office of the Solicitor, and the Office of American Indian Trust.

Tribal consultation would proceed any formal EWA groundwater transfer in the vicinity of potentially affected tribes. Government-to Government consultation shall take place to determine interests, concerns, impacts, applicable tribal regulations, and appropriate avoidance measures. Consultation may involve EWA agencies, BIA, and the Regional Solicitor's Office.

23.2.1 Consultation to Date

August 1, 2002---Representatives from Reclamation meet with BIA to introduce EWA and initiate discussion on possible hydrogeologic criteria that could identify potential impacts on ITAs. Potential impacts require Reclamation to notify and consult with trust land owner.

August 8, 2002---Reclamation and BIA met to continue discussion about establishing operating rules that would require Reclamation to initiate ITA consultation. Reclamation proposed a structure for the consultation process.

September 12, 2002 ---Representatives from Reclamation, CDM, and Public Affairs Management met to develop appropriate outreach involvement processes and material for the general public, farm labor, and Native Americans. Discussed issues related to Environmental Justice, tribal involvement, and Indian Trust Assets.

23.3 National Historic Preservation Act/State Historic Preservation Officer Consultation

The National Historic Preservation Act (NHPA) of 1966 (as amended in 1992) requires federal agencies to consult with the Advisory Council on Historic Preservation concerning potential effects of federal actions on historic properties. To comply with

the NHPA, notices of public meetings for this project have been sent to the State Historic Preservation Officer (SHPO), which acts as an intermediary for the Advisory Council on Historic Preservation. A copy of this DEIS/EIR has been sent to SHPO, as a unit of the California Department of Parks and Recreation, requesting its review and soliciting input on the project. Reclamation will continue to coordinate with the Advisory Council on Historic Preservation and SHPO, consistent with Section 106 of the National Historic Preservation Act.

23.3.1 Consultation To Date

Formal consultation with SHPO was initiated by a letter request from Reclamation dated February 5, 2003. In this letter, Reclamation recommended that due to the nature of the proposed EWA actions, a Programmatic Agreement would be the most appropriate vehicle for the treatment of historic properties. SHPO responded to Reclamation in a letter dated March 11, 2003. In this letter, SHPO stated its agreement that a Programmatic Agreement is the most appropriate approach for dealing with historic properties.

23.4 Environmental Justice

Executive Order 12898, Section 2-2, signed by President Clinton in 1994, requires all federal agencies to conduct programs, policies, and activities that substantially affect human health or the environment, in a manner that ensures that such programs, policies, and activities do not have the effect of excluding persons (including populations) from participation in, denying persons the benefits of, or subjecting persons to discrimination because of their race, color or national origin. Section 1-101 requires federal agencies to identify and address, as appropriate, disproportionately high and adverse human health or environmental effects of programs on minority and low-income populations.

State law defines environmental justice in Government Code Section 65040.12(e) as the fair treatment of people of all races, cultures, and incomes with respect to the development, adoption, implementation, and enforcement of environmental laws, regulations, and policies. Government Code Section 65040.12(a) designates the Governor's Office of Planning and Research (OPR) as the coordinating agency in state government for environmental justice programs, and requires OPR to develop guidelines for incorporating environmental justice into general plans.

The Bay-Delta Public Advisory Committee has an Environmental Justice Subcommittee composed of federal and state agency representatives, tribal members, community-based organizations, advocacy groups, and others interested in achieving environmental justice. As mandated by the ROD, CALFED agencies are committed to ensuring that all its programs and agencies are committed to seeking fair treatment of people of all races, cultures, and incomes, such that no segment of the population bears a disproportionately high and adverse health, environmental, social, or economic impact resulting from CALFED's programs, policies, or actions.

23.4.1 Consultation to Date

October 11, 2002 --- The EWA Actions were discussed at the CALFED Bay-Delta Public Advisory Committee Environmental Justice Subcommittee meeting. At this meeting, DWR requested input from conference members on development of a mechanism for a cost and reimbursement structure for compensating impacts on third party laborers potentially affected by water transfers.

23.5 Public Involvement

The following is a summary of the public involvement activities including public informational and environmental process scoping meetings for the project. Further discussion of these activities and the issues identified for evaluation in the EIS/EIR are presented in the July 2001 Public Scoping Summary Report, available through lead agency contacts. (See the Abstract for lead agency contacts.)

23.5.1 Environmental Impact Statement/Report Scoping

Reclamation published the Notice of Intent (NOI) to prepare an EIS and Notice of Public Scoping Meeting pursuant to the National Environmental Policy Act (NEPA) in the *Federal Register* on July 6, 2001. This notice was accompanied by a press release issued by CALFED announcing the public scoping meetings, which was mailed to approximately 500 interested individuals, stakeholders and organizations. In addition, DWR issued Notice of Preparation (NOP) of an EIR pursuant to the California Environmental Quality Act (CEQA) to resource agencies and interested members of the public on July 10, 2001. Copies of the NOI and NOP are included in Appendix F.

Public scoping meetings for EWA were held throughout the State of California to provide the public with an update on the status of the project and to identify additional significant issues to be addressed in the EIS/EIR. The public scoping meetings were held in Sacramento, CA, on July 19, 2001; Chico, CA, on July 19, 2001; Oakland, CA, on July 23, 2001; Tracy, CA, on July 24, 2001; Bakersfield, CA, on July 25, 2001; and Los Angeles, CA, on July 26, 2001. Attendees included agency staff members, local residents, representatives from various organizations, representatives from various federal, state, and local government agencies, and the media.

At each public scoping meeting, a project overview presentation and public comment session were provided. During the first portion of the meetings, representatives of the lead agencies, CDFG, and USFWS discussed the environmental documentation process and the elements of EWA. Agency representatives then presented a CALFED overview, including components of the CALFED program, description of tiered environmental documents, and an overview of EWA. A public comment session followed, at which time written comments were received and oral comments were recorded. A scoping report was prepared to summarize the public comments received at the scoping meetings.

23.5.2 Summary Of Public Concerns

The comments received at the public scoping meetings, as well as those received in response to the NOI and NOP, are summarized below by major topic. Consultations with resource agencies and the professional judgment of the specialists involved in preparation of the DEIS/EIR further defined the impact issues that are addressed in impact analyses in Chapters 4 through 20.

23.5.2.1 Resource Related Issues

23.5.2.1.1 Water Supply and Water Management

- Address the effects and limitation on Delta exports.
- EWA proposes increased exports, but decreased protection from those exports. The tidal barriers partially mitigate the export pumps' effects on water levels and quality. If barriers must be removed for increased exports, users will lose protection against exports in order that exporters may not be affected.
- The use of EWA to compensate for overages in the (b)(2) accounting procedures is risky and probably not feasible. EWA obligations may be extremely large, exceeding its ability to compensate for reduced deliveries. The EWA may not be able to acquire enough water through use of its variable assets to cover upstream fish protections formerly charged to (b)(2).
- EWA water from south of Delta purchases is of water previously exported in a manner that harms South Delta water levels, quantity and quality.
- DEIS/EIR must address how much less water is available downstream as well as when it is no longer available for each EWA purchase, and what the effects of such decreases are both individually and cumulatively.
- Model the effects of realistic increased EWA exports and identify when those opportunities for increased diversions may exist and what potential limitations may further affect the ability to accomplish such EWA exports.
- Mitigation for withholding water from human consumption for fish protection during or following successive drought years may be needed.
- The analysis must address how the program would function during multi-year droughts (e.g., 1928-1934).
- Where will the water come from without hurting non-state and federal water project users? What protections would be established.
- Will EWA effectively reduce food production in one area only to promote food production in another area?
- Do not send water south---south of the Delta is already over-committed.

- The statement that EWA water will be acquired in a manner that results in no adverse impacts on Central Valley Project (CVP) and State Water Project (SWP) contractors is incorrect in that the protection does not apply to CVP contractors other than export contractors.

- Analyze how purchases of stored water upstream of the Delta would affect Reclamation's ability to meet the Vernalis salinity standard, the amount of water available for CVP contractors from the subject reservoir, and the amount of water available for fisheries downstream of the subject reservoir.

- Since EWA does not rely on new water supplies, the purchases are only a reallocation of already insufficient supplies.

- EWA proposes to purchase water from suppliers who will substitute groundwater but have no less consumptive use. It also proposes to purchase water from diverters who will decrease their return flows to the waterways and/or capture more water than before. Each of these actions will have significant long-term effects on the water supplies and quality of waters in the Sacramento-San Joaquin system.

- Purchase of water from upstream of the Delta will necessarily adversely impact other water users because these purchases decrease the amount of water carried over in reservoirs. Reclamation is choosing to help its export contractors at the expense of its upstream contractors, what is the justification for taking water away from fish in one place to help fish in another?

- The barriers are mitigation for the export projects' adverse effects on South Delta water levels, quantity, quality, and circulation, and use of EWA will harm South Delta diverters. What is the basis for concluding that the existing regulatory actions are insufficient, and are the projects not currently mitigating their effects on fisheries? It is unclear whether the EWA, in combination with other protective mechanisms, will have enough "assets" to ensure the timely restoration and recovery of fish and wildlife.

23.5.2.1.2 Water Quality

- Address salinity levels.

- Address lack of ability to meet the Vernalis and three interior South Delta water quality objectives for agricultural beneficial uses.

- The EIS/EIR should address the interrelationship between EWA and (b)((2) releases, particularly as related to the releases from New Melones. Shift in releases of water affect the ability of New Melones to meet the Vernalis salinity standard.

- How will the timing and volume of asset movement affect water quality?

- Evaluate whether source shifting or other types of asset acquisition would have an impact on water quality.

23.5.2.1.3 Groundwater Resources

- Address groundwater supplies/overdraft in the San Joaquin Valley.
- Address overdraft of groundwater basins and supply for times of drought.
- The EIS/EIR should also analyze the cumulative effect on increasing the net long-term overdraft of groundwater. If water is shifted from food production to environmental use there will be an increase in groundwater overdraft in an attempt to maintain crop production where a shift from surface to groundwater is possible.

23.5.2.1.4 Fisheries and Aquatic Resources

- Identify species that have been impacted by EWA operations and the degree of significance to any impacts.
- Identify impacts of past operations on fisheries and what the likely adverse effects will be in the future.
- Include analysis regarding the effect of the EWA in reducing, stabilizing, or increasing Bay-Delta estuary fishery populations.
- Include all certain future water acquisitions, from either existing or new water sources, in the analysis.
- Identify methodology for determining which water users must pay for EWA benefits.
- Consider enhancement/restoration of flows in the Consumnes River for improved anadromous migration.
- How will the success or benefit of EWA, as a part of many actions taken to recover listed species, be measured? Include an analysis of EWA actions and expenditures to determine fishery benefits, not only to evaluate the program but also to help shape future actions.
- Explain how competing fish needs will be resolved [e.g., striped bass (predator target species), exotic species].
- Why worry about killing a few fish in the river when commercial harvest is so high, and new areas are soon to be opened up for additional commercial fishing?
- It has not been established that the water allocated to Tiers 2 and 3 of EWA will actually achieve fish recovery because CALFED scientists have not reviewed the scientific basis of the account. Not only has CALFED failed to show that the EWA will assist fish recovery, but also has failed to consider whether there are other non-flow practices that would be more beneficial to fish.

- Recognize and evaluate the interrelationship between the river and groundwater---to determine true impacts to fish and wildlife.

- It is unclear whether the EWA will have enough assets to ensure the timely restoration and recovery of fish and wildlife.

- Since it is not possible to predict exactly when fish most need either additional flow or reduced exports to maximize their probability for survival, it makes sense to monitor fish distributions and movements and, at least to some degree, to manage Delta flows and exports in response to these factors.

23.5.2.1.5 Agricultural Land and Water Use

- Address impacts to agricultural resources.

- Use the California Agricultural Land Evaluation and Site Assessment (LESA) model to assess impacts to agricultural resources.

- Submit CALFED's Land Use Checklist with the environmental documentation whenever agricultural resources are affected by programs and projects.

- Mitigation measures must be considered and consistent with measures identified in the CALFED Record of Decision (CALFED ROD).

- The conversion of agricultural water resources has significant direct, indirect, and cumulative impacts that must be considered in the EIR/EIS.

- The EIR/EIS should evaluate the loss of export capacity for north-Delta transfers by agricultural water users, and identify how purchases will impact the CVP and SWP and whether the EWA will disproportionately impact the CVP.

- Government agencies should not protect the production of food by export water users at the expense of decreasing crop production elsewhere.

- The EIS/EIR must analyze the extent to which water is now used for production of food will be acquired for EWA.

- Evaluate how the EWA may affect our net food supply.

23.5.2.1.6 Agricultural Economics

- Address impacts to agricultural production and the economy.

- Increases of the salinity above the salinity threshold for each crop cause a proportional decrease in crop production and results in harm to the diverter.

- The Farm Bureau believes that the CALFED Programmatic Environmental Impact Statement/Environmental Impact Report is legally inadequate, as CALFED insufficiently considered the impacts associated with the reallocation of agricultural

resources. To the extent that the future environmental review of the EWA tiers from the legally insufficient EIS/EIR, the environmental review of the EWA will be fatally flawed.

23.5.2.1.7 Power Production and Energy

- Include explanation of how adverse impacts to CVP water and power production customer deliveries, and costs will be avoided.
- How will asset management be coordinated with energy production?
- An analysis of the power costs and re-directed impacts related to power use and production must be conducted, including changes in on- and off-peak pumping.
- How will the change in management of power companies due to divestiture affect the availability and need for assets? Need to recognize that historic management of co-generation is changing and may affect the program.
- Power impacts need to be evaluated to determine the feasibility of an action.

23.5.2.2 Other Issues

23.5.2.2.1 Project Descriptions

- The EIR/EIS should clearly explain how decisions on acquisition of EWA assets are made, who makes them, where the funds come from to pay for them, and who benefits from the transactions.
- Project location must be more closely specified.
- Include specific criteria used to "target" water acquisitions.
- The EIR/EIS must address the project location and total quantities of water to be acquired through the annual and final implementation of the program.
- Determine what regions of the state will be the potential targets of redirected impacts.
- Include details of the process for extending the program.
- Specify duration of the program.
- Address cumulative effects of 4+-year purchase program.
- Address costs of water available for purchase.
- Address the effects and limitation on exports from the Delta.
- The purpose is to ensure there is no increase in consumptive use of water resulting from the transfer.

- Section 3405 specifically prevents transfers that result in a net increase in consumptive use.

23.5.2.2.2 Alternatives

- Desalination should be evaluated as a source of water for EWA.
- Include historic transfers and Delta operations in the No-Action Alternative.
- Describe how failure to acquire assets will be dealt with.
- Consider alternatives that encourage agricultural management practices.
- Alternatives should only include purchases of water made available from a decrease in consumptive use or a decrease in water previously lost to consumptive use.
- Alternatives should address priorities for access to project facilities.
- Evaluate various mixes of assets and how they may need to change over time.
- Give water districts opportunities to sell water that might otherwise spill.
- Consider other alternatives such as habitat modifications, changing fishing regulations, and utilizing EWA assets to modify other project operations (e.g., power plants) in the western Delta region.
- Consider alternatives that fund the account through volume-based user fees.
- The traditional regulatory approach should still be used to protect all life stages of fish, as well as their food base, low salinity habitat and other ecosystem elements.
- Identify a process where CALFED agencies can ensure that EWA and private water transfers are complementary and not competitive.
- Where will water come from to bank for the south?
- Create procedures for how and when it is appropriate to elevate the EWA to Tier 3.
- The EIS/EIR should consider how the EWA might be utilized in ways other than for augmenting stream flows and modifying/replacing exports. These alternatives could include habitat modifications, fishing regulation changes, and modifying other project operations in the Delta.

23.5.2.3 (b)(2) and CVPIA

- EWA and Central Valley Project Improvement Act (CVPIA) (b)(1) and (b)(2) are designed to provide for environmental benefits. How will these programs be

coordinated or integrated to achieve their purposes, and how will their implementation affect SWP and CVP operations?

23.5.2.4 Cost and Funding

- How much will this program cost taxpayers?
- A cost-benefit analysis should be conducted for the program.
- Willing sellers should not profit from the sale of water to the EWA, and purchase prices should reimburse sellers for actual costs.
- Value of water for sale should equal the cost associated with the permit or license pursuant to Water Code Section 1392 and 1629.
- Ensure cost of purchases are in accordance with market pricing.
- Consider alternatives that fund the account through volume-based user fees.
- Why should there be no uncompensated water cost to project users? Will all taxpayers pay for something that benefits project water users?
- In order to keep supplies to Kern County Water Agency (WA) at the current levels, the EWA buys back water from Kern County WA at a price that gives Kern County WA a substantial profit. Wouldn't it be cheaper to simply not deliver that amount of water to Kern County WA? Why is this paper exchange of water (but real exchange of money) not a gift of public funds?
- Analyze how regulatory baseline relates to project obligations to mitigate damages to fish and wildlife. Compare EWA baseline to obligation to mitigate impacts. Is EWA providing a benefit above the obligation?
- The EIR/EIS must first determine what the specific effects of the export projects are on fisheries in order to comply with Water Code Sections 11900 et seq. Those statutes require that the projects include as a reimbursable cost (paid by the contractors) amounts sufficient to pay for the preservation of fish and wildlife. Cost of enhancement of fish and wildlife are not reimbursable. Hence, the projects must first determine their effects on fish and wildlife and charge their contractors for the preservation thereof. Thereafter, actions/costs for the enhancement of fish and wildlife may be borne by programs such as the EWA. Absent this determination, expenditures to cover statutorily mandated reimbursable costs would be an illegal gift of public funds.
- The fact that the EWA does not provide benefits to all water users dependent on the watershed is another solid argument for user fees.
- Any program undertaken by state agencies to expend taxpayer funds to pay for costs which are statutorily allocated to private parties would constitute an illegal gift of public funds.

23.5.2.5 General

- How long would the program last? The duration of the program affects opportunities for the program and potential willing sellers.
- Will EWA operate similarly to a "bank account" carrying over from year to year?
- How will this document handle the impacts of an asset acquisition when the specifics of that acquisition are not known at this time?
- Consider lessons learned during the first year.
- Address ESA assurance: is EWA doing what it is supposed to do, i.e., 2001 short on assets, but still got assurances backstop protection, Tier 3 was not available.
- Is EWA large enough? Need to reevaluate the size of EWA on a regular basis.
- The programmatic document should be supplemented on an annual basis.
- CALFED must review the scientific justification for the amount of water already purchased and proposed to be purchase for the EWA.
- EWA water purchases are for recovery, not jeopardy, thus the water in this account is not water that necessarily would be taken through regulation if it were not purchased by the government. Moreover, even if this water were taken through regulation, it is not necessarily true that the water contractors would not be paid for the water, especially in light of the Tulare Lake Decision.
- The CALFED ROD states that the EWA is intended for "fishery protection and restoration/recovery needs as part of the overall Ecosystem Restoration Program." Thus, the EWA is a critical tool to achieving overall restoration goals. Indeed, this function is the only justification for any state or federal funding for the EWA. It is essential that planning for the EWA reflect these co-equal objectives of the EWA.
- The scope of the EWA must not be expanded without additional assets and careful evaluation of the ability of the EWA to meet any added burden.
- The cumulative effects of all acquisition programs need to be addressed.
- Provide for a technical peer review of the analysis of hydraulics of the Delta.
- Use PROSIM for the analysis because CALSIM is not fully trusted.
- EWA re-directs an impact related to use of barriers at the time EWA assets are in use---this must be evaluated in the environmental document.
- Evaluate the impacts associated with the proposed annual operational changes.

- If the EWA water allocation was based on computer modeling, the EIR/EIS should explain how the outcome of this modeling relates to the ultimate size of the EWA.
- Would the EWA program exert control of private property and water rights?
- How will instream flow transfers be addressed?
- The state and federal acquisition programs need to be coordinated.
- What is the scientific basis for and relationship between the Environmental Water Program and the EWA?
- The EWA would cause negative impacts to south-Delta agricultural contractors through competition for available transferable water. Impacts would include increased prices, decreased water supply of transferable water, decreased export capacity, increased fallowing, and increased groundwater pumping.
- Parties who are riparian to or permitted diverters from such channels are entitled to the natural flow. At any time that San Joaquin River flows are inadequate for Delta riparian or senior water holders needs, no party with junior appropriative rights on the Sacramento system can store or divert water necessary for those downstream riparians or permitted diverters. During the months of October to December, Middle River is sometimes dry. Any refill of upstream reservoirs during that time would therefore be depriving riparians and senior rights holders of the Middle River to water they are entitled to.
- Profit cannot be made of the transfer of any rights under a permit or license to divert water.
- The EIS/EIR should include scenarios in which the EWA, with and without Tier 3 protections, is inadequate to provide required fish protections and the environmental impacts of the reduced fishery protection, of any additional mitigation measures that could be required by the situation, and in curtailment of water project operations that may result.
- Individual water bank facilities, and more specifically the Kern Water Bank, should prepare supplemental environmental documentation regarding the substantial change to their individual operations as a result of this project.

23.5.2.5.1 Management of Assets

- Will surplus water be a source of EWA assets?
- Will the EIS/EIR describe how failure to acquire assets will be dealt with?
- What happens to EWA assets if the Coordination Operation Agreement or Operations Criteria and Procedures changes?
- How can we be assured that assets can be acquired this year and future years?

- How will the mix of assets need to change over time?
- Operational flexibility is a must.
- It doesn't make sense to buy from those who are not getting their full entitlement.
- Ensure that EWA assets are real.
- The EWA is not intended to be used to assure a given level of water diverters to any South-of-Delta water user that is not explicitly included in the EWA baseline.
- Define and provide the Tier 3 water supplies.

23.5.3 Public Review Of Draft EIS/EIR

The Public Draft EIS/EIR is available for review and comment for 60 days following filing of the Notice of Availability (NOA) of the EIS with the U. S. Environmental Protection Agency and the Notice of Completion (NOC) of the EIR with the California State Clearinghouse.

The NOA and notice of public hearing on the EIS were published in the *Federal Register*. The NOC was filed with the California State Clearinghouse.

The purpose for public review of the DEIS/EIR is to receive comments from interested parties on its completeness and adequacy in disclosing the environmental effects of the proposed project. Following the close of the DEIS/EIR public review period, a second document containing comments received on the DEIS/EIR and responses to the significant environmental points raised in those comments, will be prepared and published. Together, the DEIS/EIR and the responses to comments will constitute the Final EIS/EIR. Reclamation is responsible for adopting the EIS as adequate in compliance with NEPA, and DWR is responsible for certifying the EIR as adequate in compliance with CEQA. After adoption and certification, the agencies will use the EIS/EIR in making their determination whether to approve the project.

Chapter 24
List of Preparers and their Qualifications

Name/Professional Discipline	Expertise and Experience	Role in Preparation
EWAT Preparer		
Nina Bicknese Environmental Specialist Reclamation	20 years experience in biology, wetland ecology, NEPA/ESA	NEPA compliance, Purpose and Need statement, technical editing, ASIP preparation
Delores Brown CEQA Program Manager DWR	22 years consulting experience in public and private sectors	CEQA compliance, Project Objectives, guidance, review, and oversight
Scott Cantrell Staff Environmental Scientist Dept. of Fish & Game	18 years of experience in population and community ecology in the public sector	ASIP preparation; EIS/EIR project description, impact assessment methodology, coordination, and review
Jerry Johns, DWR EWA Coordinator DWR	28 years of public sector experience in water resources	coordination, oversight, and guidance
Brian Kinnear Protected Species Biologist National Marine Fisheries Service	31 years of public sector experience in fisheries biology and Section 7 Consultation	project description, plan formulation, alternative formulation, plan evaluation, preferred alternative identification, and alternative impact analysis
Sandy Osborn Project Manager Reclamation	22 years public sector experience in environmental planning and management	contract administrator and reviewer
Dave Robinson EWA Program Coordinator Reclamation	20 plus years experience in water and biological resources in the public and private sectors	guidance, coordination, and oversight
Tim Rust Interim Program Coordinator Reclamation	20 plus years experience in water resources planning and wastewater master plan development in the public and private sectors	oversight and review
Curtis Spencer Principal Engineer DWR	35 years public and private sector CEQA and NEPA experience in NEPA/CEQA documents, water resources planning and design	project description and review
Chuck Vogelsang Senior Environmental Scientist CALFED	26 years public sector experience in environmental planning for water resources	oversight and coordination
Hanspeter Walter Environmental Scientist DWR	5 years public sector experience in scientific research and analysis	impact analysis review and contribution
Jim White Environmental Scientist Dept. of Fish & Game	25 years public sector experience in Central Valley anadromous fish and water project operations	aquatic resource coordination, ASIP preparation, project description, plan formulation, alternative formulation, plan evaluation, preferred alternative identification, and alternative impact analysis
Victoria Poage Fish & Wildlife Biologist Fish & Wildlife Service	19 years public sector experience in fishery science	Delta fisheries coordination and review; ASIP preparation
Ryan Olah Fish & Wildlife Biologist Fish & Wildlife Service	5 years public sector experience in endangered species compliance	ASIP preparation, Delta fisheries review, Giant Garter Snake Initial Consultation

Name/Professional Discipline	Expertise and Experience	Role in Preparation
CDM Preparers		
Dave Auslam Senior Economist	20 years experience as resource economist and environmental consultant	economics and agricultural social guidance and review
Courtney Black Environmental Engineer	2 years experience in water quality/hydrologic engineering and wetlands studies	author groundwater resources
Coral Cavanagh Editing/Writing	14 years consulting experience; 12 as planner/engineer with CDM	technical review, editing, and writing
Melanie Craig Environmental Engineer	2 years experience in water resource consulting	author visual resources
Joel Elliston Environmental Technician	3 years experience in environmental consulting	author regional and agricultural socioeconomics, grow-inducing impacts, and institutional and legal framework
Sandra Lunceford Planner	6 years experience environmental consulting and environmental community relations	author Indian Trust Assets, agricultural social issues, cultural, and environmental justice
Carrie Metzger Task Manager	5 years experience in water resources consulting	author introduction and alternatives and proposed action; oversight; review
Patricia Reed Biologist	4 years experience environmental consulting	author vegetation and wildlife, ASIP production
Auturo Smith Senior Drafter	11 years experience engineering technician	drafting/graphics
Gina Veronese Planner	1 year experience in socioeconomic planning and environmental consulting	author regional and agricultural economics, fisheries and aquatic ecosystems, water quality, and cumulative impacts
Michelle Wilen Planner	3 years experience environmental consulting	author water supply and management; geology, soils, and seismicity; air quality; recreational resources; flood control; production
John Wondolleck Project Manager	25 years experience environmental resource management	guidance, oversight, and review
SWRI Preparers		
Meryka Atherstone Environmental Planner	1.5 years experience environmental consulting	author water quality, power production and energy, cumulative impacts, and visual resources
Paul Bratovich Principal Scientist	19 years fishery consulting experience	fisheries, ASIP, guidance and review
Allison Dvorak Associate Water Resource Scientist	3 years environmental consulting experience	CVP/SWP water supply modeling, instream temperature modeling, salmon mortality modeling, associated technical analyses
Jeanie Hinds Associate Environmental Scientist	1.3 years environmental consulting experience	author fisheries, ASIP
Patti Idlof Senior Environmental Planner	19 years experience environmental planning consulting experience	ASIP, resource agency coordination, ESA/NCCP compliance, document review
Carol Lazzarotto Task Manager	18 years experience in environmental consulting	introduction to environmental setting, impacts, and mitigation measures, document review
Jason Lemieux Associate Water Resources Scientist	5 years experience in water resources and fishery modeling	CVP/SWP water supply modeling, instream temperature modeling, salmon mortality modeling, associated technical analyses
Buzz Link Task Manager CALSIM Post-Processing Modeling	11 years consulting experience in water resources, modeling, and power operations	CALSIM post-processing, author power production, modeling

Name/Professional Discipline	Expertise and Experience	Role in Preparation
SWRI Preparers (cont'd)		
Allison Niggemyer Associate Environmental Scientist	1.5 years consulting experience in water quality and fisheries	Water quality analyses
Tami Mihm Senior Environmental Planner	15 years experience environmental and water resources consulting	CEQA/NEPA, permitting and regulatory compliance, water quality, ASIP, ESA/NCCP compliance, document review
Dave Schuster Project Manager	30 years experience environmental consulting	guidance, oversight, alternative formulation, delta fisheries evaluation, modeling, and document review
Dianne Simodynes Associate Environmental Scientist	9 years experience environmental consulting and watershed analysis	fisheries, ASIP
Nissa Wuench Planner	7 months of consulting experience	fisheries settings

ATTACHMENT 1
MODELING DESCRIPTION

1.0 Introduction

The Environmental Impact Statement/Environmental Impact Report (EIS/EIR) for the Environmental Water Account (EWA) Program includes an evaluation of potential impacts upon environmental resources that may result from the purchase, storage, and conveyance of EWA assets and the actions taken by the EWA to benefit fish populations. Flow-related impacts for the resource areas included for analysis in the EWA EIS/EIR are based upon the results of hydrologic modeling, including the CALSIM II 2001 benchmark study (BST_2001D10A), and other related studies as described in this attachment.

The EWA EIS/EIR provides an assessment of the Flexible Purchase Alternative, the Fixed Purchase Alternative, and the No Action/No Project Alternative. Under the Flexible Purchase Alternative, EWA agencies may purchase between 35 thousand acre-feet (TAF) and 600 TAF annually from areas in the Upstream from the Delta Region and the Export Service Area. The Fixed Purchase Alternative represents management of annual EWA water assets of 185 TAF from areas within the Upstream from the Delta Region and the Export Service Area, with a maximum of 35 TAF obtained from the Upstream from the Delta Region. The No Action/No Project Alternative is defined as the reasonable foreseeable future condition without the EWA, based on legal and regulatory constraints. Detailed descriptions of these alternatives are provided in Chapter 2 of the EWA EIS/EIR.

The resource impact analyses evaluate the potential effects of the Flexible Purchase Alternative in a quantitative manner, based on the hydrologic, water temperature, salmon mortality modeling, and the Central Valley Project (CVP) and State Water Project (SWP) pumping plants salvage calculations performed for the project, and described in this document. The Fixed Purchase Alternative is evaluated in a qualitative manner, although the data generated by the Flexible Purchase Alternative analysis is used to approximate the in-Delta fishery benefits produced by the EWA with implementation of the Fixed Purchase alternative. Overall, the water quality, fisheries, and power resources flow-related impacts considered less than significant for the Flexible Purchase Alternative also would be considered less than significant for the Fixed Purchase Alternative. Additionally, as described in Chapter 2 of the EWA EIS/EIR, the Baseline Condition basically represents the No Action/No Project Alternative; therefore, there would be no utility in developing an additional simulation and conducting such a comparison. Therefore, the No/Action/No Project alternative is not addressed further in this attachment.

This document provides detailed information regarding the hydrologic modeling tools, primary assumptions, model inputs, and methodologies used to evaluate potential environmental effects of the EWA Flexible Purchase Alternative upon the resource areas that may be affected by the coordinated operations of the SWP and CVP facilities (Projects) within the EWA area of analysis. The evaluation of potential impacts compares the effects of conveying water from the area of purchase to the Delta and the effect of pumping that water from the Delta via the California Aqueduct and the Delta Mendota Canal to O'Neill Forebay. The area of analysis

(study region or action area) for each resource topic is defined within the resource-specific chapter of the EWA EIS/EIR.

The impact assessments in the EWA EIS/EIR for water quality, fisheries, and power resources are based on comparisons made between computer model simulations developed to represent hydrologic, regulatory, structural and operational parameters for a Baseline Condition (existing, without project) and the Flexible Purchase Alternative (future, with project). Modeling tools used to simulate these conditions include the Department of Water Resource's (DWR's) CALSIM II (released July 23, 2002, with a 2001 level of development [LOD]) the U.S. Bureau of Reclamation's (Reclamation's) water temperature and salmon mortality models, as well as related pre- and post-processing applications utilized to develop the simulations and evaluate the Flexible Purchase Alternative relative to the Baseline Condition.

Because there can be no certainty in forecasting which combination of potential water assets will be available to the EWA Program on a year to year basis, the resource area analyses are subject to error regardless of the assets selected for evaluation. In an effort to capture the maximum effect of EWA purchases by resource area, multiple methods of simulation post processing were employed. Specifically, the first method describes the maximum effects on the locations of water purchase and the second method describes the maximum effects of utilizing the purchased water.

In the first method, four post-processing simulations were performed to identify regional effects of EWA water purchases. Each simulation utilized a single specific asset from the Upstream from the Delta Region (Sacramento River, Feather River, Yuba River, American River, and San Joaquin River) to meet the available July through September EWA export. The simulation was performed for each year of the modeling period of record. Since no single region has sufficient assets to meet a 600 TAF export need, there are many years when all of a region's assets are used but EWA exports are not met. For this methodology, however, regional upstream impacts to vegetation, wildlife, visual, recreation, and flood control resource areas are maximized (magnitude of reservoir drawdown, amount of idled acreage) due to the frequent and total use of the assets. Detailed results from these four simulations are provided in Appendix H, Summary and Technical Output for the Graphical and Tabular Analysis for Environmental Resources (GATAER), of the EWA EIS/EIR.

Because any single simulation in the first method cannot meet the total EWA export potential, a second method was used to maximize impacts associated with EWA exports. This second method was incorporated in a single simulation using all available EWA assets from the Upstream from the Delta Region to meet the maximum EWA export potential (limited to 600 TAF). The simulation was performed for each year of the modeling period of record. This methodology was used for the analysis of potential effects on fish, water quality, Project water supply and management, and power resource areas because it imposes the largest overall change to instream flows and Delta operations. Detailed results from this simulation are provided in Appendix H of the EWA EIS/EIR.

Additionally, two water purchase scenarios that are subsets of the second method described above were created to better evaluate potential effects on fish, water quality, and power resources within the Delta Region. The Delta assessment involved consideration of two separate EWA water purchase scenarios under the Flexible Purchase Alternative 1) Maximum

Water Purchase Scenario; and 2) Typical Water Purchase Scenario. The Typical Water Purchase Scenario assumes a range of EWA asset water purchases from the Upstream from the Delta Region depending upon water year type. Although referred to as a "typical" scenario, this scenario, like the Maximum Water Purchase Scenario, assumes that all unused Delta export pumping capacity for the summer months (July through September) would be available to the EWA Program. While this assumption permits evaluation of the potential worst-case for EWA export pumping, there are other water acquisition and transfer programs and SWP/CVP programs that have priority access to use this available pumping capacity. Therefore, this scenario does not necessarily represent the conditions that would be expected to occur for any given year of the program. Instead, this scenario may be considered to represent conditions that are more likely to occur than those assumed for the Maximum Water Purchase Scenario. The reasons for developing these two separate water purchase scenarios and the key assumptions for each are provided in Section 2.2.2.2.

This document also describes the evaluation assumptions and methodologies developed to determine the net benefit to Delta fish species of primary management concern based upon an assessment of anticipated reductions in fish salvage at the Projects' Delta facilities. The results of the Delta salvage evaluation are included in this document, as well as in Chapter 9 of the EWA EIS/EIR, and in Chapter 4 of the Action Specific Implementation Plan (ASIP). See Glossary of EWA EIR/EIS for definition of terms.

1.1 Purpose and Implementation of the EWA Program

The purpose of the EWA is to provide a highly flexible, immediately implementable, water management strategy with a primary focus of protecting at-risk native fish species affected by CVP/SWP operations and facilities through improvement of aquatic habitat conditions and contribution to the recovery of Delta-dependent native fish species of concern. The EWA is intended to improve aquatic habitat conditions primarily by using EWA assets to reduce CVP/SWP Delta export pumping during periods (months) critical to fish species listed as threatened, endangered or as candidate species under either the Federal Endangered Species Act (ESA) or the California Endangered Species Act (CESA), or both. Additionally, the EWA Program is designed to provide for the timely management of water resources in response to changing environmental conditions and fish protection needs, delivery of reliable water supplies to south of Delta water users, and prevention of uncompensated water costs to the Projects' water users.

The Flexible Purchase Alternative would permit the purchase and acquisition of up to 600 TAF of water assets annually, to apply toward the attainment of CALFED goals and EWA objectives to reduce existing conflicts between the various uses of water resources in the Delta. Implementation of this alternative assumes maximum surface water contributions from identified available contributory sources (see EWA EIS/EIR, Chapter 2). Asset acquisition and water management under this alternative encompasses areas both in the Upstream from the Delta Region and the Export Service Area.

The EWA agencies can utilize variable operational assets and acquire fixed assets (assets), and then allocate water to improve targeted fisheries resources (fish actions or EWA actions). Variable operational assets include flexibility in regulatory requirements (relaxation of Export/Inflow (E/I) ratio for the purpose of providing benefits to fish) and SWP pumping of

instream improvement flows upstream from the Delta utilizing Central Valley Project Improvement Act (CVPIA) section 3406 b(2) and Ecosystem Restoration Program (ERP) water. Fixed assets are water purchased from willing sellers. The EWA agencies evaluate the available assets and select appropriate actions according to a monthly accounting system and practices as determined by the needs of the system and availability of water.

The CALFED agencies managing the EWA Program consider a variety of factors or variables in their decision-making process regarding water purchases prior to and during each water year. In this manner, the agencies must adaptively manage the program to ensure sufficient assets are acquired to enable the agencies to provide benefit to Delta fish resources. Several key factors that affect this decision-making process are listed below:

- The amount of funding available for that years water purchases.
- The amount of export capacity available to the EWA at the Banks and Tracy pumping plants during periods that the EWA must convey water through the Delta to O'Neill Forebay.
- The amount of water that will be purchased upstream of the Delta, which depends on the available export capacity, the amount of funds available for water purchases, the amount of EWA water required that year, and the amount of water available for purchase.
- The amount of variable assets that may be available in a specific year, especially with respect to the amount of water the EWA may gain through relaxation of the E/I ratio.
- The amount of CVPIA b(2) water available to support pumping reductions at the CVP's Tracy Pumping Plant.
- Unknown and variable hydrologic conditions.
- Unknown and variable climatic conditions, with ambient temperature being the most important climatic variable because of the affect of water temperature on fish migration, spawning, and other life stages.

2.0 Impact Analysis Framework

This section describes the impact analysis framework developed to evaluate potential flow-related impacts upon water quality, fisheries, and power resources due to implementation of the EWA Program. Specifically, the hydrologic and related modeling analyses (water temperature and salmon mortality) and post-processing applications were utilized to simulate the operations associated with the Flexible Purchase Alternative. The overall intent of the modeling simulation comparisons was to evaluate the potential effects of conveying EWA assets (water) from the area of purchase (Upstream from the Delta Region) to the Delta and the effects within the Delta associated with pumping the water from the Delta via the CVP and SWP facilities to the O'Neill Forebay. The results of the modeling simulation comparisons are presented in the EWA EIS/EIR, Chapter 5, Water Quality; Chapter 9, Fisheries and Aquatic Ecosystems; and Chapter 16, Power.

The impact analysis framework also describes the evaluation of the benefits realized for Delta-dependent fish species that result from the implementation of the EWA fish actions. The level of benefit derived from the Flexible Purchase Alternative is determined based upon calculations of anticipated reductions in fish salvage at the Projects' Delta pumping facilities. Reductions in fish salvage would occur due to implementation of the EWA fish actions that reduce export pumping volumes during months when fish species of concern are known to be present in the Delta. As discussed in Section 1.0, Introduction, the information generated by the Flexible Purchase Alternative is used to approximate the Fixed Purchase Alternative fishery benefits and effects due to pumping water purchased from the Upstream from the Delta Region at the CVP and SWP pumping plants. (Refer to Section 2.2.2.3.)

2.1 Models Used for the Hydrologic Impact Analysis

Computer simulation models of water systems provide a means for evaluating changes in system characteristics such as carryover storage, reservoir water elevation, river flow rate and power generation, as well as the effects of these changes on environmental parameters such as water temperature and early-lifestage Chinook salmon survival. The models used to simulate the Baseline Condition and Flexible Purchase Alternative include the following:

- DWR and Reclamation Simulation (CALSIM II) model of the integrated CVP and SWP system operations;
- Yuba River Basin Model (HEC-5) developed by Bookman-Edmonston Engineering, Inc. in collaboration with DWR;
- Post Processing Tool for the evaluation of EWA water purchases (EWA Water Purchases.xls);

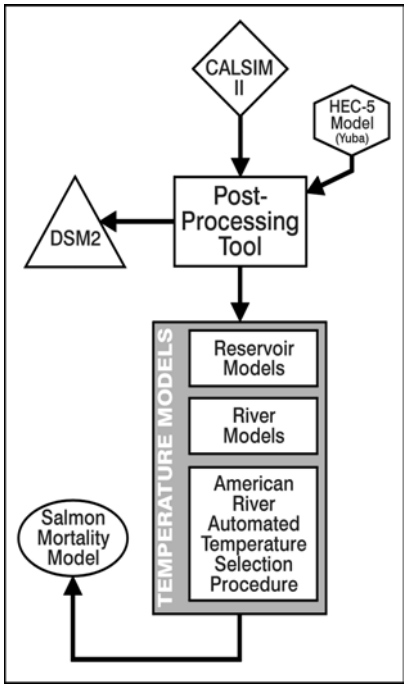

Figure 1
Schematic diagram of the hydrologic modeling process

- Post Processing Tool to route the EWA water purchases and produce the "virtual" CALSIM II output databases (EWA Routing.xls);
- Reclamation Trinity, Shasta, Whiskeytown, Oroville, and Folsom reservoir water temperature models;
- Reclamation American, Feather, and Sacramento river water temperature models;
- Reclamation American and Sacramento river early-lifestage Chinook salmon mortality models;
- GATAER Tool; and
- DWR Delta Simulation Model II (DSM2); the delta hydrodynamic and salinity model for water quality.

A schematic diagram illustrating the hydrologic modeling process is provided in Figure 1. CALSIM II provides a benchmark monthly simulation of the CVP and SWP water operations without any EWA actions. Output from CALSIM II and the HEC-5 model were then used as input to post-processing tools, EWA Water Purchase.xls and EWA Routing.xls, to develop the EWA Actions and the "virtual" CALSIM II output databases for the EWA

analysis. CALSIM II provides hydrologic information for the reservoirs (inflows, reservoir releases, and storage), rivers (flow), and other operating parameters (Project pumping). Many of these parameters are used as impact indicators in the EIS/EIR (see Chapters 5, 9, and 16 for additional detail; also see GATAER output in Appendix H of the EWA EIS/EIR).

The "virtual" CALSIM II output databases were then used to generate the inputs required for the DSM2 and temperature models. The temperature model output was then used to generate the inputs to the early lifestage Chinook salmon mortality models.

Finally, the GATAER tool was used to generate the information needed for the impact analysis in the form of tables and graphs for the outputs of the previous modeling.

These models and related post-processing tools are described in the following sections.

2.1.1 CALSIM II Model

CALSIM II is currently DWR's and Reclamation's primary operations and planning model for SWP and CVP project operations. The model simulates CVP and SWP system operations and the hydrologic effects of those operations within the geographical area affected by CVP and SWP facilities, including the Delta. The major Central Valley rivers, reservoirs and Project facilities are represented by a network of computation points or nodes.

CALSIM II uses a mass balance approach to simulate the occurrence, regulation, and movement of water from one river reach (computation point or node) to another. At each node, various physical processes (e.g., surface water inflow or accretion, flow from another node, groundwater accretion or depletion, and diversion) can be simulated or assumed. Operational constraints, such as reservoir size and seasonal storage limits or minimum flow requirements, also are defined for each node. The model uses a monthly time step. Accordingly, flows are specified as a mean flow for the month, and reservoir storage volumes are specified as end-of-month content.

CALSIM II simulates monthly operations of the following water storage and conveyance facilities:

- Trinity, Lewiston, Whiskeytown, and Shasta/Keswick reservoirs (CVP);
- Spring Creek and Clear Creek tunnels (CVP);
- Lake Oroville (SWP);
- Folsom Reservoir and Lake Natoma (CVP);
- New Melones Reservoir (CVP);
- Millerton Lake (CVP);
- Tracy (CVP), Contra Costa (CVP), and Banks (SWP) pumping plants;
- San Luis Reservoir (shared by CVP and SWP); and
- East Branch and West Branch SWP reservoirs.

To varying degrees, nodes also define SWP/CVP conveyance facilities including the Tehama-Colusa, Corning, Folsom-South, and Delta-Mendota Canals and the California Aqueduct.

Other non-SWP/CVP systems tributary to the Delta are also modeled in CALSIM II, including:

- New Don Pedro Reservoir;

- Lake McClure; and
- Eastman and Hensley Lakes.

The model simulates one month of operation at a time, sequentially from one month to the next, and from one year to the next for 72 years. Each decision that the model makes regarding stream flow regulation is the result of defined operational requirements and constraints (e.g., flood control storage limitations, minimum instream flow requirements, Delta outflow requirements, diversion assumptions) or operational rules (e.g., preference among reservoirs for releasing water). Certain decisions, such as the definition of water year type, are triggered once a year, which affects water delivery allocations and specific stream flow requirements. Other decisions, such as specific Delta outflow requirements, are dynamic from month-to-month. CALSIM II output is represented by flow or storage conditions at each node on a mean monthly basis.

Although a set of EWA actions is built into the CALSIM II model, the actions in the model do not match the EWA actions evaluated in the EWA EIS/EIR. Because the intent of the analysis performed in the EIS/EIR is specifically to evaluate the EWA Program, the modeling operations performed with CALSIM II were halted before the model encountered the conditions specific to EWA implementation. The CALSIM II benchmark study "wrapper" included regulatory constraints defined to include D-1485 through CVPIA b(2).

This was done so that the program conditions pertinent to the EWA Flexible Purchase Alternative would be analyzed separately from all of the other CALSIM II parameters. After the modeling process utilizing CALSIM II was halted, the post processing tools (EWA Water Purchase.xls and EWA Routing.xls) were used to evaluate the conditions specific to EWA and its implementation.

2.1.2 Yuba River Basin Model

The Yuba River Basin Model is a HEC-5 model that has been developed and maintained by Bookman-Edmonston Engineering, Inc. in cooperation with DWR. Bookman-Edmonston Engineering, Inc. continues to collaborate with DWR to refine the system's operating criteria and update information on facilities, inflows (unimpaired flows), demands, and fishery flow requirements (Bookman-Edmonston 2000). The original HEC-5 operational parameters and criteria were obtained from DWR's HEC-3 model and these assumptions have undergone periodic modifications to reflect operational changes within the system as they have occurred.

HEC-5 is a general purpose program that simulates the operation of flood control and water conservation systems. Like CALSIM II, it relies on mass balance reservoir routing logic to simulate the occurrence, regulation, and movement of water from one river reach (computation point or node) to another. Various physical processes (e.g., surface water inflow or accretion, evaporation rates, flow from another node, groundwater accretion or depletion, and diversions) are simulated or assumed. Operational constraints, such as reservoir size, seasonal storage limits, minimum power generation quotas, or minimum flow requirements, also are defined for each node. The HEC-5 model uses a monthly time-step and an upstream-to-downstream procedure to simulate the operations of major water facilities in the Yuba River Basin (Bookman-Edmonston 2000).

2.1.3 EWA Water Purchases.xls Post Processing Tool

The EWA Water Purchase.xls spreadsheet post-processing tool was developed to compute the magnitude and timing of potential EWA actions. Development of this tool was necessary because the CALSIM II model is presently incapable of simulating the range of EWA actions contemplated for the Flexible Purchase Alternative evaluated in the EWA EIS/EIR. Results obtained using EWA Water Purchase.xls post processing tool were then used in the EWA Routing.xls post processing tool. (Refer to Section 2.1.4.)

The EWA Water Purchases.xls spreadsheet post-processor tool was utilized to perform the following functions:

- Redistribute SWP and CVP Delta exports during July, August, and September;
- Identify EWA Delta export volumes for July, August, and September;
- Identify EWA upstream from the Delta water sources used for exports;
- Perform an initial upstream from the Delta routing to check operational constraints; and
- Identify carriage water requirements associated with the EWA actions.

These functions are described in greater detail in the following sections.

2.1.3.1 Redistribution of State Water Project/Central Valley Project Delta Exports

The CALSIM II simulation results include Delta export operations at the Banks and Tracy pumping plants. An examination of the pattern of SWP/CVP exports during the summer months (July through September) shows a model preference for using nearly all of the available Delta export capacity in September with decreasing usage in August and July. This export pattern makes it difficult or, in some cases, impossible to export EWA assets that are available in August and September. For example, EWA assets obtained from crop idling in August and September would be unusable by the EWA program if the water cannot be exported in those same months. Similarly, use of water assets obtained from groundwater substitution or surface water purchases would be limited to those months when Delta export capacity is available to the EWA Program at the Projects' pumps.

The EWA Water Purchase.xls Tool was utilized to redistribute SWP/CVP summer exports during the July through September period to provide for use of EWA assets throughout these months. This redistribution assumed that the total amount of SWP/CVP exports for the summer would not be altered from the amount in the CALSIM II simulation results (referred to as the unaltered condition) and that DWR and Reclamation would cooperatively resolve any issues that arise related to SWP/CVP Coordinated Operations Agreement (COA) responsibilities, as is done on a regular basis under current practices.

Because the redistribution of SWP/CVP Delta exports over the summer months would alter the timing of releases from upstream Project reservoirs, control was maintained on maximum and minimum releases. Redistribution of exports was not allowed to increase Keswick releases above 15,000 cubic feet per second (cfs), Oroville releases above 12,000 cfs, and Nimbus releases above 5,000 cfs. Minimum releases from the Project reservoirs were identified as those necessary for instream environmental requirements or diversion (Wilkins Slough). In the post processor tool, releases from the Project reservoirs for the summer period were temporally altered in response to the redistribution of exports, but were in total volume no more or less

than under the "unaltered condition". In real-time, however, DWR and Reclamation operators would have to approve this type of operation on a case-by-case basis.

2.1.3.2 EWA Delta Export Volumes (July through September)

Subsequent to the redistribution of SWP/CVP exports, the EWA Water Purchase.xls tool was used to determine the amount of export capacity available for EWA assets. These calculations were based on the unused Banks and Tracy pumping plant capacities and allowable E/I ratio, as described below.

The initial determination of export capacity available for EWA asset water was calculated for the Tracy Pumping Plant as the difference between the monthly CVP export (average flow rate) and the pumping plant capacity, 4,600 cfs. At the Banks Pumping Plant, the initial export capacity available for EWA asset water was calculated as half of the difference between the monthly SWP export (average flow rate) and the authorized pumping plant capacity, 6,680 cfs, plus, the EWA variable asset, 500 cfs. In instances where CVP pumping at the Banks Pumping Plant did not require half of the difference, the unused share of this capacity was available for EWA use (see EWA EIS/EIR, Chapter 2, Relaxation of the Section 10 Constraint).

SWP/CVP exports from the Delta are subject to restrictions imposed by the E/I ratio. EWA exports were assumed to comply with this ratio; therefore in some months, available EWA exports were further limited (or controlled) by the E/I ratio. Because increasing EWA exports above the E/I ratio to 0.65 during the July to September period would incur an immediate 35 percent (1.00 - 0.65) loss in EWA water entering the Delta, there was no attempt to maximize EWA exports with the E/I ratio controlled.

2.1.3.3 EWA Upstream from the Delta Region Water Sources

Potential upstream from the Delta EWA assets are described in Chapter 2 of the EWA EIS/EIR. Identifying the location, amount, and type of potential individual water purchases in the Upstream from the Delta Region is critical to determining the instream flow, water temperature, reservoir storage change, and potential water quality effects of the EWA Program. There are numerous possible combinations of water purchases in the Upstream from the Delta Region. Multiple studies to analyze all of the combinations were not feasible because of the time and cost of such an effort.

Because the assets are of varying quantity and type (surface water supplies and/or groundwater supplies), priorities should be assigned to the assets based on the ability of the source to effectively correspond with the temporal EWA export capability. To that end, as listed below, surface water supplies generally were given high priority because of their ability to be used at nearly any time; groundwater substitution supplies were assigned the next highest priority, and supplies made available from crop idling was given the lowest priority. In many years, some portion of all of the available asset types were used in order to maximize the amount of EWA export water.

The EWA agencies prioritized the types and amounts of water purchases in the Upstream from the Delta Region, as follows:

- Water will be purchased first from the Upstream from the Delta Region, limited by the available SWP and CVP export capacity, and second from sellers in the Export Service Area.

- Purchases from reservoir storage will be used before any other purchase option is pursued.

- Stored groundwater purchases will be pursued as a second option after all reservoir storage purchases have been utilized.

- Groundwater substitution purchases will occur if more water were needed than can be obtained from reservoir storage and stored groundwater purchases.

- Water purchases obtained from idling rice will be pursued as a final option if more water were required to satisfy EWA requirements.

- Idling rice in the Feather River Basin will be pursued before idling rice in the Sacramento River Basin because some water from Sacramento River purchases could not be stored in Lake Shasta during April, May, and June when instream water temperature obligations require the water to be released.

2.1.3.4 Upstream from the Delta Region EWA Water Routing

Once the Upstream from the Delta Region EWA assets were selected and total quantity assumed for the specific analysis for a given month, the water was routed through the system of reservoirs and rivers conveying the water to and through the Delta. This routing imposed the appropriate operational constraints and allowed for the computation of changes in reservoir storage resulting from the proposed EWA operations. Physical system limitations were complied with in all months that EWA assets were acquired or used.

Oroville Reservoir Storage

The following discussion on reservoir storage is specific to Oroville Reservoir and is presented to illustrate why there are monthly operational changes in upstream reservoirs caused by EWA purchases. A similar discussion would describe the conditions at Shasta Reservoir, although the actual net changes in reservoir storage would be less.

CVP/SWP monthly reservoir operations would be altered by the implementation of the EWA Flexible Purchase Alternative. Exactly how the reservoirs would be affected is a function of the monthly pattern of CVP/SWP Delta exports, which in turn dictates the availability of monthly export capacity for the EWA.

CALSIM II modeling of the Baseline Condition favors SWP Delta export pumping in September with less reliance on export pumping in August and July. Oroville releases for SWP export pumping also uses the same export-pumping pattern. As a consequence of the timing of releases for SWP export pumping, Oroville storage remains higher in July and August than it would be if SWP export pumping (and consequently releases) occurred more evenly throughout July through September.

To illustrate differences in monthly Oroville storage associated with alternative timing of SWP exports, the CALSIM II Baseline Condition was post-processed to simulate a more even

distribution of SWP exports from July through September. This post-processing did not alter the total July through September SWP export volume; it only changed the monthly pattern of export pumping. In the following discussion, this post-processed simulation is referred to as the "Alternative (Alt) Baseline."

Figure 2 illustrates the average Oroville end-of-month storage for the 1922-1993 modeling period for the Baseline Condition, Alt Baseline, and Flexible Purchase Alternative simulations. The end of June reservoir storages for the Baseline and Alt Baseline are identical as are the end of September storages for the Baseline and Alt Baseline. Only the July and August storages differ between these simulations, reflecting the alternative SWP Delta export patterns. As Figure 2 shows, SWP export pumping in September under the Baseline Condition simulation results in higher Oroville storage during July and August.

Also shown in Figure 2 is a trace of Oroville storage from the EWA Flexible Purchase Alternative simulation. This trace shows that Oroville storage at the end of June is higher than both of the Baseline and Alt Baseline Conditions because of the preservation of water from idled lands in months prior to July. In July and August, the Oroville storage under the Flexible Purchase Alternative falls below the Baseline Condition storage but is higher than the "Alt Baseline" storage. By the end of September, Oroville storage is essentially identical for all three simulations.

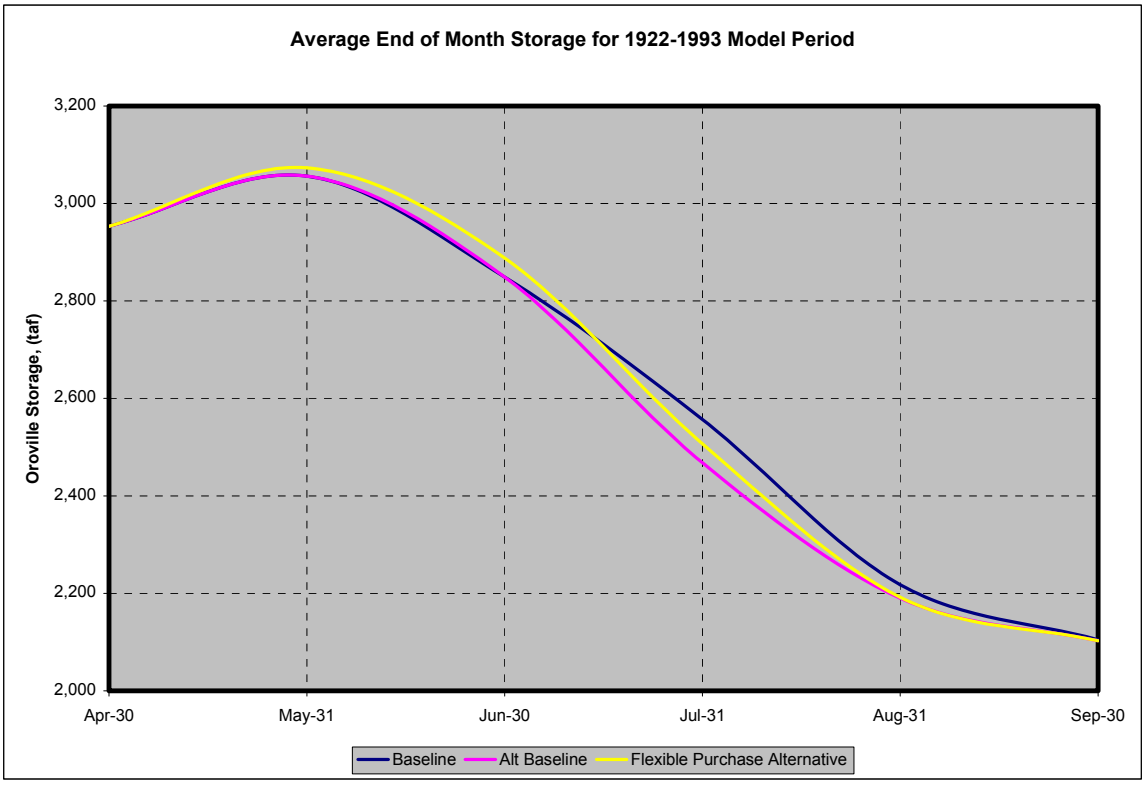

Figure 2 Average Oroville End-of-Month Storage for the 1922-1993 Model Period

Figure 3 illustrates the pattern of end-of-month water use by those entities idling land in the Feather River Region for the purpose of EWA sales. The general agricultural water use pattern,

without the EWA, is shown in the Figure 3 as Pre EWA Use. The Flexible Purchase Alternative in Figure 3 shows the water use pattern with EWA actions. The chart shows the periods when water purchased by the EWA would be released into the rivers. As shown in Figure 4, by the end of July and continuing through August, the cumulative (agriculture and EWA) water use by the Flexible Purchase Alternative exceeds the typical agricultural water use. However, agricultural water use (Pre EWA use) is greater than the Flexible Purchase Alternative use in September and the cumulative volume difference in water use of the purchased water nets to zero by the end of September.

In the instance of the Alt Baseline, there is a presumption that the SWP will alter its Delta export pumping from that assumed in the CALSIM II Baseline Condition simulation. If this were true, then the Flexible Purchase Alternative operation would result in comparatively higher Oroville reservoir storage in July and August. Alternatively, if the SWP maintains the pattern of Delta exports assumed in the Baseline Condition simulation, the Flexible Purchase Alternative would cause lower Oroville reservoir storage in July and August. The Project operators would determine if this pattern of use were acceptable on a real-time case-by-case basis.

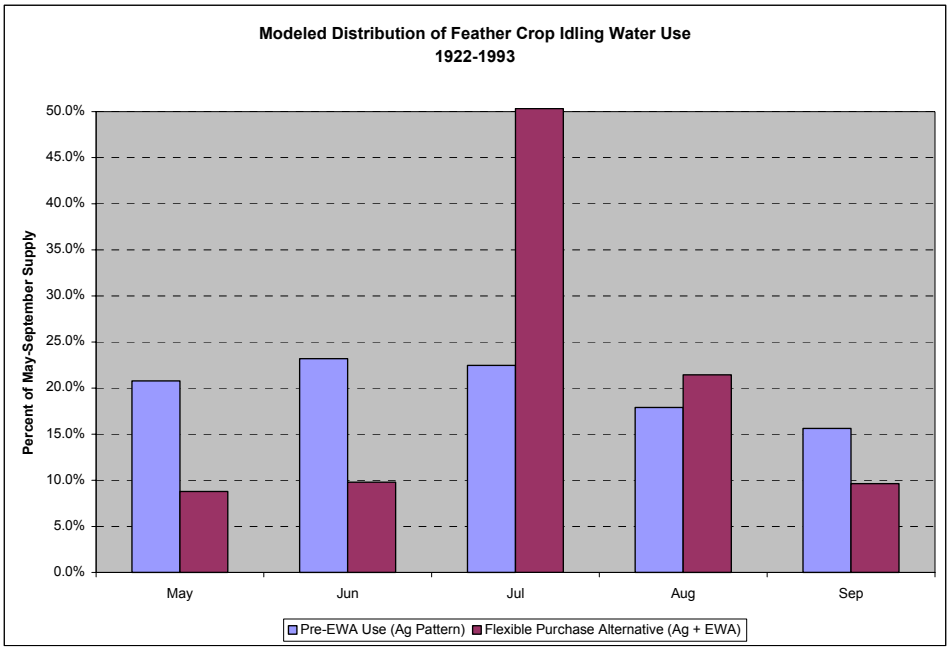

Figure 3
Modeled Distribution of Feather River Crop Idling Water Use (1922-1993)

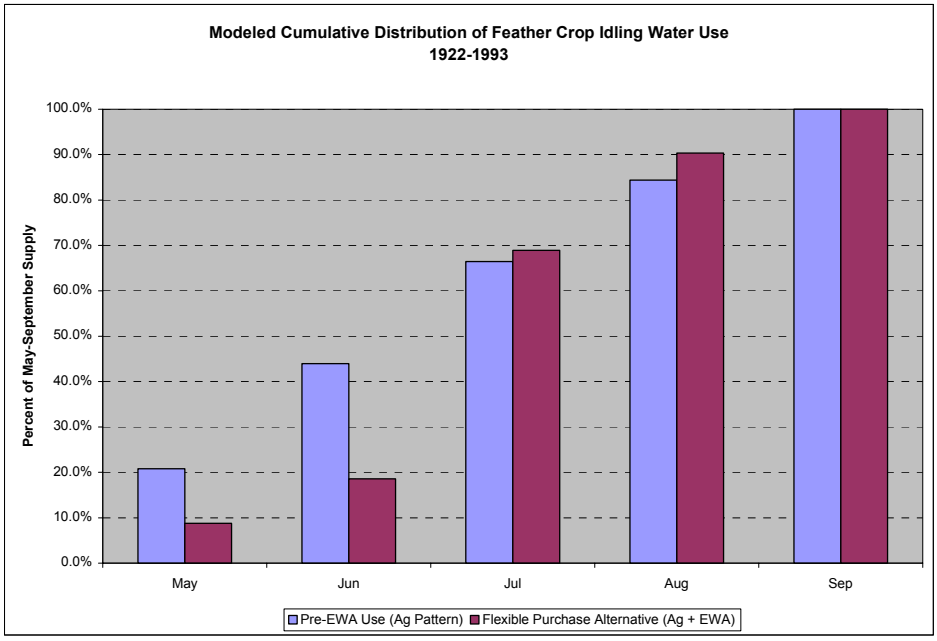

Figure 4
Modeled Cumulative Distribution of Feather River Crop Idling Water Use (1922-1993)

In order to not preclude any future operational flexibility by the SWP, it was determined that the EWA EIS/EIR should not suggest any change in the Baseline Condition during the July through September Project exports (no redistribution of SWP and CVP exports) presented in the CALSIM II simulation, which was provided by DWR. This determination is consistent with the full disclosure of potential effects of the proposed project and does not impose an obligation on the SWP to alter its own characterization of SWP operations. Also, throughout the analyses presented in the EIS/EIR, an assumption is made that presenting the worst-case condition is most defensible in identifying effects of the proposed project. In view of this conservative assumption, the effect of the Flexible Purchase Alternative on reservoir storage is identified as the comparison of the Flexible Purchase Alternative to the Baseline Condition. This assumption acknowledges worst-case conditions caused by the Flexible Purchase Alternative on reservoir fisheries and recreation.

2.1.3.5 Carriage Water

Exporting additional water from the Delta can adversely affect water quality in the Delta; therefore; the EWA routing procedure was developed to account for upstream river flows and Delta operations. Because additional Delta exports can have an adverse impact on water quality in the Delta, the routing procedure reflects the influence of increased exports on water quality. Carriage water is the term used for the amount of additional water assumed to be required as increased Delta inflow and outflow to maintain water quality standards in the Delta. Estimated carriage water costs associated with EWA exports range between 15 percent and 35 percent of the EWA share of Delta inflow. In application, if EWA exports were 150 TAF or less in a given month, EWA exports would be 85 percent (100 percent – 15 percent = 85 percent) of purchases, with the excess purchase going to Delta outflow. This percentage varied to 65 percent (100 percent – 35 percent = 65 percent) in months when the EWA export was greater than 400 TAF.

Carriage water is included in the EWA asset purchases and routed through the reservoir and river system in the same manner.

2.1.3.6 EWA Water Purchases.xls Post Processing Tool Output

The EWA Water Purchases.xls post processing tool provides the following output:

- Revised Shasta, Oroville, and Folsom storage;
- Revised flows for the Sacramento River at Keswick Reservoir, Feather River at Oroville Dam, and American River at Nimbus Reservoir;
- Revised flows for the Yuba River basin, Feather River basin, and Sacramento River basin; and
- Revised total Delta exports.

These outputs were then used in the EWA Routing.xls Tool (refer to Section 2.1.4) to produce the final "virtual" CALSIM II output database for use in the impact assessment.

2.1.4 EWA Routing.xls Post Processing Tool

This tool was developed to take the results of the CALSIM II Baseline Condition simulation and the EWA Water Purchases.xls tool (refer to Section 2.1.3), simulate or "route" the output (reservoir storage, releases, instream flows, etc.) through the Project system, and provide output (results) for a "virtual" CALSIM II output database.

The EWA Routing.xls tool has several basic functions:

- Final upstream of Delta Routing;
- Implementation of EWA fish actions in December through July;
- Final implementation of export shifting and additional EWA exports in July through September;
- Split of total Delta export into CVP and SWP exports (Tracy and Banks pumping plants);
- Full Delta routing; and
- "Virtual" CALSIM II output development.

2.1.4.1 Upstream from the Delta Routing

The EWA Routing.xls post processing tool involved determining and assigning the EWA assets to individual schematic nodes relative to the CALSIM II structure and calculating how the SWP and CVP system operations would change in response to a list of assumed EWA fish actions. Decisions were made regarding the location within a particular river basin (node) where individual fish actions would first influence system operations. Then, the initial results (reservoir storage, dam releases, and stream flows) from the CALSIM II benchmark study were recomputed from that location throughout the system upstream of the Delta. These assumptions are provided in Table 1. As shown in Table 1, the EWA asset actions that would take place within the Sacramento River Basin were split between two different nodes, 118 and 129.

Table 1 ***Assignment of EWA Asset Actions to CALSIM II Nodes***	
Description/EWA Asset Location	***CALSIM Schematic Node***
Shasta Reservoir Storage	4
Keswick Reservoir Release	6
Sacramento River Basin Assets (50 percent)	118
Sacramento River Basin Assets (50 percent)	129
Oroville Reservoir Storage	6
Oroville Reservoir Release	6
Yuba River Basin Assets	211
Feather River Basin Assets	223
Folsom Reservoir Storage	8
Nimbus Reservoir Release	9[a]
Lake McClure Storage	20
Lake McClure Release	20
[a] Includes flow modification upstream to Folsom (Node 8).	

2.1.4.2 Split of Total Delta Export Into CVP/SWP Exports

An intermediate step made by this tool evaluated and redistributed the total Delta exports relative to the CALSIM II Baseline Condition simulation results. During the summer months, if the total Delta export result obtained through post-processing was greater than the result in the CALSIM II Baseline Condition, the additional export amount was assigned first to the CVP Tracy Pumping Plant (up to a maximum of 4,600 cfs), then any remaining amount was assigned to the SWP Banks Pumping Plant. If the total Delta export result obtained through post-processing was less than the CALSIM II Baseline Condition simulation (e.g., winter/spring export curtailment months), then the baseline export values were recalculated. Reductions in exports were first applied to the SWP Banks Pumping Plant (maintaining a minimum diversion of 750 cfs), then any additional reductions were imposed at the CVP Tracy Pumping Plant.

2.1.4.3 Delta Routing

A final routing of the Delta was then done using Delta inflow values from the upstream routings and the final exports. Revised Delta Cross Channel flows, X2 location, and QWEST values were computed from the final routed values.

2.1.4.4 "Virtual" CALSIM II Output Creation

The EWA Routing.xls post processing tool was then used to create a "virtual" CALSIM II output database. This was accomplished by copying the CALSIM II baseline output database and saving the newly recomputed storages, flows, and exports from the spreadsheet into the database. This produces a CALSIM II output database with all revised values in it, which to the other post-processor tools appears to have come directly from a CALSIM II simulation. This allows other tools designed to work with CALSIM II simulation output to be used for output analysis and linkage to other models without modification.

2.1.5 Water Temperature Models

Reclamation has developed water temperature models for the Sacramento, Feather, and American Rivers. The models have both reservoir and river components to simulate water temperatures in five major reservoirs (Trinity, Whiskeytown, Shasta, Oroville, and Folsom); four downstream regulating reservoirs (Lewiston, Keswick, Thermalito, and Natoma); and three main river systems (Sacramento, Feather, and American).

These temperature models were designed to estimate water temperatures that would occur for conditions simulated by PROSIM, a Reclamation-developed operation model that is a predecessor to the CALSIM II model. They are used to assess changes in average monthly water temperature caused by changes in CVP/SWP operations. A spreadsheet post-processor tool was developed to allow use of CALSIM II-computed reservoir storage and stream flows to generate the required water temperature model inputs. There were no internal changes to any of the water temperature models.

The PROSIM operations model used a time period of 70 years from 1922 to 1991. Because the water temperature models were designed to operate using PROSIM results, and they operate on a calendar year, rather than on a water year basis, the period of record is 1922 to 1990 (69 years). Extension of the water temperature models to fully cover the CALSIM II time period of 1922 to 1993 (72 years) would have required extensive data development and model calibration effort and was not performed for this analysis.

Sections 2.1.5.1 and 2.1.5.2 provide additional detail regarding the reservoir and river components of the water temperature models, respectively. Additional details regarding Reclamation's water temperature models are well documented in the CVPIA *Draft Programmatic EIS (PEIS) Technical Appendix, Volume Nine*. These temperature models also are documented in the report titled: *U.S. Bureau of Reclamation Monthly Temperature Model Sacramento River Basin*, June 1990.

2.1.5.1 Reservoir Water Temperature Component

Reclamation's reservoir models simulate monthly water temperature profiles in five major reservoirs: Trinity, Whiskeytown, Shasta, Oroville, and Folsom. Vertical water temperature profile in a reservoir is simulated in one dimension using monthly storage, inflow and outflow water temperature and flow rate, evaporation, precipitation, solar radiation, and average air temperature. The models also compute the water temperatures of dam releases. Release water temperature control measures in reservoirs, such as the penstock shutters in Folsom Reservoir, the temperature control device in Lake Shasta, and the temperature curtains in Whiskeytown Reservoir are incorporated into the models.

Reservoir inflow, outflow, and end-of-month storage content as calculated by CALSIM II are input to the reservoir water temperature models. Additional input data include meteorological information and monthly water temperature targets that are used by the model to select the level from which reservoir releases are drawn. Model output includes water temperature at each level in the reservoir as well as temperature of the reservoir release. The reservoir release temperature is then used in the downstream river water temperature model, as described in the next section.

2.1.5.2 River Water Temperature Component

Reclamation's river water temperature models utilize the calculated temperatures of reservoir release, much of the same meteorological data used in the reservoir models (described in Section 2.1.5.1), and CALSIM II output on river flow rates, gains and diversions. Mean monthly water temperatures are calculated at multiple locations on the Sacramento, Feather, and American Rivers.

Release rate and water temperature of regulating reservoir storage serve as the boundary conditions for the river water temperature model. The river temperature model computes

water temperatures at 52 locations on the Sacramento River from Keswick Dam to Freeport, and at multiple locations on the Feather and American Rivers. The river temperature model also calculates water temperature within Lewiston, Keswick, Thermalito, and Natoma Reservoirs. This model is used to simulate water temperatures in these reservoirs because they are relatively small bodies of water with short residence times; thereby, on a monthly basis, the reservoirs act as if they have physical characteristics approximating those of riverine environments.

2.1.5.3 Automated Temperature Selection Procedure

The Folsom Reservoir and lower American River water temperature model components are utilized in an iterative manner referred to as the Automated Temperature Selection Procedure (ATSP). This procedure operates the reservoir and river water temperature models with the objective of achieving monthly target temperatures in the lower American River at Watt Avenue. The target water temperatures have been set by qualified fisheries biologists who have determined a range of water temperatures that are the most biologically favorable to the fish species that are present in the river, at any given time of year. Targets are achieved through a choice of reservoir levels from which the release is drawn. This modeling procedure is conducted for the purpose of allowing the most optimal utilization of the available coldwater pool in Folsom Lake and to ensure that the species-specific needs of anadromous fish in the river are met over the course of the entire year.

2.1.5.4 Folsom Reservoir Model Code Modifications

The Folsom Reservoir water temperature model component was modified to simulate a Temperature Control Device (TCD) for the Folsom Dam Pumping Plant. The TCD has been authorized by Congress and is expected to be in place in the next few years. The TCD was incorporated into the model by defining numerous levels from which Folsom Dam diversions could occur. The TCD is operated to maximize the use of warm water; thus, the diversion level is set as close to 25 feet below the reservoir water surface as possible.

2.1.6 Salmon Mortality Models

Water temperatures calculated for specific reaches of the Sacramento and American Rivers are used in Reclamation's Chinook salmon mortality models to estimate annual percentage mortality of early-lifestage Chinook salmon. Reclamation's Chinook salmon mortality models produce a single estimate of early life stage Chinook salmon mortality for each year of the simulation. This estimate consolidates calculations of salmon mortality for three separate early-life stages (1) pre-spawned eggs; (2) fertilized eggs; and (3) pre-emergent fry. For the Sacramento River, the model computes mortality for each of the four Chinook salmon runs: fall, late-fall, winter, and spring. For the American River, the model produces estimates of fall-run Chinook salmon mortality only. The mortality estimates are based on output temperatures from Reclamation's water temperature models. Temperature units (TUs), defined as the difference between river temperatures and 32°F, are accounted for on a daily basis by the mortality model, and are used to track life-stage development. For example, incubating eggs exposed to 42°F water for one day would experience 10 TUs. Eggs are assumed to hatch upon exposure to 750 TUs following fertilization. Similarly, the salmon mortality model assumes that fry emerge from the gravel after being exposed to 750 TUs following egg hatching into the pre-emergent fry stage.

2.1.7 Graphic and Tabular Analysis of Environmental Resources (GATAER) Tool

The GATAER tool produces figures and tables for the analysis of output from CALSIM II, the water temperature models, salmon mortality models, and other post-processing applications. Data is loaded from these models into a DSS database, which is then used as input to a series of spreadsheets, which generate the figures and tables for environmental resource analyses. The figures and tables generated for the evaluations of specific resource areas are included in Appendix H of the EWA EIS/EIR.

2.1.8 Delta Simulation Model II (DSM2)

DSM2 is the Delta hydrodynamic and salinity model currently in use by DWR. The model is capable of simulating physical conditions in riverine systems and estuaries, and the effects of land-based processes (agricultural runoff and consumptive use). These wide-ranging capabilities make it a valuable tool for analyzing the potential effects of proposed EWA actions in the Delta.

The hydrodynamic module simulates the channel flows, velocities, and water surface elevations in the Bay-Delta estuary. The water movement information developed by the hydrodynamic module is then used as input into the other two modules (water quality and particle-tracking), which can be used to determine the movement of constituents. The water quality module calculates the changes in water quality (primarily salinity) resulting from different source water qualities and from the mixing caused by water movement throughout the system. The particle-tracking module is used to evaluate mass transport processes.

DSM2 can calculate stages, flows, velocities, and many mass transport processes, including salts, multiple non-conservative constituents, and water temperature, and individual particles. For the EWA EIS/EIR, results from the EWA Routing.xls post processing tool (Section 2.1.4) provided input for the calculation of Delta export salinity and water level changes caused by the EWA actions.

Additional information on DSM2 model and documentation is publicly available from the DWR, Bay-Delta Office, Modeling Support Branch web site. A detailed discussion of the model and its assumptions are contained at this location: http://modeling.water.ca.gov/delta/models/dsm2/documentation.html.

2.1.9 Application of Hydrologic Modeling Output

The models and post-processing tools used in this analysis have been developed for comparative planning purposes, rather than for predicting actual reservoir or river conditions at specific locations at specific times. The 72-year and 69-year periods of record for CALSIM II and water temperature modeling, respectively, provide an index of the kinds of changes that would be expected to occur with implementation of a specified set of operational conditions. Reservoir storage, river flows, water temperature, and salmon mortality output for the period modeled should not be interpreted or used as definitive absolutes depicting actual conditions that will occur in the future. Rather, output for the Flexible Purchase Alternative can be compared to output for the Baseline Condition to determine:

- Whether reservoir storage or river flows and water temperatures would change with implementation of the alternative;

- The months in which potential reservoir storage and river flow and water temperatures changes could occur; and

- A relative index of the magnitude of change that could occur during specific months of particular water year types, and whether the relative magnitude would result in impacts to water quality, fish, or power resources within the area studied.

The models used, although mathematically precise, should be viewed as having reasonable detection limits. Establishing reasonable detection limits is useful to those using the modeling output for impact assessment purposes, and prevents making inferences beyond the capabilities of the models and beyond an ability to actually measure changes. Although data from the models are reported to the nearest 1) 1,000 acre-feet in reservoir storage; 2) foot in water surface elevation; 3) cubic foot per second in river flow; 4) 0.1 ^{o}F in water temperature; and 5) tenth of a percent in salmon mortality, these values were rounded when interpreting differences for a given parameter between two modeling simulations. For example, two simulations having river flows at a given location within one percent of each other were considered to be essentially equivalent (represent no measurable change). Because the models provide reservoir storage data on a monthly time-step, measurable differences in reservoir storage were evaluated on a similar basis. Similar rounding of modeled output was performed for other output parameters as well in order to assure the reasonableness of the impact assessments.

In-situ temperature loggers were used to collect water temperature data used for the model. These loggers typically have a precision of +/-0.36 ^{o}F, yielding a potential total error of 0.72 ^{o}F (Sacramento River Temperature Modeling Project 1997). Therefore, modeled differences in water temperature of 0.36 ^{o}F or less could not be consistently detected in the river by actual monitoring of water temperatures. In addition, as mentioned above, output from Reclamation's water temperature models provides a relative index of water temperatures under the various operational conditions modeled. Output values indicate whether the water temperatures would be expected to increase, remain unchanged, or decrease, and provide insight regarding the relative magnitude of potential changes under one operational condition compared to another. For the purposes of the EWA impact assessment, modeled water temperature changes that were within 0.3 ^{o}F between modeled simulations were considered to be essentially equivalent. A level of detection of measurable change of 0.3 ^{o}F was used because 1) model output is reported to 0.1 ^{o}F; 2) rounding the level of error associated with in-situ temperature loggers used for model temperature data up to 0.4 ^{o}F would eliminate the possibility of detecting measurable change between 0.36 ^{o}F and 0.4 ^{o}F; and 3) rounding the level of detection down to 0.3 ^{o}F is the more conservative approach in detecting a change in temperature between the modeling results. Temperature differences between modeling results of more than 0.3 ^{o}F were assessed for their biological significance. This approach is considered very rigorous, because it utilizes a more conservative threshold of detection for potential water temperature changes than used in other fisheries impact assessments. For example, USFWS and Reclamation, in the Trinity River Mainstem Fishery Restoration Draft EIS/EIR (USFWS *et al.* 1999), used a change in long-term average water temperature of 0.5 ^{o}F as a threshold of significance, and the Central Valley Regional Water Quality Control Board generally uses a change of 1.0 ^{o}F as a threshold of significance.

2.2 Model Simulations and Assumptions/Impact Analysis Approach

Modeling simulations were developed to evaluate potential environmental effects of the Flexible Purchase Alternative. Because there are no other known foreseeable State or private actions that would be implemented during the period of time defined by the EWA Program (2000-2007), a separate cumulative modeling run was not performed. Conditions under the cumulative condition would be the same as those that were modeled under the Flexible Purchase Alternative.

The development of the modeling simulations and consideration of available information or data resulted in the development of two different approaches to model and evaluate Upstream from the Delta Region and Delta Region effects of the Flexible Purchase Alternative on water quality, fisheries, and power resources. These two approaches are described in the following sections.

2.2.1 Upstream from the Delta Region

The hydrologic analysis performed for the Upstream from the Delta Region includes the CVP and SWP facilities on the Sacramento River (Shasta Reservoir, Keswick Reservoir), Feather River (Lake Oroville), and American River (Folsom Reservoir). The Delta Region analysis is evaluated with a separate set of simulations and assumptions as described in Section 2.2.2.

2.2.1.1 Upstream from the Delta Region - Baseline Condition Simulation

The CALSIM II benchmark study (BST_2001D10A_ANNBENCHMARK_1_2_B2_7-23-2002) was used as the basis for all hydrologic modeling presented in the EWA EIS/EIR. As described earlier, the CALSIM II simulation utilized the wrapper representing D-1485 through CVPIA b(2) regulatory constraints.

CALSIM II documentation is publicly available from the DWR, Bay-Delta Office, Modeling Support Branch web site. A detailed discussion of the model and its assumptions are contained in the document entitled "BST_2020D09D_ANNBENCHMARK_2_2, Benchmark Studies Assumptions and Appendices." This document includes the assumptions for the CALSIM II 2001 benchmark study (BST_2001D10A) identified above.

The Baseline Condition simulation represents the hydrologic conditions within the CVP/SWP system prior to CALFED Record of Decision (ROD) and implementation of the EWA Program (prior to 2001). As discussed in Chapter 2 of the EWA EIS/EIR, the No Action/No Project Alternative conditions are represented by the Baseline Condition. The simulation includes surface water diversion and operation practices and policies (such as minimum instream flows, flood control, and Delta water quality standards) of the CVP/SWP and assumptions associated with accretion and depletions from the system that incorporate the exercise of water rights by non-CVP/SWP users.

The modeling assumptions incorporated into the CALSIM II benchmark study and utilized in further development of the Baseline Condition simulation are summarized in Table 2. More detailed descriptions of these assumptions follow the table.

Table 2 ***EWA Modeling Assumptions Included in the CALSIM II Benchmark Study***	
Parameter	***Benchmark Study Assumption***
PERIOD OF RECORD	1922-1993 (72 years)
HYDROLOGY	
Level of Land Use	2001 Level, DWR Bulletin 160-98[1] 2020
DEMANDS	
North of Delta (excluding American River)

SWP (FRSA)	Land Use based, limited by Full Contract
non-Project	Land Use based
CVP Refuges	Firm Level 2
American River Basin Water Rights CVP	 2001[2] 2001[2]
San Joaquin River Basin Friant Unit Lower Basin Stanislaus River Basin	 Regression of historical Fixed annual demands New Melones Interim Operations Plan
South of Delta	
CVP	Full Contract
Contra Costa Water District	140 TAF/YR[3]
SWP (w/ North Bay Aqueduct)	3.0-4.1 MAF/YR
SWP Article 21 Demand	MWDSC up to 50 TAF/month, Dec-Mar, others up to 84 TAF/month
FACILITIES	**Existing Facilities (2001)**
RESERVOIR REFILL CRITERIA	Annual refill occurs
REGULATORY STANDARDS	
Trinity River	
Minimum Flow below Lewiston Dam	Trinity EIS Preferred Alternative (369-815 TAF/YR)
Trinity Reservoir End-of-September Minimum Storage	Trinity EIS Preferred Alternative (600 TAF as able)
Clear Creek	
Minimum Flow below Whiskeytown Dam	Downstream water rights, 1963 USBR Proposal to USFWS and NPS, and USFWS discretionary use of CVPIA 3406(b)(2)
Upper Sacramento River	
Shasta Lake End-of-September Minimum Storage	SWRCB WR 1993 Winter-run Biological Opinion (1900 TAF)
Minimum Flow below Keswick Dam	Flows for SWRCB WR 90-5 and 1993 Winter-run Biological Opinion temperature control, and USFWS discretionary use of CVPIA 3406(b)(2)
Feather River	
Minimum Flow below Thermalito Diversion Dam	1983 DWR, DFG Agreement; (600 cfs)
Minimum Flow below Thermalito Afterbay outlet	1983 DWR, DFG Agreement; (1000 – 1700 cfs)
Yuba River	
Minimum Flow below Englebright Dam (as measured at the Marysville and Smartville gauging stations)	2001 SWRCB decision D-1644; Interim (100-1500)
American River	
Minimum Flow below Nimbus Dam	SWRCB D-893 (see accompanying Operations Criteria), and USFWS discretionary use of CVPIA 3406(b)(2)
Minimum Flow at H Street Bridge	SWRCB D-893
Lower Sacramento River	
Minimum Flow near Rio Vista	SWRCB D-1641
Mokelumne River	
Minimum Flow below Camanche Dam	FERC 2916-029, 1996 (Joint Settlement Agreement); (100 – 325 cfs)
Minimum Flow below Woodbridge Diversion Dam	FERC 2916-029, 1996 (Joint Settlement Agreement); (25 – 300 cfs)
Stanislaus River	
Minimum Flow below Goodwin Dam	1987 USBR, DFG agreement, and USFWS discretionary use of CVPIA 3406(b)(2)
Minimum Dissolved Oxygen	SWRCB D-1422

Table 2 ***EWA Modeling Assumptions Included in the CALSIM II Benchmark Study***	
Parameter	***Benchmark Study Assumption***
Merced River	
Minimum Flow below Crocker-Huffman Diversion Dam	Davis-Grunsky (180 – 220 cfs, Nov – Mar), and Cowell Agreement;
Minimum Flow at Shaffer Bridge	FERC 2179; (25 – 100 cfs)
Tuolumne River	
Minimum Flow at Lagrange Bridge	FERC 2299-024, 1995 (Settlement Agreement) (94 – 301 TAF/YR)
San Joaquin River	
Maximum Salinity near Vernalis	SWRCB D-1641
Minimum Flow near Vernalis	SWRCB D-1641, and Vernalis Adaptive Management Program per San Joaquin River Agreement
Delta Outflow Index (Flow and Salinity)	
Delta Cross Channel Gate Operation	SWRCB D-1641
Delta Exports	SWRCB D-1641, USFWS discretionary use of CVPIA 3406(b)(2), and CALFED Fisheries Agencies discretionary use of EWA
OPERATIONS CRITERIA	
Upper Sacramento River	
Flow Objective for Navigation (Wilkins Slough)	Discretionary 3,500 – 5,000 cfs based on Lake Shasta storage condition
American River	
Folsom Dam Flood Control	SAFCA, Interim-Reoperation of Folsom Dam, Variable 400/670 (without outlet modifications)
Flow below Nimbus Dam	Discretionary operations criteria corresponding to SWRCB D-893 required minimum flow
Sacramento Water Forum Mitigation Water	None
Stanislaus River	
Flow below Goodwin Dam	1997 New Melones Interim Operations Plan
San Joaquin River	
Flow near Vernalis	San Joaquin River Agreement in support of the Vernalis Adaptive Management Program
System-wide	
CVP Water Allocation	
CVP Settlement and Exchange	100% (75% in Shasta Critical years)
CVP Refuges	100% (75% in Shasta Critical years)
CVP Agriculture	100% - 0% based on supply (reduced by 3406(b)(2) allocation)
CVP Municipal & Industrial	100% - 50% based on supply (reduced by 3406(b)(2) allocation)
SWP Water Allocation	
North of Delta (FRSA)	Contract specific
South of Delta	Based on supply; Monterey Agreement
CVP/SWP Coordinated Operations	
Sharing of Responsibility for In-Basin-Use	1986 Coordinated Operations Agreement
Sharing of Surplus Flows	1986 Coordinated Operations Agreement
Sharing of Restricted Export Capacity	Equal sharing of export capacity under SWRCB D-1641; use of CVPIA 3406(b)(2) only restricts CVP exports; EWA use restricts CVP and/or SWP as directed by CALFED Fisheries Agencies
CVPIA 3406(b)(2)	
Allocation	800 TAF/YR (600 TAF/YR in Shasta Critical years)
Actions	1995 WQCP (non-discretionary), Fish flow objectives (Oct-Jan), CVP export reduction (Dec-Jan), VAMP (Apr 15- May 16) CVP export restriction, 3000 cfs CVP export limit in May and June (D1485 Striped Bass continuation), Post (May 16-31) VAMP CVP export restriction, Ramping of CVP export (Jun), Pre (Apr 1-15) VAMP CVP export restriction, CVP export reduction (Feb-Mar), Upstream Releases (Feb-Sep)

Table 2 ***EWA Modeling Assumptions Included in the CALSIM II Benchmark Study***	
Parameter	***Benchmark Study Assumption***
Accounting Adjustments	Per February 2002 Interior Decision, no limit on responsibility for non-discretionary D1641 requirements, no Reset with the Storage metric and no Offset with the Release and Export metrics
1 2001 Level of Development defined by linearly interpolated values from the 1995 Level of Development and 2020 Level of Development from DWR Bulletin 160-98. 1 1998 Level Demands defined in Sacramento Water Forum's EIR with a few updated entries. 2 Delta diversions include operations of Los Vaqueros Reservoir operations.	

Period of Record

The period of record used in the hydrologic modeling (CALSIM II) extends from October 1922 through September 1993 (72 years). The period of record used for water temperature modeling and the associated simulations for early lifestage Chinook salmon mortality extends from 1922 through 1990 (69 years). These periods are considered representative of the natural variation in climate and hydrology experienced in the Central Valley during recent times, and include periods of extended drought, high precipitation and runoff, and variations in-between.

Hydrology/Level of Development

The hydrology used is based on DWR Bulletin 160-98. The assumptions used for land use result from aggregation of historical survey and projected data developed for the California Water Plan Update (Bulletin 160). The Baseline Condition uses a 2001 level of land use, estimated by DWR as a linear interpolation between 1995 and 2020 land uses. Because the timeframe for EWA is relatively short (2001 to 2007) compared to the future condition demands (2020) that are used by the model, there is little variation between 2001 demands and projected 2007 demands. As a result, the hydrology used by CALSIM II for the future condition (2007 system demands) is consistent with 2001 land use and development projections.

Demands

The following sections describe how CALSIM II represents water demands within the system represented by the model.

CALSIM II classifies demands for water diversions as CVP project, SWP project, or non-project demands. CVP project demands are separated into four classes based on contract type: agricultural, municipal and industrial (M&I), Settlement and Exchange contractors, and refuges. Demands also are designated by geographic location: Sacramento River Basin, Feather River Service Area (FRSA), American River Basin, San Joaquin River Basin, Delta, and south of the Delta. Demands may be represented as a time series, varying by month and year, or more simply as twelve repeating monthly values. CVP project demands are modeled based on the conditions that apply to the contract type. SWP demands are simulated as defined and referred to by DWR's Office of Planning.

Demands in the Sacramento River Basin, including the Feather River and American River basins, and the Delta are determined based on land use and vary by month and year according to hydrologic conditions. Demands in the East Side Streams area and San Joaquin River Basin are set to fixed values each year. CVP and SWP demands south of the Delta are based on contract amounts, CVP demands are constant each year, and SWP demands vary depending on a wetness index.

Demands Upstream from the Delta (Excluding the American River Basin)

Demands in the Sacramento River Basin, including the Feather River, are determined based on land use for each Depletion Study Area (DSA). The land use acreage used to develop water demands is based on the indicated LOD. A consumptive use model is used to estimate demands for each DSA.

Demands within each DSA must be disaggregated into CVP and/or SWP project and non-project demands. Project demands are subject to reduced water allocations based on contracts with the CVP and SWP, while non-project demands are satisfied from sources other than the CVP and SWP project facilities. Non-project demands can be associated with senior riparian water rights, groundwater pumping, or private storage projects. Releases from the CVP and SWP system are increased to satisfy project demands, but no additional releases are made to satisfy non-project demands.

Demands in the Sacramento River Basin are divided into project/non-project in CALSIM II using a GIS snapshot of the crop and urban acreage (based on county surveys done in the 1990's). CVP contracts in the Sacramento Valley, excluding the American River Basin, consist of Settlement contracts (approximately 2.2 million acre feet [MAF]) and agricultural service contracts (approximately 460 TAF). The FRSA demands are the only SWP demands north of the Delta. These users are entitled to approximately 1.0 MAF per year (MAF/Yr) diversion from the Feather River. Although diversion requirements for contractors north of the Delta are determined using the consumptive use model based on land use, CALSIM II limits their deliveries to the maximum amount under their contract.

CVP Refuges: Firm Level 2

Firm Level 2, current annual average, national wildlife refuge (NWR) water demands are used for the Sacramento, San Joaquin, and Tulare basins. The refuge demands are consistent with the Reclamation Report On Refuge Water Supply Investigations, Central Valley Hydrologic Basin, California - March 1989, with the exception of East Bear Creek Unit data that is from Reclamation's Draft Refuge Water Supply - Long Term Water Supply Agreements, San Joaquin River Basin - November 2000 (Table 1-1). The refuge water demand quantities presented in Table 3 represent the amount of water required to meet refuge demands at the refuge boundaries (firm) and include conveyance losses.

American River Basin

The Water Forum Agreement provides for surface diversion reductions from the American River in "dry" through "driest" years. "Driest" year diversions are no greater than the "1995 Baseline" defined by the Water Forum participants. A "dry" year is defined as a year in which the forecasted Folsom Unimpaired Inflow for March through November (modeled as March 1 through September 30 plus 60 TAF) is less than 950 TAF. A "driest" year is defined as a year in which the forecasted Folsom Unimpaired Inflow for March through November is less than 400 TAF. A summary of demands for the American River Basin is presented in Table 4.

Table 3 ***CVP Refuge Water Demand - Firm Level 2***			
Location	***Demand***	***Location***	***Demand***

Total 2020 Level	15,000	180,850	400,850	596,700	450,100	146,600

San Joaquin River Basin

Demands in the San Joaquin River Basin generally are set to fixed annual amounts rather than based on land use and hydrologic conditions as with the Sacramento Valley demands presented above. The operation of the Friant Unit is extracted from a SANJASM model simulation and is not operated in CALSIM II. Table 5 presents average annual diversions and fixed annual demands for projects in the San Joaquin River Basin. These demands are incorporated into the CALSIM II benchmark study used for the EWA EIS/EIR modeling.

Demands South of the Delta

CVP and SWP demands south of the Delta are based on contract amounts; SWP demands vary depending on a wetness index.

CVP South of the Delta

CVP demands south of the Delta include agricultural and M&I needs served from the San Luis Reservoir and San Felipe Unit, the Cross Valley Canal, the Delta-Mendota Canal (DMC) and Mendota Pool. CVP demands south of the Delta are always set to contract amount and do not vary based on hydrologic conditions. These demands also include Exchange Contractors, refuge water supplies and operational losses. CVP demands are aggregated based on contract type and the following geographic locations: Upper DMC, Lower DMC, Mendota Pool, San Felipe Unit, and California Aqueduct.

Table 5 ***San Joaquin River Basin Demand Assumptions***	
Location	***Demand (TAF)***
Friant-Kern Canal*	1,100
Madera Canal to Madera ID*	145
Madera Canal to Chowchilla ID*	98

Chowchilla **	293
Merced ID **	620
Turlock ID **	733
Modesto ID **	417
Tri-dams**	574
*Annual average delivery **Fixed annual demand ID – Irrigation District	

Monthly demand patterns are determined for Exchange, M&I, and agricultural contractors based on recent historical CVP deliveries. Table 6 contains a summary of the total CVP demands south of the Delta, not including refuge demands.

Table 6 ***CVP South-of-Delta Contract-Based Demands***	
Contract Type	***Demand Amount (AF)***
Water Right	40,813
Project Agricultural	1,824,758
Exchange	840,000
M&I	154,150
Losses	183,700
Total	3,043,421

SWP South of the Delta

Twenty-nine agencies have contracts for a long-term water supply from the SWP totaling about 4.2 MAF annually, of which about 4.1 MAF are for contracting agencies with service areas south of the Delta. About 70 percent of this amount is the contract entitlement for urban users and the remaining 30 percent is for agricultural users.

Demands are set in accordance with the Monterey Agreement. They are calculated from the 1996 Table A entitlements. Aqueduct deliveries to San Joaquin Valley agricultural contractors are reduced in wetter years using a wetness index developed from annual Kern River inflows to Lake Isabella. Deliveries to the Metropolitan Water District of Southern California (MWDSC) are reduced in wetter years using the 10-station, two-year average precipitation index or based upon MWDSC integrated operations with Eastside Reservoir in future scenarios.

When available, Article 21 water is delivered to SWP south-of-Delta contractors in accordance with the Monterey Agreement. Article 21 water results from direct diversions from Banks Pumping Plant; it is not stored in San Luis Reservoir for later delivery to contractors. A contractor may accept Article 21 water in addition to its monthly scheduled entitlement water. Article 21 water deliveries do not impact Table A entitlement water allocations. If demand for Article 21 water is greater than supply in any month, the supply is allocated in proportion to the entitlements of those contractors requesting Article 21 water.

CVP and SWP Facilities and Operations

The major water storage and conveyance facilities included in CALSIM II, are identified in Table 7 and Table 8, respectively. Specific criteria have been defined for each of these facilities for incorporation into the model. Criteria include physical characteristics (storage and conveyance capacity), evaporation and loss estimates, regulatory and operational requirements, and incorporation of each facility into the overall system.

Table 7
Major Central Valley Project and State Water Project Storage Facilities Included in CALSIM II

Storage Facility	*Gross Storage Capacity (TAF)*

Delta Mendota Canal upstream of Delta Mendota Pool	3200

Regulatory Standards

The following sections describe the major CVP and SWP operations and regulatory constraints that are specific to, and occur within, the various regional river basins that are evaluated as part of the modeling applications and hydrologic analyses. These operational and regulatory conditions influence several aspects of water management and availability of water supplies (e.g., conveyance capacities) for the Baseline Condition.

Various laws and regulatory decisions provide for protection of environmental conditions. These protections include minimum instream flow requirements, minimum reservoir storage levels, and protection of the Delta against excessive salinity. Specifics regarding these requirements, including references to the regulatory documentation, are provided in the individual resource chapters of the EWA EIS/EIR. As an overview, Table 9 summarizes the locations and applicable regulatory conditions that are either incorporated directly into the model, pre- or post-processing applications, or used as evaluation criteria in interpreting the modeling results.

Table 9
Regulatory Standards and Modeling Applications

Location	***Regulatory Standard***	***Modeling Application***
Trinity River/Reservoir	Minimum instream flow requirements Minimum end-of-year reservoir storage	Both incorporated into CALSIM II
Clear Creek	Minimum instream flow requirements below Whiskeytown Reservoir	Incorporated into CALSIM II
Upper Sacramento River	Minimum end-of-year storage in Shasta Lake	Objective evaluated in interpretation of CALSIM II results
	Minimum instream flow requirements below Keswick Dam	Incorporated into CALSIM II
	Navigation flow requirement upstream of City of Sacramento (at Wilkins Slough-navigation control point)	Incorporated into CALSIM II
Feather River	Minimum instream flow requirements	Incorporated into CALSIM II
Yuba River*	Minimum instream flow requirements	Incorporated into CALSIM II
Lower American River	Minimum instream flow requirements (1) below Nimbus Dam and (2) for the reach from Nimbus Dam to the confluence with the Sacramento River	Incorporated into CALSIM II
Lower Sacramento River	Minimum instream flow requirements at (1) Freeport and (2) Rio Vista	Incorporated into CALSIM II
Mokelumne River*	Minimum release rates from Camanche Reservoir	Incorporated into CALSIM II
Stanislaus River	Minimum instream flows below Goodwin Dam	Incorporated into CALSIM II
Tuolumne River	Minimum instream flow requirements at LaGrange Bridge	Incorporated into CALSIM II
San Joaquin River	Minimum instream flow requirements at Vernalis	Incorporated into CALSIM II
Delta	Maximum salinity, minimum dissolved oxygen, minimum outflow, and maximum export	Incorporated into CALSIM II

* Regulatory standards for these rivers are included in pre-processed data. This output is then incorporated into CALSIM II as a single data point.

CVP and SWP Operation

The respective operations of the CVP and SWP are coordinated to manage stream flows in many Central Valley streams and the Delta. Many factors are considered in the operation of the CVP and SWP facilities. Releases from CVP and SWP reservoirs must be sufficient to achieve downstream environmental conditions; such as instream flow, water quality, and water

temperature objectives as required at various locations within the river systems and in the Delta.

Operators must meet environmental obligations and also attempt to meet competing demands for Project water. Considerations in determining the required releases include the diversions of CVP and SWP water contractors from the river system, diversions by non-CVP and SWP entities, the contribution of flow into the river system from streams not controlled by the CVP and SWP, the contribution of return flows into the system from agricultural drains and wastewater treatment plants, and operations of other projects.

Sacramento-San Joaquin Delta

Instream flow objectives for the Delta are governed by State and Federal laws and regulations established for the protection of fishery and aquatic resources. Requirements are defined in the following:

- SWRCB Water Quality Control Plan for the San Francisco Bay/Sacramento-San Joaquin Delta Estuary (Bay-Delta Plan) (SWRCB 1995);
- National Oceanic and Atmospheric Administration, National Marine Fisheries Service (NOAA Fisheries) Winter-run Chinook Salmon Biological Opinion (NMFS 1995); and
- U.S. Fish and Wildlife Service (USFWS) Delta Smelt and Sacramento Splittail Biological Opinion (USFWS 1995).

The Bay-Delta Plan establishes measures to protect the beneficial uses of the Bay-Delta and includes objectives that influence the operations of the CVP and SWP. Some of these objectives (specific flow, water temperature, reservoir storage, and diversion requirements) in the Delta were developed through consultation with NOAA Fisheries for the Winter-run Chinook Salmon Biological Opinion. Reclamation operates the CVP in accordance with the terms and conditions in all the various water rights orders, permits, and licenses for the project. Reclamation and DWR both operate their respective facilities in a manner that is consistent with applicable Biological Opinions.

Sacramento River

In addition to the State and Federal laws and regulations governing instream flow objectives in the Delta, the following requirements have been established to protect the fisheries and aquatic resources in the Sacramento River:

- SWRCB water rights terms and conditions for instream flow and flow fluctuation for Keswick Dam and Red Bluff Diversion Dam (SWRCB 1995);
- Central Valley Regional Water Quality Control Board (RWQCB) Basin Plan Water Quality Objectives for temperature and water quality constituents established to maintain fishery uses as approved by the SWRCB under the Federal Clean Water Act (RWQCB 1998);
- Iron Mountain Mine Interim Superfund Site ROD and the Memorandum of Understanding (MOU) with Reclamation concerning dilution manipulation of Spring

Creek Debris Dam releases using Shasta Dam releases (EPA 1997; Reclamation *et al*. 1980);

- NOAA Fisheries Winter-run Chinook Salmon Biological Opinion (NMFS 1995);
- NOAA Fisheries Spring-run Chinook Salmon and Central Valley Steelhead Biological Opinion on interim operations of the CVP and SWP (NMFS 2001); and
- ROD for the Trinity River Restoration Project that contributes to the timing and amount of flow releases at Keswick Dam (USFWS 2000).

Feather River

DWR operates the Oroville Facilities to comply with current Federal Energy Regulatory Commission (FERC) license requirements and other environmental protection measures. These measures include the NOAA Fisheries, NMFS Spring-run Chinook Salmon and Central Valley Steelhead Biological Opinion on interim operations of the CVP and SWP. Instream flows and water quality are managed according to the terms of a 1983 agreement between DWR and the California Department of Fish and Game (CDFG). This agreement establishes criteria for flow and water temperatures in the low-flow channel (Feather River between the Fish Barrier Dam and Thermalito Afterbay outlet) of the Feather River and the reach of the Feather River below the Thermalito Afterbay outlet to the confluence with the Sacramento River. Water temperatures also are regulated under a 1999 agreement between the licensee (DWR) and Joint Water Districts in an effort to assist farmers in achieving agricultural production objectives that rely on warm water. The FERC license requires that DWR attempt to release water that is as close as possible to the maximum allowable under the 1983 DWR-CDFG agreement.

Yuba River

The Yuba River is subject to instream flow requirements according to SWRCB Decision 1644 (D-1644), which came into effect on March 1, 2001. The intent of these requirements is to provide protection for fishery resources and other issues relating to water use and diversion activities in the lower Yuba River (the Yuba River below Englebright Dam). D-1644 specifies new minimum flow requirements (interim and long-term) and flow fluctuation criteria for the lower Yuba River. Because several of the conditions specific to D-1644 are currently being contested and undergoing litigation, they may be subject to revision; SWRCB is soon expected to make a decision soon. Until those proceedings are finalized, the conditions described in D-1644 apply and are incorporated into the hydrologic modeling assumptions.

Additionally, Yuba River operations must comply with the conditions established in the Yuba County Water Agency Act, water rights permits and licenses administered by the SWRCB, FERC License #2246 for the Yuba River Development Project, FERC 1993 License to Pacific Gas and Electric Company (PG&E) for continued operation at the Narrows I Power House, Section 7 of the Flood Control Act of 1944 (at New Bullards Bar Dam and Reservoir), and the 1966 Power Purchase Contract between Yuba County Water Agency (YCWA) and PG&E (Bookman-Edmonston 2000).

Lower American River

Reclamation operates Folsom Reservoir and Dam to comply with the objectives and environmental obligations of the Bay-Delta Plan, NOAA Fisheries Winter-run Chinook Salmon

Biological Opinion, NOAA Fisheries Spring-run Chinook Salmon and Central Valley Steelhead Biological Opinion on interim operations of the CVP and SWP, USFWS Delta Smelt Biological Opinion; USFWS Splittail Biological Opinion, and the management of CVPIA (b)(2) water. Reclamation also operates Folsom Dam according to year round flow requirements established by SWRCB Decision 893 (D-893). When possible, CVP operations also try to meet the Anadromous Fisheries Restoration Program (AFRP) flow objective for the lower American River as set forth in the November 20, 1997 Department of the Interior Final Administrative Proposal on the Management of Section 3406(b)(2) Water.

CVP and SWP Allocation

Reclamation operates the CVP to balance many competing objectives including water quality, fish and wildlife protection, irrigation and domestic water supply, hydroelectric power production, and flood control. In some years, the demand for water exceeds available supplies or exceeds export or conveyance capacities and Reclamation must adjust its allocation of water among the uses. Authorizing legislation, statutes, regulations, and agreements guide Reclamation's decisions in determining water allocations. In a similar manner, DWR balances the SWP's many competing objectives.

One of the critical operating decisions for the CVP and SWP is the annual water supply allocation. When specific water supply indices indicate an insufficient amount of water supply to meet all demands, allocation deficiencies are imposed depending upon the contract type. The Settlement and Exchange Contractors and the CVP wildlife refuges receive either 100 percent (normal and wet years) or 75 percent (critical years) allocation based on the Shasta Index.

The remaining and majority of CVP contracts receive allocations on a sliding scale based on a comparison of forecast demand and supply for the March through September period. As the simulation is run, CALSIM II compares water demand and available water supply for the March through September period. If the supply is greater than the demand, a full allocation is made. If the supply is less than the demand, allocations are reduced incrementally in response to the severity of the simulated shortfall. CVP M&I contracts receive allocations ranging from 50 to 100 percent. CVP agricultural contracts receive allocations ranging from 0 to 100 percent. Agricultural allocations are reduced first and reductions to the M&I allocations start after the agricultural allocations have been reduced to 75 percent of the full contract allocation. SWP allocations impose deficiencies equally to agricultural and M&I water users.

2.2.1.2 Upstream from the Delta Region - Flexible Purchase Alternative Simulation

This section describes the assumptions applied to the CALSIM II modeling and pre- and post-processing applications to simulate implementation of the EWA water purchases and fish actions proposed to occur under the Flexible Purchase Alternative.

The Flexible Purchase Alternative simulation represents the conditions that would occur with implementation of the EWA Flexible Purchase Alternative. It is assumed that the EWA Program would be implemented between 2004 and 2007. Preliminary EWA activities occurred in water years 2000, 2001 and 2002, under a series of agreements executed by the Project Agencies to provide the required water for the EWA. (See EIS/EIR Executive Summary and http://wwwoco.water.ca.gov/calfedops/2001ops.html or http://wwwoco.water.ca.gov/calfedops/2002ops.html.)

Development of the Flexible Purchase Alternative simulation utilizes the CALSIM II benchmark study used in the Baseline Condition (refer to Section 2.2.1.1). The Flexible Purchase Alternative simulation, therefore, involves the same period of record and hydrology LOD. Because the timeframe for the EWA Program is relatively short (lasting only until 2007), relative to future condition demands (represented by 2020) that are used by CALSIM II, there is little variation between 2001 demands and projected 2007 demands. As a result, the hydrology used in the CALSIM II benchmark study (LOD 2001) was determined appropriate for use in the evaluation of "future" (2007) EWA conditions.

The modeling assumptions incorporated into the CALSIM II benchmark study and utilized in further development of the Flexible Purchase Alternative results are summarized in Table 2. The sections following Table 2 provide additional detailed explanation of these parameters and assumptions.

The Flexible Purchase Alternative would allow the EWA agencies to purchase up to 600 TAF of water and would not restrict acquisition quantities upstream from the Delta or within the Export Service Area. The EWA agencies could freely combine acquisition methods, water sources, and operational flexibilities to effectively respond to annual changes in hydrology and fish behavior in the Delta.

Although the flexibility in water acquisitions incorporated into the Flexible Purchase Alternative enables and enhances the success of the program, determining the appropriate manner in which to represent the various elements of the Flexible Purchase Alternative in the modeling effort becomes complicated. Because the program is designed to be highly responsive to different conditions that may occur in any given year, there are a number of unknowns associated with its implementation.

The following sections describe the assumptions and tools used to simulate the Flexible Purchase Alternative. These methods were developed with input from and through coordination with the Project Pgencies (DWR and Reclamation) and the Management Agencies (NOAA Fisheries, USFWS, and CDFG), and were determined to be the best approach considering available information or data sets and current modeling tools and applications.

Flexible Purchase Alternative Operations

The EWA Program allows for operational changes of the CVP and SWP facilities that benefit fish. Fish actions that could be implemented to protect and enhance fish species recovery include 1) reductions in Delta export pumping at the CVP and SWP pumping plants; 2) closure of the Delta Cross Channel Gates; 3) increases in instream flow; and 4) increases in Delta outflow. Additionally, EWA assets acquired by the Project Agencies will be used to repay CVP and SWP contractors for water used for fish actions that would have otherwise been delivered to the Export Service Area.

The Project Agencies determine the quantity of water that can be made available each year to agricultural and urban contractors within the Export Service Area. The agencies then move that amount of water, either from natural flows within the Sacramento River and San Joaquin River Basins or from Project reservoirs upstream from the Delta, through the Delta using the export pumping plants.

For the purposes of modeling and associated impact assessment of the Flexible Purchase Alternative water purchases on CVP and SWP operations, instream flows, and instream water temperatures of conveying the water from the area of water purchase to the Delta assumes 1) EWA would purchase 600 TAF[1] of water from the Upstream from the Delta Region in every year, limited only by the availability of CVP and SWP export capacity to pump the purchased water; and 2) the EWA would have up to 600 TAF of water available to implement EWA fishery protection and recovery actions in the Delta. The assumed acquisitions up to 600 TAF of EWA assets would be used solely to repay the CVP and SWP for water foregone due to export pumping reductions generally implemented during the December through July period.

The effect analyses for flow-related issues for water quality, fisheries, and power resources does not depend on the location of a particular seller but on the total amount of EWA water to be transferred via a particular tributary and receiving water body. Therefore, these resources were evaluated based on the largest amount of water that EWA agencies could manage for Delta fish actions (600 TAF), from the Upstream from the Delta Region, regardless of whether the specific water sellers could be identified at this time.

Water Purchases

The Flexible Purchase Alternative covers a range of EWA water purchases extending from a minimum of 75 TAF to a maximum of 600 TAF in the Upstream from the Delta Region. The actual water purchases in any given year to support the EWA would vary based on fisheries needs, budgetary constraints and other factors. The total amount of water available for purchase by the EWA Program as assets generally would be dependent upon water year type. Assumptions (transfer allocations) specific to each river, basin or seller were developed for the long-term hydrologic record, which represents a variety of water year types. Two scenarios were developed to aid in the evaluation of the Flexible Purchase Alternative water purchase and the potential effects upon environmental resources (water quality, fisheries, and power) affected by: 1) transfer of water assets from areas within the Upstream from the Delta Region and the Export Service Area to the Delta; and 2) modifications to pumping practices at the CVP and SWP pumping plants. Constraints on the scenarios include:

- The maximum volume of water that would be obtainable from all upstream contributing sources to support a 600 TAF export at the Delta.
- The minimum water volume available from any individual upstream contributing source is zero acre-feet.

---

1 Although the Flexible Purchase Alternative calls for the purchase from the Upstream from the Delta Region of up to 600 TAF and that carriage water cost would be deducted from that quantity, for this scenario it was assumed that sufficient water would be purchased to allow the export of 600 TAF at the CVP and SWP pumping plants. See discussion of carriage water at Section 2.1.2.5. This is more water than the EWA would purchase under this alternative resulting in an impact analysis of potentially greater impacts than would occur under the Flexible Purchase Alternative. This was done so this analysis could also serve as the cumulative impact analysis. The cumulative case would be that the EWA and other water purchase programs would purchase the full 600 TAF when sufficient export capacity was available. In that case the other water purchasers would purchase sufficient water to allow the full 600 TAF to be exported at Banks and Tracy and, therefore, would purchase sufficient water to cover carriage water cost. This will require very few years during which more than the 650 TAF shown available in Table 10 will be purchased. To cover this shortage, annual crop idling was assumed to be as great as 250 TAF in both the Feather and Sacramento River regions to account for potential, presently unidentified, water purchase assets. These assumptions result in an evaluation of the worst possible case for environmental impact analysis.

The Flexible Purchase Alternative would utilize various combinations of the elements described in Chapter 2 of the EWA EIS/EIR as a means of achieving the desired water allocation. As shown in Table 10, each river system or potential selling entity may have a certain amount of water available to EWA; however, it may come from one individual source within the system or a combination of sources. As such, there could be no water available for purchase from any individual river or source for any given year. This analysis must consider the possibility of these situations because in any given year, a particular river, basin, or seller may provide no contribution to EWA. For the purpose of a comprehensive analysis, the minimum amount of purchased water that would be considered under the Flexible Purchase Alternative is zero acre-feet. However, to comply with CALFED ROD prescriptions for the minimum annual acquired surface water assets from the Upstream from the Delta Region, it is expected that a total quantity of 35 TAF will be exported, regardless of water year type. This volume of water is a relatively small amount that does not exceed the EWA's dedicated conveyance capacity in the Delta, even during wet years. The total may come from any individual river, basin, seller, or a combination of multiple sources.

Because of the uncertainty in where and what amounts water will be purchased for the EWA, it was determined that information and analyses provided in the EIS/EIR should encompass all reasonable actions. Two factors that affect the estimated EWA water purchases include 1) presently identified estimates of potential water assets (Table 10); and 2) the desire to purchase 600 TAF of water assets from the Upstream of the Delta region for the Flexible Purchase Alternative.

To compensate in part for the perpetual availability of maximum individual asset quantities, modeling performed for the Flexible Purchase Alternative, in some cases, used EWA asset quantities less than the maximum identified for a particular river, basin or seller. The result from this procedure identifies maximum EWA instream flow effects, but could misidentify maximum reservoir, landside, and economic effects. To ensure that the EWA EIS/EIR presents a thorough picture of reasonable effects in these non-instream flow areas, some analyses in the EIS/EIR take the additional step of looking at maximum utilization of identified assets. This two-level procedure guarantees that all of the effects of the EWA (instream, landside, and economic) are addressed. Identifying the location, amount, and type of potential individual water purchases in the Upstream from the Delta Region is critical to determining the instream flow, water temperature, reservoir storage change, and potential water quality effects of the EWA Program. There are numerous possible combinations of water purchases in the Upstream from the Delta Region. Multiple studies to analyze all of the combinations were not feasible because of the time and cost of such an effort. It was decided to design one set of assumptions that could be adjusted to account for all other potential water purchase combinations and allow for qualitative assessments of the potential environmental effects.

[1] Semi-Tropic WSD and Arvin-Edison WSD are within Kern County Water Agency. Their groundwater storage facilities are separate from the Agency, but they may participate in other programs that the agency helps administer, such as crop idling.

X = unknown quantity

The EWA agencies prioritized the types and amounts of water purchases in the Upstream from the Delta Region, as follows (water purchase decision priority):

- Water would be purchased first from the Upstream from the Delta Region, limited by the available SWP and CVP export capacity, and second from sellers in the Export Service Area.

- Purchases from reservoir storage would be used before any other purchase option is pursued.

- Stored groundwater purchases would be pursued as a second option after all reservoir storage purchases have been utilized.

- Groundwater substitution purchases would occur if more water were needed than can be obtained from reservoir storage and stored groundwater purchases.

- Water purchases obtained by idling rice would be pursued as a final option if more water were required to satisfy EWA requirements.

- Idling rice in the Feather River Basin would be pursued before idling rice in the Sacramento River Basin because some water from Sacramento River purchases could not be stored in Lake Shasta during April, May, and June when instream water temperature obligations require the water to be released.

These assumptions and priorities were utilized in the post-processing applications to develop model output results for the Flexible Purchase Alternative.

Fish Actions

The behavior of fish at the Delta pumps, such as the timing of their arrival (typically late winter /early spring) and the length of their stay, varies from year to year and cannot be predicted in advance. Years in which the fish arrive late and leave early may have fewer pumping reductions than other years and would have adequate assets to cover those reductions as well as providing water for upstream fish enhancements (increased instream flows).

EWA actions would be implemented primarily in the winter and spring months, which are months that the SWP and/or CVP would be required to reduce export pumping to protect and assist in restoration of listed and candidate fish species. The water supply lost due to pumping reductions during these months would be repaid in whole or in part during the summer by water acquired upstream from the Delta Region and pumped through the Delta to the downstream CVP/SWP water users. It is assumed that the water acquired reaches the Delta during July through September and is pumped at the Projects' pumping plants during that same period.

The CALSIM II benchmark study does not include the CALFED EWA actions, therefore, the post-processing tools, EWA Water Purchases.xls and EWA Routing.xls (Sections 2.1.3 and 2.1.4, respectively), were utilized to integrate the appropriate EWA actions into the modeling process to develop the Flexible Purchase Alternative simulation results used in the Upstream from the Delta Region impact analysis.

The EWA Water Purchases.xls post processing tool incorporates the assumed EWA Actions (export reductions) to simulate the CVP/SWP reservoirs changes and changes in their associated rivers in the Upstream from the Delta Region. The EWA water purchases used to represent the Flexible Purchase Alternative for this region are described in detail in Sections 2.2.1.2 and 2.2.2.2.

Delta Export Capacity

EWA asset management activities also involve use of the Delta pumps when capacity is available. Generally, drier water year types provide greater opportunities for conveyance of EWA water. In wet years, most of the Delta export conveyance is utilized by the SWP and CVP. During wet years, the Delta pumps export water at nearly 100 percent of their capacity during the summer transfer window, leaving minimal export capacity available for moving EWA assets. In drier years, the Delta export pumps are not running at capacity, leaving more capacity available to move EWA assets during the summer transfer window. During dry years, the EWA agencies would have fewer requirements to replace water lost during pumping reductions because the pumps would not have been operating at full capacity without the EWA. Therefore, the EWA project agencies may need to make fewer water acquisitions during dry years.

These EWA transfers require the utilization and implementation of various upstream combinations of groundwater substitution, stored reservoir water, and crop idling activities in order to achieve the maximum annual EWA purchase allowance (600 TAF) of effective water. Effective water is the total volume of water that is made available for export at the Delta pumping stations. To compensate for losses incurred through conveyance and the seasonality of crop idling activities, initial asset purchases may exceed 600 TAF. It is estimated that purchase losses may range between 20 to 50 percent of the initial acquisition. Table 10 considers these conditions by listing the range of the total purchases required to provide the maximum quantity (600 TAF) of water from EWA's suite of sources available for export at the Delta. In the Export Service Area, source shifting and borrowed project water also may be employed, in addition to groundwater substitution, stored reservoir water and crop idling activities.

The amount of water that would be purchased in the Upstream from the Delta Region was limited to that amount which could be exported by the SWP and CVP pumping plants after all project pumping requirements were fulfilled.

The EWA Water Purchases.xls and EWA Routing.xls post-processing tools were used to determine the amount of available Delta export capacity at the CVP and SWP pumping plants that was in excess of Project requirements and that could be used to transfer EWA assets purchased from the Upstream from the Delta Region. As discussed in Section 2.1.3.2, two limiting factors were considered in the assessment of the CALSIM II results: 1) unused export capacity (physical capacity); and 2) E/I ratio (using inflow to Delta and Delta export variables). Using pooled seasonal export capacities (July through September total), limited when necessary by the E/I ratio, from all years in the modeled period of record, the potential annual EWA export amounts ranges between 75 TAF and 600 TAF.

For modeling purposes, it was assumed that the EWA Program would have the ability to utilize the full available capacity. However, it is recognized that there are other programs with

authority to utilize Delta export capacity when it is available, and that the full amount likely would not be available to the EWA Program. Therefore, this assumption provides a conservative or worst-case representation of the impact associated with using this capacity, but the impacts would not be due solely to the EWA Program (see discussion of Cumulative Considerations below).

It is recognized that in real-time, there are a number of factors that would limit the ability of the EWA Program to utilize the full amount of export capacity including competing transfers, hydrology (including the timing of precipitation and runoff), facility outages, operational constraints, and other environmental factors and variables. Additionally, the CALFED ROD and the EWA 2003 Interim EWA Protocols establish priorities for determining and assigning the use of any excess capacity available at the CVP and SWP pumping plants. Those priorities are described below.

SWP pumping (from highest to lowest):

- First priority - SWP Pumping[2]
- Second priority - Water Transfers for SWP contractors
- Third priority - Joint Point of Diversion (JPOD) use for specific CVP Contractors (example: Cross Valley Canal)
- Fourth priority - Wheeling for CVP and EWA
- Fifth priority - Water transfers for others

CVP pumping (from highest to lowest):

- First priority - CVP Pumping[3]
- Second priority - Refuge Level IV
- Third priority - Cross Valley Canal
- Fourth priority - EWA water
- Fifth priority - Water transfers for others

Although estimates of the excess capacity that might remain for EWA purposes after other priority programs utilize what they need could be made, those estimates would not be absolutely correct in all years. If the estimates are high in any year, the potential effects of conveying EWA water from the areas where the water is purchased to, and through the Delta, could be underestimated. For this and other reasons it was assumed that all of the capacity available would be used by EWA and the resultant environmental effects analyzed for conveying the water purchased in the Upstream from the Delta Region and exporting that water. Therefore, any quantity of water purchased and utilized by the EWA and the environmental effects associated with such action would be analyzed in the EIS/EIR.

---

[2] The water that will be produced by the Sacramento Valley Water Management Agreement will be used to meet D-1641 water flow requirements, which are now being met, by the CVP and SWP. This will result in the SWP dedicating less water to meeting D-1641 flow requirement and this "saved" water would be pumped as by the SWP to SWP contractors south of the Delta. Therefore, the analysis assumes that any water produced by the Sacramento Valley Water Management Agreement for the SWP would be considered as included in SWP pumping.

[3] The Sacramento Valley Water Management Agreement affects the CVP in the same way the agreement affects the SWP as explained in footnote #2. Therefore, the analysis assumes that the water produced by the Sacramento Valley Water Management Agreement for the CVP would be considered as included in CVP pumping.

Cumulative Considerations

The Flexible Purchase Alternative, as described for modeling and impact assessment purposes, represents a cumulative condition. Although it is recognized that the EWA program may not actually purchase and transfer 600 TAF in each year of the program, there are other water acquisition and transfer programs that would purchase water and utilize excess capacity at the Delta pumping facilities. Therefore, the evaluation of purchasing and transferring 600 TAF from the Upstream from the Delta Region to the Delta and the summer exports from the Delta to the Export Service Area represents a cumulative condition in addition to a year of maximum EWA purchases from the Upstream of the Delta Region.

The other programs considered as reasonably foreseeable future actions include: implementation of the Sacramento Valley Water Settlement Agreement, other water purchases by the SWP and CVP on behalf of the Projects' water contractors, and water purchases by SWP contractors.

The Sacramento Valley Water Management Agreement ultimately will require export of up to 185 TAF in critical, dry, below normal, and in some above normal water years. However, this agreement involves staged implementation, increasing the agreed upon water exports incrementally over time, and it is anticipated that the full 185 TAF would be required sometime after 2007 (which represents the end of the EWA study period for the EWA EIS/EIR).

Because the SWP is not capable of meeting the SWP contractors' water supply requirements in many years, the contractors purchase water from areas upstream of the Delta in critically dry, dry, and some below normal water years. The CVP will utilize its share of unused SWP pumping plant export pumping capacity to export CVP stored water to CVP water contractors, the CVP's share of the Sacramento Valley Water Management Agreement water, and water purchased by CVP water contractors.

Application of Analysis

The analysis of the Flexible Purchase Alternative is based on the maximum amount of purchases (600 TAF) that might occur Upstream from the Delta on a very infrequent basis (less than 15 percent of the time). As such, this analysis depicts the maximum EWA fishery benefits achievable as well as the maximum offsetting of those benefits due to summer pumping of the EWA water. The accompanying analysis of potential environmental effects provides the EWA Project Agencies the maximum decision-making flexibility for utilizing EWA assets of any amount up to 600 TAF of water, and the maximum flexibility for pumping water purchased from the Upstream from the Delta Region to O'Neill Forebay. It also provides for flexibility in making decisions regarding EWA fish actions, not only for reducing CVP and SWP export pumping from the Delta to improve aquatic habitat, but also to perform other identified EWA fish actions such as: closing the Delta Cross-Channel gates, increasing instream flows, increasing Delta outflow, or any other aquatic habitat improvements to benefit targeted fish resources.

The analysis of the Flexible Purchase Alternative assumes all unused Delta export capacity is used by EWA. The analysis provides an evaluation of maximum impacts within the Delta because the maximum level of pumping would occur during summer months. This pumping offsets the benefits to fish achieved at other times of year due to the pumping reductions

implemented under the fish actions, thereby lowering the overall benefits to fish that would be achieved with pump reductions alone. However, not all of the unused Delta export capacity would be available to the EWA Program, so overall, the fishery benefits associated with the Flexible Purchase Alternative likely are underestimated.

By providing an assessment of regulatory compliance with the maximum water purchase amount, the agencies are afforded greater latitude in making operational decisions to implement fish actions while also keeping the Project contractors whole. The alternative also provides greater opportunities for Delta outflow benefits and for upstream flow enhancements.

The analysis represents a worst-case simulation of effects that may occur in the Upstream from the Delta Region. Therefore, purchase and transfer of less than the maximum amount generally would be expected to result in reduced environmental effects.

This analysis also may prove useful to other agencies considering water transfer programs by providing an indication of potential effects related to individual project and cumulative conditions.

Impact Assessment Comparison – Upstream from the Delta Region
The Flexible Purchase Alternative simulation was compared to the Baseline Condition simulation to identify the potential changes in the CVP/SWP hydrologic conditions (e.g., instream flow, reservoir elevations, end-of-month storage, and water temperature) that could influence water quality, fisheries, and power resources. The evaluation of environmental effects was performed by considering the modeling results from the comparison in light of the impact indicators and evaluation criteria developed for the flow-related resource areas. The impact indicators and evaluation criteria are provided in the individual resource chapters of the Draft EIS/EIR and identify the parameters evaluated, including specific locations and seasonal considerations within the area of analysis specific to the resource being evaluated.

Due to the relatively short-term nature of the EWA Program, the Flexible Purchase Alternative includes all reasonably foreseeable future projects or actions that would typically be incorporated into a cumulative condition simulation, therefore, a separate modeling simulation for the cumulative condition was not performed. As described in the EIS/EIR (Chapter 3), the modeling for a cumulative impact assessment comparison would be the same as the assessment comparing the Flexible Purchase Alternative to the Baseline Condition. Similarly, the Baseline Condition represents existing conditions as well as future No Action/No Project conditions. Therefore, a separate modeling simulation was not developed for the No Action/No Project Alternative.

2.2.2 Delta Region Analysis

Separate modeling simulations and assumptions were developed for the evaluation of flow-related resource impacts for the Delta Region analysis. The following sections describe the approach utilized to assess water quality, fisheries and power resources in the Delta.

2.2.2.1 Delta Region - Baseline Condition Simulation

The Baseline Condition for the Delta Region analysis was developed using the same modeling tools and pre- and post-processing applications as described for the Upstream from the Delta Region (Section 2.2.1), with the exception of the hydrologic period of record. The hydrologic period of record for the Delta Region analysis extends over a 15-year period, from 1979 through

1993. Although not as extensive as the 72-year period utilized for the Upstream from the Delta Region simulations, the 15-year period of record encompasses a variety of water year types and is considered representative of conditions that may occur over the EWA Program period (2004 to 2007).

The 15-year period of record for the Delta Region analyses corresponds with the data available to conduct the Delta fish salvage modeling. (Refer to Section 3.0.) It was determined appropriate that the evaluation of flow-related issues within the Delta Region analyses be consistent for all impact indicators utilized for the water quality, fisheries, and power resources.

2.2.2.2 Delta Region - Flexible Purchase Alternative Simulation

The Flexible Purchase Alternative simulation for the Delta Region analysis was developed using the same modeling tools and pre- and post-processing applications as described for the Upstream from the Delta Region with some modifications. As for the Delta Region Baseline Condition, described above, the Flexible Purchase Alternative simulation used in the Delta Region analyses is based upon a 15-year period of record.

The Flexible Purchase Alternative incorporates a high amount of flexibility into the purchases; however, exact amounts of water to be purchased every year remain unknown. To account for variability from one year to the next, the modeling effort evaluated two scenarios. The first scenario, the Maximum Water Purchase Scenario, examined a worst case for environmental effects and a best case for fish benefits: the EWA project agencies purchased the maximum amount possible from the Upstream from the Delta Region. The second scenario, the Typical Water Purchase Scenario, examined a more typical year of operations to quantify adverse and beneficial effects. This scenario, however, like the Maximum Water Purchase Scenario, assumes that all unused Delta export pumping capacity for the summer months (July through September) would be available to the EWA Program. While this assumption permits evaluation of the potential worst-case for EWA export pumping, there are other water acquisition and transfer programs and SWP/CVP programs that have priority access to use this available pumping capacity. Therefore, this scenario does not necessarily represent the conditions that would be expected to occur for any given year of the program.

In effect, these two scenarios "bracket" the evaluation of water quality, fisheries, and power resources impacts related to changes in Delta pumping associated with implementation of the EWA Program. Assumptions specific to each scenario are described in the following sections.

<u>Maximum Water Purchase Scenario</u>

Operation of the Flexible Purchase Alternative under this scenario assumes 1) EWA would purchase 600 TAF of water from the Upstream from the Delta Region in every year, limited only by the availability of CVP and SWP export capacity to pump the purchased water; and 2) the EWA would have up to 600 TAF of water available to implement EWA fishery protection and recovery actions in the Delta. The assumed acquisitions of up to 600 TAF of EWA assets are used solely to repay the CVP and SWP for water not pumped during export pumping reductions (associated with EWA fish actions generally implemented during the December through July period).

Based on these assumptions, the results of this analysis describe the maximum adverse environmental effects within water bodies (reservoirs and river systems) in the Upstream from

the Delta Region because it assumes purchases from this region are based upon the maximum amount of water that that can be pumped from the Delta. This analysis also provides an analysis of the maximum potential fishery benefits that could be provided by the EWA Program under the Flexible Purchase Alternative because the maximum amount of water that could be transferred to the Delta would be purchased each year.

The modeling results for the Flexible Purchase Alternative assumes all unused Delta export capacity is used by EWA. The analysis provides an evaluation of maximum impacts within the Delta because the maximum level of pumping would occur during summer months. This pumping offsets the fishery benefits achieved at other times of year due to the pumping reductions implemented under the fish actions, thereby lowering the overall fishery benefit that would be achieved with pump reductions alone. However, not all of the unused Delta export capacity would be available to the EWA Program, so overall, the fishery benefits associated with the Flexible Purchase Alternative likely are underestimated.

The purchase of EWA assets is modeled assuming that the program would first obtain EWA variable assets such as relaxation of the allowable E/I ratio in the D-1641 water rights decision as allowed by that decision for fishery aquatic habitat improvement, then, additional purchases would be made from the Upstream from the Delta Region (to the extent that Delta export capacity is available).

Maximum Purchase Scenario - Specific EWA Fish Actions

The development of modeling assumptions for this scenario included the identification of potential specific EWA actions that would likely be imposed for the conditions represented by the historical hydrologic period of record, assuming current level of demand and regulatory conditions.

Because of the complexities inherent in developing a specific list of actions applied to historical conditions, it is possible that the EWA actions selected and used in the modeling of this scenario do not exactly reflect what the management and project agencies may decide each year. Still, the advantages of providing a quantitative evaluation of potential conditions outweighs the uncertainties associated with this method. A substantial amount of information and data are available and were utilized in the determination and assignment of specific actions for each of the study years (1979 to 1993). These sources include:

- CALFED agencies' staff and stakeholder representatives studied how the CVP and SWP would be operated to determine how EWA would have been implemented for the period 1981 to 1994. They used operations model output, fish salvage data, water temperature and turbidity data. This work was relied on heavily for the EWA EIS/EIR Delta Region analysis; in particular, to estimate the EWA asset requirements to allow the EWA management agencies to ensure provision of ESA commitments of the CVP and SWP. Additionally, review of these studies provides insight into the decision-making strategies developed by the agencies to determine the likely EWA actions that would occur and the priorities used by the management and project agencies to determine EWA assets when the total amount is insufficient to implement all EWA actions the if unlimited assets were available.

- The EWA management agencies implemented EWA actions over the past three years. (2001 through 2003), Actions were generally one-year water transfers with willing sellers approved under CEQA initial studies/negative declarations and NEPA environmental assessments/findings of no significant impact. Experience gained in making these purchase, water transfers and in implementing EWA fish actions provides valuable real-time information regarding the types of actions the agencies select with limited data during the year as well as some indication of how the fish may behave under various hydrologic and operational conditions.

- The historical fish salvage at the Tracy Pumping Plant and Banks Pumping Plant.

- Delta flow conditions available from CALSIM II.

- Delta water quality conditions available from DSM2 (using input data from the CALSIM II model).

The EWA actions and the purpose for selecting each action assumed in the Maximum Water Purchase Scenario are shown in Table 11. Export pumping of purchased water begins on July 1 unless an EWA action occurs in July or it is otherwise delayed if fish species of concern are observed in the Delta. Under such conditions, export pumping of purchased water would not start until the EWA action is completed.

Table 11
EWA Actions Simulated for the Maximum Water Purchase Scenario

Water Year	*Year Type*	*EWA Actions*	*Reason for Action*
1979	Below Normal	Dec – Reduce export pumping by 30 TAF	Export reductions required to meet Delta water quality standards when the Delta Cross Channel gates are closed for more than 45 days and for reduction of spring-run Chinook salmon salvage
		Jan - Reduce export pumping by 30 TAF	Same as above
		Feb - Reduce export pumping by 30 TAF	Reduce spring and possibly winter-run Chinook salmon salvage. Also reduces adult delta smelt salvage.
		Mar -Reduce export pumping by 60 TAF	Reduce winter-run Chinook salmon salvage.
		Apr. 1st – Apr. 14th –Reduce export pumping to 4,000 cfs.	Reduce delta smelt salvage going into VAMP. Also reduces steelhead, splittail, and salmon salvage.
		April 15th – May 15th – VAMP @ 1,500 cfs export.	Implement VAMP study.
		May 16th – May 31st - Reduce export pumping to 5,000 cfs.	Reduce delta smelt, steelhead, splittail, and salmon salvage.
		Jun - Reduce exports by 60 TAF	Reduce delta smelt and heavy splittail salvage.
1980	Above Normal	Dec – Reduce export pumping by 60 TAF	Export reductions required to meet Delta water quality standards when the Delta Cross Channel gates are closed for more than 45 days and for reduction of spring-run Chinook salmon salvage.
		Jan - Reduce export pumping by 30 TAF	Reduce spring-run Chinook salmon and splittail salvage.
		Feb - Reduce export pumping by 30 TAF	Reduce winter-run Chinook salmon, and adult delta smelt salvage.
		Mar -Reduce export pumping by 20 TAF	Reduce winter-run Chinook salmon salvage.

Table 11 *EWA Actions Simulated for the Maximum Water Purchase Scenario*			
Water Year	***Year Type***	***EWA Actions***	***Reason for Action***
		Apr. 1st – Apr. 14th –Reduce export pumping to 3,000 cfs.	Reduce delta smelt salvage going into VAMP. Also reduces splittail, and salmon salvage.
		April 15th – May 15th – VAMP @ 1,500 cfs total pumping.	Implement VAMP study.
		Jun - Reduce Banks P.P. export pumping to 2,000 cfs.	Reduce delta smelt and heavy splittail salvage.
		Jul 1st – Jul 15th - Reduce export pumping by 1,500 cfs	Reduce salvage of delta smelt
1981	Dry	Dec – Reduce export pumping by 20 TAF	Export reductions may be required to meet Delta water quality standards when the Delta Cross Channel gates are closed for more than 45 days and for reduction of spring-run Chinook salmon salvage
		Feb - Reduce export pumping by 20 TAF	Reduce winter/spring-run Chinook salmon, splittail, steelhead, and adult delta smelt salvage.
		Mar -Reduce export pumping by 200 TAF	Reduce winter-run Chinook salmon, steelhead, and adult delta smelt salvage.
		Apr. 1st – Apr. 14th –Reduce export pumping to 4,000 cfs	Reduce delta smelt, steelhead, splittail, and salmon salvage.
		April 15th – May 15th – VAMP @ 1,500 cfs export.	Implement VAMP study.
		May 16th – 31st – Reduce export pumping to 2,500 cfs	Reduce delta smelt and heavy splittail salvage.
		Jun - Reduce export pumping by 30 TAF,	Reduce delta smelt and heavy splittail salvage
		Jul - Reduce export pumping by 90 TAF	Reduce delta smelt salvage
1982	Wet	Dec – Reduce export pumping by 40 TAF	Export reductions may be required in Dec to meet Delta water quality standards when the Delta Cross Channel gates are closed for more than 45 days and for reduction of spring-run Chinook salmon salvage
		Jan – Reduce export pumping by 40 TAF	Reduce spring-run salmon salvage
		Feb - Reduce export pumping by 60 TAF	Reduce winter-run salmon, splittail, steelhead, and adult delta smelt.
		Mar -Reduce export pumping by 60 TAF	Reduce salvage of winter/spring-run salmon, steelhead and adult delta smelt salvage.
		Apr –Reduce export pumping by 120 TAF	Reduce heavy salvage of steelhead and salmon salvage.
		May - Reduce export pumping by 120 TAF.	Reduce splittail, steelhead and salmon salvage.
		Jun - Reduce export pumping by 90 TAF,	Reduce delta smelt and splittail salvage
1983	Wet	Dec – Reduce export pumping by 150 TAF	Reduce heavy spring-run Chinook salmon salvage
		Jan – Reduce export pumping by 120 TAF	Reduce spring-run salmon and adult delta smelt salvage
		Feb - Reduce export pumping by 120 TAF	Reduce spring/winter-run salmon and adult delta smelt salvage.
		Mar -Reduce export pumping by 60 TAF	Reduce winter/spring-run salmon, steelhead, and adult delta smelt salvage.
		Apr –Reduce export pumping by 60 TAF.	Reduce salmon salvage and heavy splittail salvage.
		May - Reduce export pumping by 60 TAF.	Reduce heavy splittail and salvage of steelhead salvage.
		Jun - Reduce export pumping by 120 TAF,	Reduce delta smelt and splittail salvage.

Table 11
EWA Actions Simulated for the Maximum Water Purchase Scenario

Water Year	*Year Type*	*EWA Actions*	*Reason for Action*
1984	Wet	Feb - Reduce export pumping by 20 TAF	Reduce winter/spring-run Chinook salmon and splittail salvage.
		Mar -Reduce export pumping by 60 TAF	Reduce winter-run Chinook salmon salvage.
		Apr. 1st – Apr. 14th –Reduce export pumping to 5,000 cfs.	Reduce splittail, and salmon salvage
		April 15th – May 15th – VAMP @ 1,500 cfs export.	Implement VAMP study.
		May 16th – May 31st - Reduce export pumping to 4,000 cfs.	Reduce delta smelt and splittail salvage.
		Jun 1st – Jun 15th - Reduce export pumping by 60 TAF.	Reduce delta smelt and splittail salvage.
1985	Dry	Dec – Reduce export pumping by 60 TAF.	Reduce spring run Chinook salmon salvage.
		Feb - Reduce export pumping by 20 TAF	Reduce winter/spring-run Chinook salmon and splittail salvage.
		Mar -Reduce export pumping by 60 TAF	Reduce winter-run Chinook salmon, steelhead and splittail salvage
		Apr. 1st – Apr. 14th –Reduce export pumping to 4,000 cfs	Reduce splittail and salmon salvage.
		April 15th – May 15th – VAMP @ 1,500 cfs export.	Implement VAMP study
		Jun 1st – Jun 20th - Reduce export pumping by 150 TAF.	Reduce heavy delta smelt and splittail salvage.
1986	Wet	Dec – Reduce export pumping by 30 TAF.	Export reductions may be required to meet Delta water quality standards when the Delta Cross Channel gates are closed for more than 45 days and for reduction of spring-run Chinook salmon salvage.
		Jan - Reduce export pumping by 30 TAF.	Reduce spring-run Chinook salmon salvage.
		Feb - Reduce export pumping by 90 TAF	Reduce spring-run salmon and adult delta smelt salvage.
		Mar -Reduce export pumping by 150 TAF	Reduce splittail, steelhead, and winter-run salmon salvage.
		Apr - Reduce export pumping by 90 TAF.	Reduce salmon, delta smelt and splittail salvage.
		May - Reduce export pumping by 90 TAF.	Reduce delta smelt salvage and the heavy salvage of splittail.
		Jun - Reduce export pumping by 120 TAF.	Reduce delta smelt salvage and the heavy salvage of splittail.
1987	Dry	Dec – Reduce export pumping by 30 TAF.	Export reductions may be required to meet Delta water quality standards when the Delta Cross Channel gates are closed for more than 45 days and for reduction of spring-run Chinook salmon salvage
		Jan - Reduce export pumping by 30 TAF.	Same as above
		Feb - Reduce export pumping by 30 TAF	Reduce winter/spring-run Chinook salmon salvage
		Mar -Reduce export pumping by 200 TAF	Reduce salvage of winter-run Chinook salmon salvage.
		Apr. 1st – Apr. 14th –Reduce export pumping to 3,000 cfs	Reduce steelhead, and salmon salvage.
		April 15th – May 15th – VAMP @ 1,500 cfs export.	Implement VAMP study.
		Jun 1st – Jun 20th - Reduce export pumping by 70 TAF.	Reduce delta smelt and splittail salvage.

Table 11 *EWA Actions Simulated for the Maximum Water Purchase Scenario*			
Water Year	***Year Type***	***EWA Actions***	***Reason for Action***
		Jul – Reduce export pumping by 30 TAF the first week of July.	Reduce delta smelt salvage
1988	Critical	Dec – Reduce export pumping by 120 TAF.	Export reductions may be required to meet Delta water quality standards when the Delta Cross Channel gates are closed for more than 45 days and for reduction of spring-run Chinook salmon salvage
		Jan - Reduce export pumping by 90 TAF.	Reduce spring-run Chinook salmon salvage.
		Feb - Reduce export pumping by 90 TAF	Reduce winter/spring-run Chinook salmon salvage.
		Apr 1st –Apr 14th – reduce export pumping to 3,500 cfs.	Reduce salmon, delta smelt, and splittail salvage.
		April 15th – May 15th – VAMP @ 1,500 cfs export	Implement VAMP study
		May 16th – May 31st - Reduce export pumping to 1,500 cfs.	Reduce delta smelt and splittail salvage
1989	Dry	Jan - Reduce export pumping by 30 TAF.	Export reductions may be required to meet Delta water quality standards when the Delta Cross Channel gates are closed for more than 45 days and for reduction of spring-run Chinook salmon salvage
		Feb - Reduce export pumping by 30 TAF	Reduce spring-run Chinook salmon and adult delta smelt salvage.
		Mar -Reduce export pumping by 90 TAF	Reduce winter/spring-run Chinook salmon and splittail salvage.
		April 15th – May 15th – VAMP @ 1,500 cfs export pumping.	Implement VAMP study.
		May 16th – May 31st - Reduce export pumping to 4,500 cfs.	Reduce delta smelt and splittail salvage
		Jun – Reduce export pumping by 30 TAF.	Reduce delta smelt and splittail salvage
		Jul - Reduce export pumping by 90 TAF	Reduce delta smelt and splittail salvage
1990	Critical	Dec – Reduce export pumping by 30 TAF.	Export reductions may be required to meet Delta water quality standards when the Delta Cross Channel gates are closed for more than 45 days and for reduction of spring-run Chinook salmon salvage
		Jan - Reduce export pumping by 90 TAF.	Same as above.
		Feb - Reduce export pumping by 90 TAF	Reduce winter/spring-run Chinook salmon salvage
		Mar -Reduce export pumping by 120 TAF	Reduce winter-run Chinook salmon, split, and adult delta smelt salvage
		Jun – Reduce export pumping to 1,500 cfs	Reduce delta smelt salvage.
1991	Critical	Mar -Reduce export pumping by 120 TAF	Reduce winter-run Chinook salmon, steelhead, adult delta smelt, and splittail salvage.
		Apr 1st –Apr 14th – reduce export pumping to 1,500 cfs.	Reduce salmon, adult delta smelt, and splittail salvage.
		April 15th – May 15th – VAMP @ 1,500 cfs export	Implement VAMP study
		May 16th – May 31st - Reduce export pumping to 1,500 cfs.	Reduce delta smelt and splittail salvage

Table 11
EWA Actions Simulated for the Maximum Water Purchase Scenario

Water Year	*Year Type*	*EWA Actions*	*Reason for Action*
1992	Critical	Jan - Reduce export pumping by 30 TAF	Export reductions may be required to meet Delta water quality standards when the Delta Cross Channel gates are closed for more than 45 days and for reduction of spring-run Chinook salmon salvage
		Feb - Reduce export pumping by 90 TAF	Reduce winter/spring-run Chinook salmon, steelhead, adult delta smelt, and splittail salvage.
		Mar -Reduce export pumping by 120 TAF	Reduce winter-run Chinook salmon, steelhead, adult delta smelt, and splittail salvage.
		Apr 1st –Apr 14th – reduce export pumping to 2,500 cfs.	Reduce salmon salvage
		Apr 15th – 30th – reduce export pumping to 1,500 cfs	Reduce salmon salvage
1993	Above Normal	Jan - Reduce export pumping by 30 TAF	Export reductions may be required to meet Delta water quality standards when the Delta Cross Channel gates are closed for more than 45 days and for reduction of spring-run Chinook salmon, splittail, and steelhead salvage
		Feb - Reduce export pumping by 30 TAF	Reduce winter/spring-run Chinook salmon, steelhead, adult delta smelt, and splittail salvage.
		Mar -Reduce export pumping by 90 TAF	Reduce winter-run Chinook salmon, steelhead, adult delta smelt, and splittail salvage.
		Apr 1st –Apr 14th – reduce export pumping to 10,000 cfs.	Reduce salmon and steelhead salvage.
		Apr 15th – May15th - VAMP @ 1,500 cfs export.	Implement VAMP
		Jun 1st – 15th - Reduce export pumping to 6,000 cfs	Reduce delta smelt and splittail salvage

The Maximum Water Purchase Scenario assumes that up to 600 TAF of EWA assets are available each year and that those 600 TAF would be purchased from the Upstream from the Delta Region limited only by available Delta export pumping capacity at the CVP and SWP pumping plants. The EWA actions assumed to occur under the Maximum Water Purchase Scenario (Table 11) do not require 600 TAF of EWA assets in every year. In those years, the modeling assumes that only the amount of EWA assets required are purchased from the Upstream from the Delta Region or the amount of available export pumping capacity at the CVP and SWP pumping plants, whichever is less.

Calculations were performed to determine the amount of export reductions associated with the EWA actions assumed under the Maximum Water Purchase Scenario (Table 12), the EWA assets required to implement the EWA actions, and the amount of purchased water pumped at the Banks and Tracy pumping plants to CVP and SWP contractors during the July through September period for each of the 15 years studied in this analysis.

Table 12 Maximum Water Purchase Scenario - EWA Export Reductions, EWA Assets Required, and Water Purchase Pumping (TAF)			
Analysis Year	**EWA Export Reductions**	**EWA Assets Required**	**Pumping of EWA Water at Banks and/or Tracy Pumping Plants**
1979	604	484[a]	213
1980	674	534[a]	320
1981	623	623[b]	116
1982	530	0[c]	530[d]
1983	690	0	690[b]
1984	472	392[a]	234
1985	443	443	75
1986	600	600	455
1987	525	525	328
1988	406	406	444
1989	326	326	80
1990	376	376	360
1991	241	241	241
1992	258	258	258
1993	380	380	287

a San Luis Reservoir reaches full storage even with the EWA export reductions and with SWP Article 21 water deliveries.

b The amount of EWA cost over 600,000 acre-feet would be covered by available CVPIA (b)(2) water and/or Variable EWA assets.

c 1982 & 1983 were very wet years. The water loss due to EWA required export pumping curtailments can be recovered by export pumping of Delta surplus flows during the summer months. The loss of unused CVP and SWP export pumping during the summer months would not affect any other water user or the CVP because no water purchases of water from the Upstream from the Delta Region by SWP contractors, the CVP on behalf of the Project's contractors, or transfer of upstream CVP stored water would be done in these very wet water years.

d This is pumping of Delta surplus water and not purchased water.

As discussed in Section 1.1, EWA assets are made up of variable operational assets, water purchased from the Upstream from the Delta Region, and water purchased from the Export Service Area. The amount of variable operational assets available is not known, although some amount of variable operational assets will be available in almost every year. The problem of not knowing the quantity of variable operational assets available is handled in the Flexible Water Purchase Alterative analyses (Maximum Water Purchase Scenario and Typical Water Purchase Scenario) by assuming that all assets will be developed through water purchases. This means that the environmental effects of more water purchases than will actually occur are analyzed because the amount of water available from variable operational asset would reduce the assumed water purchases. For, example, Table 12 shows that in three years (1988, 1991, and 1992) all of the required EWA assets for those years are produced from purchases from the Upstream from the Delta Region. In real-time operation, the amount of water required to be purchased from the Upstream from the Delta Region would be reduced by the amount of water available from those years' variable operational assets.

Another use of the variable operational assets is shown in 1981. In that year more than the assumed 600 TAF of assets would be required to implement the EWA actions. The additional assets would come from that year's variable operational assets.

Typical Water Purchase Scenario

The Typical Water Purchase Scenario is intended to characterize more typical EWA purchases in contrast to the Maximum Water Purchase Scenario. However, this scenario, like the Maximum Water Purchase Scenario, assumes that all unused Delta export pumping capacity for

the summer months (July through September) would be available to the EWA Program. While this assumption permits evaluation of the potential worst-case for EWA export pumping, there are other water acquisition and transfer programs and SWP/CVP programs that have priority access to use this available pumping capacity. Therefore, this scenario does not necessarily represent the conditions that would be expected to occur for any given year of the program. The assumptions used in the Typical Water Purchase Scenario are as follows:

- It is anticipated that the EWA Program would only infrequently require 600 TAF of water to achieve fish protection objectives in the Delta.

- The EWA project agencies may not have the funding required in all years to develop 600 TAF of EWA assets.

- The actual purchases from the Upstream from the Delta Region are limited by available CVP and SWP unused export pumping capacity. The studies using the CALSIM II current demand benchmark studies (see Figure 1) show that the Projects have sufficient excess export capacity to pump 600 TAF only 15 percent of the time (based on an assessment of pooled seasonal export capacities for July through September for the years included in the study) during the 1922-1993 period of analysis, and that those occasions all occur in critically dry years. Studies also have shown that the EWA's greatest need for assets (from 400 TAF to 600 TAF) occurs during above normal and wet years and that during very dry years the EWA requires the least amount of water (200 TAF to 250 TAF) to achieve the fish protection objectives in the Delta. Therefore, it is more likely that the EWA need for as much as 600 TAF would occur when capability to export that water from the Delta is limited. Further, when the export capacity is available, the EWA would require a much smaller amount of water to achieve the EWA fish protection objectives in the Delta.

- Additionally, it is unlikely that all of the available unused CVP and SWP export pumping capacity would be available to the EWA Program as other projects and programs have priority access/use of the export capacity.

Assumptions for the Typical Water Purchase Scenario reflect EWA operations that are likely closer to how the EWA actually would be operated in the next few years. The water purchase assumptions for the Typical Water Purchase Scenario incorporate consideration of water year types, as listed shown below.

- In wet and above normal years, EWA assets would total 400 TAF. The amount of water purchased from the Upstream from the Delta Region and pumped at the CVP and SWP pumping plants would be either 400 TAF, or the total unused CVP and SWP export pumping capacity available in a specific water year, whichever is less.

- In below normal and dry years, except during the second dry year in a multi–year drought period, EWA assets would total 300 TAF. The amount of water purchased from the Upstream from the Delta Region and pumped at the CVP and SWP pumping plants would be either 300 TAF, or the total unused CVP and SWP export pumping capacity available in a specific water year, whichever is less.

- In the second dry year of a multi-year drought period and the first critical year to occur during a drought period, EWA assets would total 250 TAF. The amount of water purchased from the Upstream from the Delta Region and pumped at the CVP and SWP pumping plants would be either 250 TAF, or the total unused CVP and SWP export pumping capacity available in a specific water year, whichever is less.

- In critical water years that occur during drought periods other than the first critical year to occur in the drought, EWA assets would total 200 TAF. The amount of water purchased from the Upstream from the Delta Region and pumped at the CVP and SWP pumping plants would be either 200 TAF, or the total unused CVP and SWP export pumping capacity available in a specific water year, whichever is less.

The assumptions identified above will provide an estimate of the most likely fishery benefits that would be provided by the EWA Program considering implementation of EWA fish actions (generally between December and July) and summer pumping (July or August through September) of EWA water purchased from the Upstream from the Delta Region at the CVP and SWP pumping plants. The determination of net benefits considers the potential adverse effects of EWA exports during the summer that are then offset by the EWA fishery benefits achieved by pumping reductions during other times of the year.

Typical Water Purchase Scenario - Specific EWA Fish Actions

Table 13 shows the EWA actions and the reason for selecting each action assumed for the Typical Water Purchase Scenario.

Table 13
EWA Actions Simulated for the Typical Water Purchase Scenario

Water Year	***Year Type***	***EWA Actions***	***Reason for Action***
1979	Below Normal	Dec – Reduce export pumping by 10 TAF	Export reductions required to meet Delta water quality standards when the Delta Cross Channel gates are closed for more than 45 days and for reduction of spring-run Chinook salmon salvage
		Jan - Reduce export pumping by 10 TAF	Same as above
		Feb - Reduce export pumping by 20 TAF	Reduce spring and possibly winter-run Chinook salmon salvage. Also reduces adult delta smelt salvage.
		Mar -Reduce export pumping by 40 TAF	Reduce salvage of winter-run Chinook salmon salvage.
		Apr. 1st – Apr. 14th –Reduce export pumping by 30 TAF.	Reduce delta smelt salvage going into VAMP. Also reduces steelhead, splittail, and salmon salvage
		April 15th – May 15th – VAMP @ 3,200 cfs export.	Implement VAMP study.
		May 16th – May 31st – Reduce export pumping to 5,500 cfs	Reduce delta smelt and splittail salvage.
		Jun - Reduce exports by 60 TAF	Reduce delta smelt and heavy splittail salvage.
1980	Above Normal	Dec – Reduce export pumping by 60 TAF	Export reductions required to meet Delta water quality standards when the Delta Cross Channel gates are closed for more than 45 days and for reduction of spring-run Chinook salmon salvage. Same as above plus reduce adult delta smelt salvage
		Jan - Reduce export pumping by 30 TAF	Reduce winter/spring-run Chinook and splittail salvage
		Feb - Reduce export pumping by 30 TAF	Reduce winter-run Chinook salmon, and adult delta smelt salvage.

Table 13 ***EWA Actions Simulated for the Typical Water Purchase Scenario***			
Water Year	***Year Type***	***EWA Actions***	***Reason for Action***
		Mar -Reduce export pumping by 20 TAF	Reduce winter-run Chinook salmon salvage
		Apr. 1st – Apr. 14th –Reduce export pumping to 4,000 cfs.	Reduce delta smelt salvage going into VAMP. Also reduces splittail, and salmon salvage
		April 15th – May 15th – VAMP @ 3,200 cfs total pumping.	Implement VAMP study
		Jun - Reduce Banks P.P. export pumping to 1,500 cfs.	Reduce delta smelt and heavy splittail salvage
		Jul - Reduce export pumping by 1,500 cfs	Reduce delta smelt salvage
1981	Dry	Dec – Reduce export pumping by 20 TAF	Export reductions may be required to meet Delta water quality standards when the Delta Cross Channel gates are closed for more than 45 days and for reduction of spring-run Chinook salmon salvage.
		Feb - Reduce export pumping by 20 TAF	Reduce salvage of winter-run Chinook salmon, steelhead, and adult delta smelt salvage
		Mar -Reduce export pumping by 60 TAF	Reduce delta smelt, steelhead, splittail, and salmon salvage.
		Apr. 1st – Apr. 14th –Reduce export pumping to 5,000 cfs.	Implement VAMP study
		April 15th – May 15th – VAMP @ 1,500 cfs export	Reduce delta smelt and heavy splittail salvage
		May 16th – 31st – Reduce export pumping to 4,000 cfs	Reduce delta smelt salvage
		Jun - Reduce export pumping by 30 TAF	Reduce delta smelt salvage
		Jul - Reduce export pumping by 30 TAF.	Reduce delta smelt salvage.
1982	Wet	Dec – Reduce export pumping by 40 TAF	Export reductions may be required in Dec to meet Delta water quality standards when the Delta Cross Channel gates are closed for more than 45 days and for reduction of spring-run Chinook salmon salvage
		Jan – Reduce export pumping by 40 TAF	Reduce spring-run salmon salvage.
		Feb - Reduce export pumping by 60 TAF	Reduce winter-run salmon, splittail, steelhead, and adult delta smelt salvage
		Mar -Reduce export pumping by 60 TAF	Reduce winter/spring-run salmon, steelhead and adult delta smelt salvage.
		Apr –Reduce export pumping by 120 TAF	Reduce heavy steelhead and salmon salvage
		May - Reduce export pumping by 120 TAF.	Reduce splittail, steelhead and salmon salvage
		Jun - Reduce export pumping by 90 TAF	Reduce delta smelt and splittail salvage
1983	Wet	Dec – Reduce export pumping by 150 TAF	Reduce heavy spring-run Chinook salmon salvage.
		Jan – Reduce export pumping by 120 TAF	Reduce spring-run salmon and adult delta smelt salvage
		Feb - Reduce export pumping by 120 TAF	Reduce run/winter-run salmon and adult delta smelt salvage
		Mar -Reduce export pumping by 60 TAF	Reduce winter/spring-run salmon, steelhead, and adult delta smelt salvage.
		Apr –Reduce export pumping by 60 TAF.	Reduce salmon salvage and heavy splittail salvage.
		May - Reduce export pumping by 60 TAF.	Reduce heavy splittail salvage and steelhead salvage.
		Jun - Reduce export pumping by 90 TAF	Reduce delta smelt and splittail salvage

Table 13 *EWA Actions Simulated for the Typical Water Purchase Scenario*			
Water Year	***Year Type***	***EWA Actions***	***Reason for Action***
1984	Wet	Feb - Reduce export pumping by 20 TAF	Reduce winter/spring-run Chinook salmon and splittail salvage

		April 15th – May 15th – VAMP @ 1,500 cfs export.	Implement VAMP study
		May 16th – May 31st - Reduce export pumping to 1,500 cfs.	Reduce delta smelt and splittail salvage.
		Jun 1st – Jun 20th – Reduce export pumping by 30 TAF	Reduce delta smelt and splittail salvage.
1989	Dry	Dec – Reduce export pumping by 20 TAF.	Export reductions may be required to meet Delta water quality standards when the Delta Cross Channel gates are closed for more than 45 days and for reduction of spring-run Chinook salmon salvage
		Jan - Reduce export pumping by 30 TAF.	Same as above.
		Feb - Reduce export pumping by 30 TAF	Reduce spring-run Chinook salmon and adult delta smelt salvage.
		Mar -Reduce export pumping by 90 TAF	Reduce winter/spring-run Chinook salmon and splittail salvage.
		April 15th – May 15th – VAMP @ 1,500 cfs export pumping	Implement VAMP study
		May 16th – May 31st - Reduce export pumping to 4,500 cfs	Reduce delta smelt and splittail salvage
		Jun – Reduce export pumping by 30 TAF	Reduce delta smelt and splittail salvage
1990	Critical	Dec – Reduce export pumping by 30 TAF.	Export reductions may be required to meet Delta water quality standards when the Delta Cross Channel gates are closed for more than 45 days and for reduction of spring-run Chinook salmon salvage
		Jan - Reduce export pumping by 30 TAF	Same as above
		Feb - Reduce export pumping by 30 TAF	Reduce winter/spring-run Chinook salmon salvage.
		Mar -Reduce export pumping by 60 TAF	Reduce winter-run Chinook salmon, splittail, and adult delta smelt salvage
		Jun – Reduce export pumping to 1,500 cfs	Reduce delta smelt salvage
		Jul 1st – 15th – Reduce export pumping to 1,500 cfs	Reduce delta smelt salvage
1991	Critical	Mar -Reduce export pumping by 60 TAF	Reduce winter-run Chinook salmon, steelhead, adult delta smelt, and splittail salvage
		Apr 1st –Apr 14th – reduce export pumping to 1,500 cfs.	Reduce salmon, adult delta smelt, and splittail salvage.
		April 15th – May 15th – VAMP @ 1,500 cfs export.	Implement VAMP study
		May 16th – May 31st - Reduce export pumping to 2,500 cfs.	Reduce delta smelt and splittail salvage
		Jun – Reduce export pumping by 60 TAF	Reduce delta smelt and splittail salvage
1992	Critical	Jan - Reduce export pumping by	Export reductions may be required to meet Delta

Table 13 EWA Actions Simulated for the Typical Water Purchase Scenario			
Water Year	**Year Type**	**EWA Actions**	**Reason for Action**
		30 TAF	water quality standards when the Delta Cross Channel gates are closed for more than 45 days and for reduction of spring-run Chinook salmon salvage
		Feb - Reduce export pumping by 90 TAF	Reduce winter/spring-run Chinook salmon, steelhead, adult delta smelt, and splittail salvage
		Mar -Reduce export pumping by 120 TAF	Reduce winter-run Chinook salmon, steelhead, adult delta smelt, and splittail salvage.
		Apr 1st –Apr 14th – reduce export pumping to 2,500 cfs	Reduce salmon salvage
		Apr 15th – Apr 30th – reduce export pumping to 1,500 cfs	Reduce salmon salvage
1993	Above Normal	Jan - Reduce export pumping by 20 TAF	Export reductions may be required to meet Delta water quality standards when the Delta Cross Channel gates are closed for more than 45 days and for reduction of spring-run Chinook salmon, splittail, and steelhead salvage
		Feb - Reduce export pumping by 30 TAF	Reduce winter/spring-run Chinook salmon, steelhead, adult delta smelt, and splittail salvage
		Mar -Reduce export pumping by 60 TAF	Reduce winter-run Chinook salmon, steelhead, adult delta smelt, and splittail salvage
		Apr 15th – May15th - VAMP @ 3,200 cfs export	Implement VAMP
		Jun 1st – 10th - Reduce export pumping to 6,000 cfs	Reduce delta smelt and splittail salvage

The Typical Water Purchase Scenario assumes that the EWA asset purchases would vary according to water year type and that those assets would be provided by water purchased from the Upstream from the Delta Region, limited only by available export pumping capacity at the CVP and SWP pumping plants. The export pumping of this purchased water starts on July 1st unless an EWA action occurs in July, or if it is determined that fish species of concern are observed within the Delta. In that case, export pumping of the purchased water does not start until the EWA action is completed. Table 14 displays the amount of export reductions due to the EWA actions shown in Table 13, the EWA cost due to the EWA actions, and the amount of purchased water pumped during the July through September period for each of the study year.

2.2.2.3 Delta Region - Fixed Purchase Alternative Simulation

EWA assets are made up of variable operational assets, water purchased from the Upstream from the Delta Region, and water purchased from the Export Service Area. The amount of variable operational assets available is not known although some amount of variable operational assets will be available in almost every year. Not knowing the quantity of variable operational assets available annually is not a problem in the Flexible Water Purchase Alterative analyses (Maximum Water Purchase Scenario and Typical Water Purchase Scenario) because the alternative assumes that all assets will be acquired through water purchases. The result is the amount of water purchases that are analyzed to determine environmental effects is greater than the amount of water that will actually have to be purchased because that amount will be reduced by the amount of variable operational assets available each year.

Table 14
Typical Water Purchase Scenario EWA Export Reductions, EWA Assets Required, and Water Purchase Pumping (TAF)

Analysis Year	Export Reductions	EWA Assets Required	Pumping of EWA Water at Banks and/or Tracy Pumping Plants
1979	341	271[a]	213
1980	560	430[a]	254
1981	348	348	116
1982	530	330[a]	282
1983	690	0[b]	690[c]
1984	370	290[4]	234
1985	326	326	75
1986	450	450	380
1987	290	290	290
1988	242	242	242
1989	256	256	120
1990	202	202	202
1991	210	210	210
1992	258	258	258
1993	242	242	242

a San Luis Reservoir reaches full storage even with the EWA export reductions and with SWP Article 21 water deliveries.
b 1982 & 1983 were very wet years. The water loss due to EWA required export pumping curtailments can be recovered by export pumping of Delta surplus flows during the summer months. The loss of unused CVP and SWP export pumping during the summer months would not affect any other water user or the CVP because no water purchases of water from the Upstream from the Delta Region by SWP contractors, the CVP on behalf of the Project's contractors, or transfer of upstream CVP stored water would be done in these very wet water years.
c This is pumping of Delta surplus water and not purchased water.

The Fixed Purchase Alternative requires a water purchase of 185 TAF every year, with 35 TAF purchased from the Upstream from the Delta Region and 150 TAF purchased from the Export Service Area. Therefore, the total amount of assets available for taking fish actions in the Delta is 185 TAF plus variable operational assets. The fact that the amount of variable operational assets is unknown becomes a problem for the Fixed Purchase Alternative. Not knowing the total annual assets available makes it impossible to do the same type of analysis done for the Maximum Water Purchase and Typical Water Purchase Scenarios under the Flexible Water Purchase Alternative. What is known is that the amount of EWA assets available annually for the Fixed Water Purchase Alternative will be less than the assets available for both the Maximum Water Purchase and Typical Water Purchase Scenarios in most years. The result is the amount of fishery benefits provided by implementing the Fixed Purchase Alternative EWA fish actions in the Delta will be less than calculated for the two water purchase scenarios under the Flexible Purchase Alternative. Also the total amount of water to be exported from the Delta during the July through September period will be 35 TAF every year and that amount is significantly less than the amount of water exported in the Maximum Water Purchase and Typical Water Purchase Scenarios. Therefore, the negative effects of increasing exports during the summer months would be much less than those calculated for the two water purchase scenarios under the Flexible Purchase Alternative. The qualitative conclusion that can be made is that the Fixed Purchase Alternative will provide less environmental benefits than the benefits resulting from implementation of the Flexible Purchase Alternative.

However, given that the majority of benefits provided by the EWA Program occur within the Delta due to fish actions (Delta export reductions), the process described below was used in an effort to reasonably approximate salvage-related effects under the Fixed Purchase Alternative.

It was estimated in the CALFED ROD that the average annual variable operational asset would be 70 TAF (CALFED ROD page 58). For this analysis it is assumed that the available Fixed Purchase Alternative annual assets will total 255 TAF (185 + 70 = 255 TAF). Using the results from the Typical Water Purchase Scenario, the EWA benefits measured in reduced fish salvaged at the CVP and SWP pumping plants during the December through June period for the Fixed Purchase Alternative are calculated by multiplying the annual benefits during the December through June period under the Typical Water Purchase Scenario by 255 TAF and dividing it by the assets available or used in that year under the Typical Water Purchase Scenario (see column (2), Tables 15 through 19). This calculation does not allow the ratio to exceed 1.0. The increase in fish salvage due to increased export of EWA water purchased from the Upstream from the Delta Region during the July through September period for the Fixed Water Purchase Alternative were calculated in a similar manner using a ratio of 35 TAF divided by the amount of water exported under the Typical Water Purchase Scenario during that period (see column (3), Tables 15 through 19). The results of the analysis using the above process to calculate the overall, net EWA benefits under the Fixed Water Purchase Alternative are shown in Tables 15 through 19.

Column (2), Dec–June, of the Tables 15 through 19 shows the decrease in the number of fish salvaged under the Typical Water Purchase Scenario due to the reduction of available assets under the Fixed Purchase Alternative. Column (3), Jul-Sept, shows the decrease in the number of fish salvaged under the Typical Water Purchase Scenario during the July through the September period. Column (4) is the sum of the Columns (1) and (2). Column (5) is the total reduction in salvage calculated for the Typical Water Purchase Scenario (refer to Section 3.2.6.2). Column (6) is the reduction in fish salvage for the Fixed Water Purchase Alternative calculated by adding Column (4) and Column (5).

1993	334,970	-1,066,920	-731,950	310,131	-421,819
Total	3,007,200	-3,553,335	-546,135	-7,087,274	-7,633,409

The results verify the qualitative conclusion stated above related to the reduction in beneficial impacts under the Fixed Purchase Alternative in relation to the benefits provided under the Typical Water Purchase Scenario. The Typical Water Purchase Scenario has lower salvage estimates for all fish species except striped bass. Although the salvage reductions for the Fixed Purchase Alternative are less than the Typical Water Purchase Scenario, there is a net benefit in each year for each species analyzed under the Fixed Purchase Alternative. For striped bass, there are some years when implementation of the Fixed Purchase Alternative would not result in beneficial effects; however, the total fish salvage reduction for the entire study period would be 7,633,409 striped bass.

3.0 Sacramento-San Joaquin Delta – Fish Salvage/Benefit Analysis

The CVP and SWP facilities that pump water from the Delta can entrain and kill fish, some of which are Federally- and State-listed species. As described in Section 1, Introduction, of this document, the purpose of the EWA is to improve aquatic habitat conditions to protect and assist in the recovery of Delta-dependent fish species of concern through the management of EWA assets to reduce CVP/SWP Delta export pumping during periods critical to at-risk in-Delta fish species while also providing the CVP and SWP contractors and customers water supply reliability.

This section describes the methodology, assumptions, and results of the evaluation specifically developed to determine the potential benefits of implementing the EWA Flexible Purchase Alternative. This evaluation uses historical fish salvage data from the CVP and SWP pumping plants to evaluate the overall affect of 1) reducing Project exports on an annual basis, as determined appropriate during the months of December through June or July (EWA fish actions); and 2) changes in Delta exports (increased pumping) July through September to repay the Projects.

3.1 Salvage

Salvage is used as an indicator of fish loss resulting from SWP and CVP export operations from the south Delta. Salvage operations at the CVP and SWP export facilities (the John E. Skinner Fish Protection Facility and the Tracy Fish Collection Facility) are performed to reduce the number of fish adversely affected by entrainment (direct loss). Salvage estimates are defined as the number of fish entering a salvage facility and subsequently returned to the Delta through a trucking and release operation. Because survival of fish species sensitive to handling is believed to be low (delta smelt), increased salvage at these facilities is considered an adverse effect of an action or project upon fish resources.

3.2 Methodology

Salvage modeling was performed to develop an indication of the relative effect of the SWP and CVP pumping operations under the Baseline Condition and with implementation of the Flexible Purchase Alternative. The evaluation uses historical fish salvage data from the CVP and SWP pumping plants to quantify the effect of the Flexible Purchase Alternative upon specific fish species in the Delta.

3.2.1 Historical Data

Historical salvage records provide data for delta smelt, Chinook salmon, steelhead, splittail, and striped bass salvage for both the SWP and CVP facilities. These data were used to develop estimates of salvage loss. The salvage data prior to 1979 does not sufficiently identify the fish species salvaged to allow an estimate of benefits for the key species of concern. Since 1979 the salvage data provides daily densities, in numbers of fish salvage per 1,000 acre-feet pumped at the SWP Banks Pumping Plant and the CVP Tracy Pumping Plant, for Chinook salmon, steelhead, striped bass, Sacramento splittail, and delta smelt.

Data selected for use in these analyses extended over a 15-year period from 1979 to 1993. This period was selected based on consideration of the reliability of salvage data (e.g., accurate species identification, expansion calculations, etc.) and correspondence with the hydrologic model period used for the CALSIM II and related modeling applications that extends through 1993. This 15-year period also provides a range of water year conditions (e.g., wet, above normal, below normal, dry, and critical years).

3.2.2 Simulations/Assumptions

The CALSIM II study used for analyses in the EWA EIS/EIR provides an operational simulation of how the CVP and SWP would be operated if the historical hydrology were to repeat. The CALSIM II simulation encompasses the 1922 through 1993 period. Because usable historical salvage is only available beginning in 1979 and the last year of the CVP/SWP operational simulation is 1993, the study period for the Delta environmental effects analyses is necessarily 1979 to 1993.

Simulations are performed assuming 1) the 1979 through 1993 hydrologic period repeats; 2) the Projects are operated during this period utilizing the current system-wide water demand and regulatory requirements[4]; and 3) the historical fish salvage that occurred during this period would occur again. Further, as described in Section 2.2.1.1, the CALSIM II benchmark study includes 2001 LOD (demands, facilities, infrastructure) and water allocation/regulatory standards.

3.2.2.1 Baseline Condition

The Baseline Condition for the evaluation of Delta fish salvage is taken from the CALSIM II benchmark study and related post-processing tools used to create the "virtual" CALSIM II output database specifically for the 15-year period of record (1979 to 1993).

3.2.2.2 Flexible Purchase Alternative

The Flexible Purchase Alternative condition for the evaluation of Delta fish salvage is taken from the CALSIM II benchmark study as modified by post-processing applications to incorporate implementation of the EWA Program. Specifically, the 15-year period of record, 1979 to 1993 is used for the determination of EWA Program affects upon salvage.

As described in Section 2.2.2.2, EWA water asset acquisitions were examined under two different scenarios 1) Maximum Water Purchase Scenario; and 2) Typical Water Purchase Scenario.

3.2.3 Salvage Calculations

Calculations of salvage loss at the SWP and CVP, as a function of changes in the seasonal volume of water diverted, have been used as an indicator of potential effects resulting from changes in water project operations. The magnitude of direct losses resulting from export operations is a function of the magnitude of monthly water exports from each facility and the density (number per acre-foot) of fish vulnerable to entrainment at the facilities. Results of the hydrologic modeling performed for the Baseline Condition and the Flexible Purchase Alternative scenarios provide estimates of the average monthly Delta export operations for both the SWP and CVP. Salvage data are available on species-specific level at both the SWP and CVP

[4] CALSIM II assumptions and output.

facilities for use in estimating the risk of fishery loss. Average densities (number per acre-foot) were calculated monthly for both the SWP and CVP facilities for selected fish species over a 15-year period (1979 to 1993). Estimates of direct loss from SWP and CVP facilities were calculated for Chinook salmon, steelhead, delta smelt, splittail, and striped bass.

An index of salvage was developed for the purposes of evaluating the incremental effects of EWA operations on the direct losses at the Delta export facilities. The salvage index was derived using records of species-specific salvage data at the SWP and CVP to calculate average monthly density (number of fish per TAF), which could then be multiplied by the calculated SWP and CVP monthly exports (in TAF) obtained from the hydrologic modeling output. The salvage index was calculated separately for the SWP and CVP export operations under the Baseline Condition and Flexible Purchase Alternative. The resulting salvage index was then used to determine the incremental benefits (reduced salvage) and impacts (increased salvage) calculated to result from EWA operations.

Average monthly salvage densities for each species were calculated from daily salvage records over the period from 1979 through 2001 (R. Brown, unpublished data; CDFG, unpublished data). Based on the daily salvage, expanded for sub-sampling effort, a daily density estimate was calculated using the actual water volume diverted at each of the two export facilities. The daily density estimates were then averaged to calculate an average monthly density. For consistency, the average monthly density of each of the individual target species was then used to calculate the salvage index for the period from January 1979 through September 1993 using hydrologic modeling results for the Baseline Condition and Flexible Purchase Alternative. After calculating the monthly salvage index for each species, assuming EWA operations, the baseline estimate was subtracted from the monthly salvage index for each species to determine the net difference in salvage estimates (EWA operations - baseline estimate = net change) that are anticipated to occur with implementation of the Flexible Purchase Alternative. These calculations were performed for both the Maximum Water Purchase Scenario and the Typical Water Purchase Scenario.

3.2.4 Limitations

It is recognized that during the historical period, 1979 to 1993, the Projects were operated under Delta water quality, flow, and export constraint requirements that were much less stringent than the Delta requirements in place today. This suggests that the historical fish salvage was likely higher than it would be if the 1979 to 1993 period reoccurred with the Projects operated under today's Delta requirements, as assumed in this analysis. As a result, the Delta effects analyzed in this document likely will over-estimate the amount of EWA assets required to achieve the State and Federal fishery agencies' habitat conditions improvement goals.

The current populations of some of the listed species, such as winter-run Chinook salmon, are larger today than they were during the 1979 to 1993 period. Because of this, neither the timing, duration, nor the quantity of water needed for most operational curtailments can be accurately estimated until shortly before the action is scheduled. Differences in conditions between the historical 1979 to 1993 period and what would occur if that hydrologic period reoccurred today, indicate that the historical fish salvage at the Projects' pumping plants that occurred during the 1979 to 1993 period would not be the same today.

However, despite the inaccuracies within the analyses caused by assuming historical fish salvage at the pumping plants, the evaluations were performed to provide some approximate quantification of the overall potential EWA benefits that may be realized with implementation of the EWA program, using the best available data. Without some quantification, the discussion and analysis of benefits of the EWA and the cost of exporting water would have to be qualitative and based upon scientific opinion. Therefore, the results provided by the analyses must be considered as only part of the information (quantitative and qualitative) that should be used to evaluate the effects of implementing the EWA in the Delta.

3.2.5 Impact Analysis Comparisons

The results for the Maximum Water Purchase Scenario under the Flexible Purchase Alternative were compared to the Baseline Condition to determine the overall maximum net benefits that may result from implementation of the EWA program. These results are described in Section 3.2.6.1 and in Chapter 9 of the EWA EIS/EIR.

Additionally, the results for the Flexible Purchase Alternative, under the Typical Water Purchase Scenario were compared to the Baseline Condition to determine the overall, more likely, net benefits that may result from implementation of the EWA program. These results are described in Section 3.2.6.2 and in Chapter 9 of the EWA EIS/EIR.

3.2.6 Results

The results from the evaluation of each scenario, summarized in the following sections, indicate that implementation of the EWA fish actions would result in overall long-term net benefits to the fish species of concern in the Delta Region, relative to the Baseline Condition. A more detailed presentation of overall net benefits to the individual species is presented in Chapter 9 of the EWA EIS/EIR.

For the purposes of evaluating potential effects of the EWA program on fish salvage, the incremental difference in the annual salvage indices reflect the benefit (reduced salvage under the EWA Program) as a negative index and an incremental adverse impact (increased salvage under the EWA Program) as a positive index.

3.2.6.1 Maximum Water Purchase Scenario – EWA Benefits

The salvage modeling indicates that the Maximum Water Purchase Scenario would result in overall net benefits as determined by estimated reductions in salvage loss, as presented in Tables 20 through 34 for Chinook salmon, delta smelt, Sacramento splittail, striped bass, and steelhead. It is noted that the values provided in these tables indicate the maximum possible salvage benefits based on the assumptions for this scenario (described in Section 2.2.2.2). Therefore, these results represent an upper boundary for the level of benefit that could occur with implementation of the proposed EWA fish actions.

Three tables are shown for each species. The first table shows the salvage for the Baseline Condition, the second table is an intermediate step that shows the reduction in the base salvage after the assumed EWA pump reductions are implemented, and the third table shows the overall net result of the combined influences from the assumed EWA pump reductions and the increased summer Delta export pumping to repay SWP and CVP customers.

The EWA provides benefits to all fish species studied during the 1979 to 1993 study period. There are two years when the EWA does not result in a net decrease of salvage for listed species. However, it is noted that, in real-time operations, if fish species of concern were observed near the pumps, the Management Agencies could avoid impacts by delaying the start of summer export pumping until it is determined the fish are out of the area, or until the EWA fish action is completed.

3.2.6.2 Typical Water Purchase Scenario – EWA Benefits

The calculation of the EWA benefits for the Typical Water Purchase Scenario are shown in Tables 35 through 49 for delta smelt, steelhead, Chinook salmon, Sacramento splittail, and striped bass. Three tables are shown for each species. The first table shows the salvage under the Baseline Condition; the second table shows reduced base salvage after the assumed EWA pump reductions are implemented, and the third table shows the overall net affect on base salvage with the assumed EWA pump reduction and the increase in summer export pumping of the EWA assets. As indicated by these results for the analysis period, 1979 to 1993, the Typical Water Purchase Scenario would result in a net beneficial impact as measured by estimated annual net salvage data. These results indicate that the EWA provides net benefits to all fish species studied. Changes in salvage estimates are indicated for each year for each

species. Additional species-specific discussions of these results are provided in Chapter 9 of the EWA EIS/EIR.

4.0 Impact Assessment Approach for Non-Project Reservoirs

There are several non-Project reservoirs that could serve as potential water sources for the EWA. Because these non-Project reservoirs are not managed under the operations of either the CVP or SWP, they are not included in the modeling simulations described above. As such, another method of evaluating the potential effects from EWA actions was developed to analyze possible EWA-related effects on these non-Project reservoirs.

4.1 Assumptions for Non-Project Reservoirs

The following assumptions have been established with regard to the status and operation of the non-Project reservoirs. These assumptions were applied to the analysis for each of the non-Project reservoirs where the EWA could purchase water (see Chapter 2 of the EWA EIS/EIR).

- Non-project reservoir operations will continue to function under the same set of demands and assumptions that have previously been employed by each system in earlier years, including reservoir drawdown to targeted storage levels.

- Analysis relating to the timing, magnitude, and duration of water transport activities and their potential impacts on riverine flow processes will be developed using a monthly time-step, culminating at the end of the water year in late-September. Where applicable, the period of time that will be used to evaluate resource-specific impacts (e.g., fisheries, vegetation and wildlife) will concur with the timeframe associated with potential asset transfers, as identified in the modeling output.

- EWA asset availability from non-Project reservoirs and any associated potential impacts will be evaluated by reviewing hydrologic data and reservoir specific area-capacity curves to predict changes in surface water elevation and reservoir refill frequencies. This information will provide an indication of the target storage capacities, minimum pool volume, and range of surface water elevations under normal operating conditions, and the probability of annual refill for each reservoir. Estimations for flow changes will be translated into relative changes in surface water elevations and will be used to evaluate resource specific impacts.

Limitations have been placed on the maximum volume of water potentially available to EWA from each non-project reservoir, based upon reservoir size, operational constraints and the existing refill patterns within each basin. Additionally, EWA asset acquisitions must not result in a reduction of reservoir surface water elevation beyond the minimum reservoir drawdown levels as stated in the corresponding FERC license, where applicable. This documentation and any related materials would also be reviewed to ensure compliance with all appropriate regulatory requirements.

The following discussion describes how EWA actions are expected to utilize and influence storage capacities of the non-Project reservoirs. This discussion serves as a description of the most utilitarian implementation of non-project reservoir water supplies that could be used as potential EWA assets. It is intended to provide the set of conditions describing the relationships between each non-project reservoir and the Flexible Purchase Alternative, as applied in all resource-specific impact analyses.

4.1.1 Placer County Water Agency (PCWA) Non-Project Reservoirs

EWA assets may be acquired from two reservoirs under PCWA's management, French Meadows and Hell Hole Reservoirs. PCWA's ability to sell water to EWA is also dependent upon PG&E objectives and operations. The decision to sell water to the EWA is dependent upon two factors: 1) the normal combined operational drawdown level (typically 150 TAF) that is maintained for both reservoirs; and 2) FERC minimum requirements for combined carryover storage, which are stated as 50 TAF.

When available, EWA would only purchase 20 TAF annually from PCWA, with the assumption that reservoirs would be refilled on an annual basis. Under the most severe conditions, refill may not occur. In that event, 20 TAF may be purchased within two sequential years for a total asset acquisition of 40 TAF. With regard to French Meadows and Hell Hole Reservoirs, if both reservoirs had a combined water debt of 40 TAF, EWA would not purchase additional water

from PCWA until all or part of the 40 TAF was replenished. If only a portion of the 40 TAF were refilled, any new EWA acquisition that could be purchased would only be up to the volume of water refilled, not to exceed the original total of 40 TAF. Imposing a limit of a 40 TAF total reduction on EWA asset availability also serves as a conservation measure to ensure that reservoir storage is not depleted below historic levels.

4.1.2 Oroville-Wyandotte Irrigation District (OWID) Non-Project Reservoirs

Under normal operating conditions, combined winter baseline storage during November and December is around 60 TAF in Little Grass Valley and Sly Creek Reservoirs, with approximately 80 percent of storage (48 TAF) in Little Grass Valley Reservoir and 20 percent of storage (12 TAF) in Sly Creek Reservoir. Minimum reservoir storage for each water body is set at 500 AF, according to FERC requirements. There are refill criteria for this system. Although the reservoirs refill annually, a debt to the SWP could occur if the stored water could have been utilized by the SWP absent the EWA acquisition. OWID may have up to 15 TAF of water assets available to EWA from Little Grass Valley and Sly Creek Reservoirs.

4.1.3 Yuba County Water Agency (YCWA) Non-Project Reservoirs

YCWA may be able to provide EWA with up to 100 TAF of stored water from New Bullards Bar Reservoir. YCWA could sell stored reservoir water to the EWA as long as local needs, instream flows, and system demand requirements were met. This action would result in a reduction in the volume of stored water in New Bullards Bar Reservoir and would cause a decrease in surface water elevation of approximately 29 feet. Under the minimum surface water utilization scenario, New Bullards Bar Reservoir storage would be decreased by 30 TAF, thereby providing EWA with up to 30 TAF in asset acquisitions by the end of September.

Unlike the other non-Project reservoirs operated by PCWA and OWID, there is a possibility that YCWA transfers could result in an impact caused by changes in downstream operations. Depending upon Delta conditions and the effect of the transfer on Lake Oroville, there may be a need to increase releases from Lake Oroville in order to compensate for the reduced flows into the Delta during periods of time when New Bullards Bar Reservoir is being refilled upstream. Under these conditions, Oroville Reservoir operations may need to be altered to accommodate downstream demands in the Delta. While Lake Oroville surface water elevations would remain within the range of targeted storage levels, the operational response associated with releasing additional water might be regarded as a change in project operations. This response might be considered a result indirectly arising from EWA actions.

5.0 Project Hydropower Production and Pumping Loads

Chapter 16 of the EWA EIS/EIR presents an evaluation of power impacts that may result from implementation of the EWA Program. Power impacts were assessed using the LongTermGen Model, which is a CVP power model developed to estimate the CVP power generation, capacity, and project use based on the operations defined by a CALSIM II simulation. The model is a Microsoft Excel 2000 spreadsheet with extensive Visual Basic programming.

The LongTermGen Model computes monthly generation, capacity, and project use for each month of the CALSIM II simulation. Generation and capacity are not diminished by the EWA, only altered by the timing of production. Thus quantitative comparisons of generation were not performed.

Pumping of EWA water is a cost that will be assumed by the program. This cost is manifest both in the additional energy to pump the water and in the temporal value of energy moved between months. Information on the effects of EWA actions on pumping at Banks, Tracy and O'Neill pumping plants were calculated using a plant efficiency of 298 KWh/AF times the volume of water pumped at each facility. A discussion of the economic affects of temporal changes to pumping is included in Chapter 16.

6.0 Impact Analysis for Planning (IMPLAN) Economic Model

The EWA EIS/EIR provides a regional economic impact analysis developed through use of a regional input-output (I-O) model. I-O models analyze the relationships between various sectors of the economy through simulating how a change in one sector impacts the remainder of the system. In agricultural economics, I-O models often are used to examine the economic relationship between agricultural sectors, such as crops and livestock, and other sectors of the economy, such as manufacturing, services and retail trade. The specific I-O model used for the economic analysis was "Impact Analysis for Planning" (IMPLAN), developed by the University of Minnesota and owned by the Minnesota IMPLAN Group. The IMPLAN database includes 21 economic and demographic variables for 528 sectors covering every county in the United States. The data are taken from numerous State and Federal published sources. At least three limitations exist in I-O models:

- A simple application of I-O presumes that all inputs change with output according to their pre-existing average expenditure shares. The pattern of expenditure changes caused by land idling is the same as the pre-existing average. Economic theory suggests that farm expenditure does not decrease by an amount equal to the loss of crop sales, because the water transfer is temporary.

- I-O analysis includes only backward linkages. Forward linkages, economic effects from transportation, marketing, and processing of farm products, are not counted when the I-O model input is value of farm output.

- The readily available I-O models, including IMPLAN, use county level final demand and employment data with a national average technology matrix. This technology matrix may therefore not be representative of California conditions.

Modifications were made to the economic model to correct for these limitations. Expenditure data from the University of California Cooperative Extension (UCCE) were used to correct for two of the aforementioned limitations. These expenditure data, not the value of crop production, were input to the I-O model. Second, the UCCE data were incorporated into the model to more accurately represent the expenditure patterns for idled crops in the EWA Program area than the national average technical coefficients in IMPLAN. The use of UCCE crop budgets means the "first round" expenditure effects should be more accurate. The inaccuracy created by national average coefficients in second and subsequent rounds of regional expenditure still remain. Lastly, forward linkages were added to the I-O model. These linkages are included through considering the expenditure patterns of forward linked industries for transportation, storage, and rice milling.

Several economic assumptions are implicit in I-O analysis and were not considered by the analysis. These include no substitution of inputs (ratio of input used in production are fixed), constant returns to scale (the amount of production increases by about the same per unit of input regardless of initial amount of input), and fixed prices (prices do not change as quantity of demand changes).

Output reported by IMPLAN includes changes in total value of output, wages and salaries, value added, and number of jobs in each economic sector analyzed from land idling.

1. INTRODUCTION

The CALFED Bay-Delta Program is an unprecedented effort to build a framework for managing California's most precious natural resource: water. California and the Federal government in partnership, are launching the largest, most comprehensive water management program in the world. This is the most complex and extensive ecosystem restoration project ever proposed. It is also one of the most intensive water conservation efforts ever attempted. It is the most far-reaching effort to improve the drinking water quality of millions of Californians as well as an unprecedented commitment to watershed restoration. And it is the most significant investment in storage and conveyance in decades. This document is the Record of Decision (ROD) for addressing these efforts through a sustained, long-term effort by the CALFED Agencies and stakeholder groups.

The CALFED Bay-Delta Program began in May 1995 to address the complex issues that surround the Bay-Delta. The CALFED Bay-Delta Program is a cooperative, interagency effort of 18 State and Federal agencies with management or regulatory responsibilities for the Bay-Delta. The CALFED Program is a collaborative effort including representatives of agricultural, urban, environmental, fishery, and business interests, Indian tribes and rural counties who have contributed to the process.

The San Francisco Bay/Sacramento-San Joaquin Delta (Bay-Delta) estuary is the largest estuary on the West Coast. It is a maze of tributaries, sloughs, and islands and a haven for plants and wildlife,

supporting over 750 plant and animal species. The Bay-Delta includes over 738,000 acres in five counties. The Bay-Delta is critical to California's economy, supplying drinking water for two-thirds of Californians and irrigation water for over 7 million acres of the most highly productive agricultural land in the world.

The Bay-Delta is also the hub of California's two largest water distribution systems - the Central Valley Project (CVP) operated by the U.S. Bureau of Reclamation (Reclamation) and the State Water Project (SWP) operated by the California Department of Water Resources (DWR). Together, these water development projects divert about 20 to 70 percent of the natural flow in the system depending on the amount of runoff available in a given year.

These diversions, along with the effects of increased population pressures throughout California, exotic species, water pollution, and numerous other factors have had a serious impact on the fish and wildlife resources in the Bay-Delta estuary. The drought of 1987-92 demonstrated just how vulnerable California is to water shortages. More recent conflicts between water quality, fish protection and water supply also demonstrate how little flexibility there is in the current system. With the State's population expected to grow from 34 million today to 59 million in 2040, the need to conserve, to build our capacity, and to manage our water system more efficiently is no longer just a goal, it is a reality.

Before CALFED, all agreed on the importance of the Bay-Delta estuary for both fish and wildlife habitat and as a reliable source of water, but few agreed on how to manage and protect this valuable resource. The CALFED Bay-Delta Program was established to develop a long-term comprehensive plan that will restore ecological health and improve water management for beneficial uses of the Bay-Delta system. Over the last five years, hundreds of individuals have spent thousands of hours discussing and debating options for a long-term restoration and management plan for the Bay-Delta estuary. The task is fourfold: 1) to restore the ecological health of a fragile and depleted Bay-Delta estuary; 2) improve the water supply reliability for the State's farms and growing cities that draw water from the Delta and its tributaries, including 7 million acres of the world's most productive farmland; 3) protect the drinking water quality of the 22 million Californians who rely on the Delta for their supplies; and 4) protect the Delta levees that ensure its integrity as a conveyance and ecosystem. Through the Bay-Delta Advisory Council,

State and Federal agencies have worked with stakeholders and the public to shape these options into this framework for a comprehensive plan.

The CALFED Program and the CALFED Agencies have approached many ecosystem and water management issues from a regional perspective: what makes the most sense for the affected region. The regions, which include their respective watersheds, are the Sacramento Valley, the San Francisco Bay Area, the Delta, Westside San Joaquin Valley, San Joaquin River/South San Joaquin Valley, and Southern California. Although each region raises unique ecosystem and water management issues, each region's issues affect the health and function of the Bay-Delta system as a whole. Those regional issues nevertheless need regional solutions that contribute to overcoming the challenges facing the Bay-Delta system. In crafting regional solutions, the CALFED Program has also identified and considered the other, independent actions taken by Federal, State and local agencies operating outside the CALFED Program. In addition, CALFED has taken into account its obligations to comply with ongoing commitments, such as the commitments included in the State's area of origin laws.

Consistent with the stated purposes of the CALFED Bay-Delta Program since its outset in 1995, it is not the intent of this program to address or solve all of the water supply problems in California. The CALFED Program is directly or indirectly tied to a number of specific project proposals that would help toward meeting California's water needs for a wide variety of beneficial uses. CALFED is an important piece of a much larger picture that is the continuing responsibility of local, regional, State and Federal jurisdictions.

1.1 Overview

Following issuance of the Record of Decision, CALFED Agencies will proceed to Stage 1 implementation. Stage 1 covers the first seven years of a 30-year program and builds the foundation for long-term actions. This document sets out actions included in the Preferred Program Alternative for implementing Stage 1. These actions also depend upon subsequent project-specific environmental analyses as well as on subsequent review of financial and legislative proposals in this document by the State and Federal executive branches, Congress and the State Legislature.

The program components are as follows:

- Governance
- Ecosystem Restoration
- Watersheds
- Water Supply Reliability
- Storage
- Conveyance
- Environmental Water Account

- Water Use Efficiency (conservation and recycling)
- Water Quality
- Water Transfers
- Levees
- Science

These program components were recently described in the document entitled *California's Water Future: A Framework for Action*, issued on June 9, 2000. The document is referred to as "the Framework" in other locations in this ROD.

All aspects of the CALFED Program are interrelated and interdependent. Ecosystem restoration is dependent upon water supply and conservation. Water supply depends upon water use efficiency and consistency in regulation. Water quality depends upon improved conveyance, levee stability and healthy watersheds. The success of all of the elements depends upon expanded and more strategically managed storage.

California taxpayers, stakeholders and the Federal government will be called upon to invest billions of dollars over the next decade on CALFED programs. Expenditure of those funds must be based upon accountability and measurable progress being made on all elements of the Program. The project schedules described in this ROD depend upon certain assumptions about State and Federal budgets, optimized construction schedules, willing sellers, and other contingencies. These assumptions may change as the CALFED Program progresses and appropriate revisions to the Program may be necessary. Consistent with Federal law, nothing in this ROD constrains the discretion of the President or his successors to make whatever budgetary or legislative proposals he or his successors deem appropriate or desirable. The commitments of the United States and of the State of California under this ROD are necessarily contingent upon the availability of appropriated funds or upon enactment of authorizing legislation providing other sources of funding.

During implementation, the Program will incorporate both a high level of stakeholder participation and, as a central feature, science-based adaptive management. The Program includes a strong commitment to assure that its decisions and actions are based on sound science. To this end, the Program provides for comprehensive monitoring and data collection, and continuous and comprehensive scientific review of actions and decisions. The highest quality and credibility of science-based decision making will be assured by the integration in the Program of an independent board of scientific experts. In addition, the Program has hired a nationally-recognized scientist to coordinate the science effort, including related scientific studies conducted by CALFED Agencies.

Consistent with Proposition 204, prior to November 15, 2001 and each year thereafter, the CALFED Policy Group or its successor, in consultation with other interested persons and agencies, will review the CALFED Program's progress in meeting the implementation schedule in this ROD. The CALFED Policy Group or its successor will submit an annual report by December 15th to the Governor, the Secretary of the Interior, the State Legislature and the Congress that describes the status of implementation of all elements of the Program. The report will describe the status of all Stage 1 actions, including goals, schedules and financing agreements, taken to meet

CALFED objectives in the following areas:

- Completion of key projects and milestones identified in the Ecosystem Restoration Program.
- Development and implementation of local programs for watershed conservation and restoration.
- Progress in improving water supply reliability and implementing the Environmental Water Account (see section 2.2.7 for Environmental Water Account).
- Achievement of commitments under State and Federal Endangered Species Acts.
- Implementation of a comprehensive science program.
- Progress on storage projects, conveyance improvements, levee improvements, water quality projects, and water use efficiency programs.
- Progress toward acquisition of the State and Federal permits, including Clean Water Act Section 404 permits, for implementation of projects in all identified program areas.
- Progress in achieving benefits in all geographic regions covered by the Program.
- Legislative action on water transfer, groundwater management, water use efficiency and governance issues.
- Status of complementary actions.
- Status of mitigation measures.
- Revisions to funding commitments and program responsibilities.

If at the conclusion of each annual review, or if a timely annual review has not been issued, the Governor or the Secretary of the Interior determines that the schedule or objectives established in this ROD has not been substantially adhered to, the Governor and the Secretary, after notice to, and consultation with, State and Federal CALFED representatives, will prepare a revised schedule that ensures achievement of balanced solutions in all program areas consistent with the intent of this ROD and applicable regulatory compliance documents. Upon determination that the prior schedule has not been substantially adhered to, State funds, if the determination was made by the Governor, and Federal CALFED funds, if the determination was made by the Secretary of the Interior, will to the extent authorized be available for expenditure in the subsequent budget year only if a revised schedule has been developed within six months from the date on which the determination was made. Upon the submission of any revised schedule, funds will be expended in accordance with that revised schedule.

1.2 Purposes of This Record of Decision

This Record of Decision for the CALFED Bay-Delta Final Programmatic Environmental Impact Statement and Report (EIS/EIR) represents the culmination of the National Environmental Policy Act (NEPA) and the California Environmental Quality Act (CEQA) processes. The ROD reflects a final selection of a long-term plan (Preferred Program Alternative), which includes specific actions, to fix the Bay-Delta, describes a strategy for implementing the plan, and identifies complementary actions the CALFED Agencies will also pursue.

For actions contained within the Preferred Program Alternative that are undertaken by a CALFED Agency or funded with money designated for meeting CALFED purposes, environmental review will tier from the Final Programmatic EIS/EIR. These actions will be carried out in a manner consistent with this ROD and incorporate the mitigation strategies contained in Appendix A to this ROD.

The Preferred Program Alternative is a set of programmatic actions, studies, and conditional decisions. It includes the broadly described actions that set the long-term overall direction of the Program. The description of the alternative is programmatic in nature, intended to help agencies and the public make decisions on the broad methods to meet program purposes. The Preferred Program Alternative description is an important legal element of compliance with CEQA and NEPA. The Preferred Program Alternative is not intended to define the site specific actions that will ultimately be implemented.

Whenever a broad environmental impact analysis has been prepared and a subsequent narrower analysis is then prepared on an action included within the entire program or policy, the subsequent analysis need only summarize the issues discussed in the broader analysis and incorporate discussions from the broader analysis by reference. This is known as tiering. Tiered documents focus on issues specific to the subsequent action and rely on the analysis of issues already decided in the broader programmatic review. Absent new information or substantially changed circumstances, documents tiering from the CALFED Final Programmatic EIS/EIR will not revisit the alternatives that were considered alongside CALFED's Preferred Program Alternative nor will they revisit alternatives that were rejected during CALFED's alternative development process.

Within the defined CALFED solution area, individual CALFED Agencies will implement actions that are part of CALFED's Preferred Program Alternative and will develop identified complementary actions, not part of the CALFED Program, which will help achieve CALFED goals and objectives. All actions will be subject to appropriate environmental review. Many of the complementary actions are not included in the CALFED Program because they were already underway when the CALFED effort was started in 1995. In those cases, CALFED programmatic actions have been designed to complement or supplement these existing actions and programs. Other actions will continue to be developed by individual CALFED Agencies over time. Because these new actions and programs are outside the programmatic analysis of impacts that CALFED has prepared, they are not the subject of final decision in this ROD. Implementation of all individual actions within the Preferred Program Alternative, complementary actions and new actions will be predicated on the appropriate level of environmental review, documentation and permitting.

In addition, many activities will be undertaken within the CALFED solution area by non-CALFED Agencies. By certifying the ROD, the CALFED Agencies do not intend to preclude implementation of projects not expressly evaluated in the CALFED Final Programmatic EIS/EIR. Nor do the CALFED Agencies intend to affect the ability of local communities to meet their individual water supply needs. Finally, nothing in this ROD is intended to, nor does, affect the regulatory responsibilities of individual CALFED Agencies.

This ROD recognizes that the CALFED Agencies have specific statutory and/or regulatory

authority and responsibilities, and that actions of these agencies must be consistent with applicable procedural and substantive requirements. Nothing in this ROD is intended to or shall have the effect of constraining or limiting any public entity in carrying out its statutory responsibilities. Nothing in this ROD constitutes an admission by any party as to the proper interpretation of any provision of law; nor is anything in this ROD intended to, nor shall it have the effect, of waiving or limiting any public entity's rights and remedies under any applicable law. Additionally, this document in no way supersedes the requirements of Executive Order 12322 or other Federal water policies and authorities.

The CALFED Agencies recognize that certain departments, boards, and commissions have adjudicative responsibilities with respect to contested matters that are brought before them. Such responsibilities include the requirement that the adjudicative entity and its members avoid bias, prejudice, or interest in the adjudicative matters before them; e.g., they cannot decide, before completion of any required hearing or equivalent proceeding, the outcome of a matter. Some such adjudicative entities exist within the undersigned CALFED Agencies. This ROD does not in any way require or commit an adjudicative entity to participate in proposing a project that will come before it for approval. Under this ROD, the role of adjudicative entities in connection with matters that may require an adjudicative decision is limited to promptly and diligently processing any applications, petitions, or other requests for approval. Nothing in this ROD commits an adjudicative entity to an approval or disapproval of any project subject to the authority of the adjudicative entity, nor to a term or condition in any approval of a project by the adjudicative entity.

1.3 Background/Historical Context

1.3.1 Bay-Delta Accord

Seeking solutions to the resource problems in the Bay-Delta, State and Federal agencies signed an agreement in June 1994 to (1) coordinate their actions to meet water quality standards to protect the Bay-Delta estuary; (2) coordinate the operation of the State Water Project (SWP); and the Central Valley Project (CVP) more closely with recent environmental mandates; and (3) develop a process to establish a long-term Bay-Delta solution to address four categories of problems; ecosystem quality, water quality, water supply reliability, and levee system vulnerability.

This agreement laid the foundation for the Bay-Delta Accord and CALFED. The Accord, formally called the Principles for Agreement on Bay-Delta Standards between the State of California and the Federal Government, detailed interim measures for both environmental protection and regulatory stability in the Bay-Delta. On December 15, 1994, the Accord was signed by State and Federal resource agencies, as well as by stakeholders representing many local water agencies and environmental organizations. Under the terms of a December 1999 extension, the Accord formally expires when this ROD is executed. Thereafter, the provisions in the Accord are replaced in their entirety by the provisions and agreements in this ROD and associated documents.

1.3.2 Mission Statement

Early in the Program development, CALFED Agencies developed and adopted the mission statement, objectives and solution principles to guide how the Program will be implemented. The mission statement, objectives and solution principles are shown in the following box. CALFED used these to shape the alternatives and will continue to use these objectives and principles as actions are implemented. Carrying out the mission, achieving the objectives, and adhering to the solution principles will ensure that CALFED fulfills its commitment to continuous improvement in all of the four problem areas.

MISSION STATEMENT

The mission of the CALFED Bay-Delta Program is to develop a long-term comprehensive plan that will restore ecological health and improve water management for beneficial uses of the Bay-Delta system.

OBJECTIVES

CALFED developed the following objectives for a solution:

- Provide good water quality for all beneficial uses.
- Improve and increase aquatic and terrestrial habitats and improve ecological functions in the Bay-Delta to support sustainable populations of diverse and valuable plant and animal species.
- Reduce the mismatch between Bay-Delta water supplies and current and projected beneficial uses dependent on the Bay-Delta system.
- Reduce the risk to land use and associated economic activities, water supply, infrastructure and the ecosystem from catastrophic breaching of Delta levees.

SOLUTION PRINCIPLES

In addition, any CALFED solution must satisfy the following **solution principles**:

- ***Reduce Conflicts in the System*** Solutions will reduce major conflicts among beneficial uses of water.

- ***Be Equitable*** Solutions will focus on solving problems in all problem areas. Improvements for some problems will not be made without corresponding improvements for other problems.

- ***Be Affordable*** Solutions will be implementable and maintainable within the foreseeable resources of the Program and stakeholders.

- ***Be Durable*** Solutions will have political and economic staying power and will sustain the resources they were designed to protect and enhance.

- ***Be Implementable*** Solutions will have broad public acceptance and legal feasibility, and will be timely and relatively simple to implement compared with other alternatives.

- ***Have No Significant Redirected Impacts*** Solutions will not solve problems in the Bay-Delta system by redirecting significant negative impacts, when viewed in their entirety, within the Bay-Delta or to other regions of California.

1.3.3 Four Interrelated Program Objectives

The CALFED Program takes a broad approach to addressing the four problem areas of water quality, ecosystem quality, water supply reliability and levee system integrity, recognizing that many of the problems and solutions in the Bay-Delta system are interrelated. Problems in any one program area cannot be solved effectively without addressing problems in all four areas at once. This greatly increases the scope of efforts but will ultimately result in progress toward a lasting solution.

Thus, the single most important difference between the CALFED Bay-Delta Program and past efforts to solve the problems of the Bay-Delta is the comprehensive nature of CALFED's interrelated resource management strategies. A comprehensive CALFED solution will also be supported by governance mechanisms that overcome problem-specific or resource-specific limitations of previous, more narrowly focused, approaches.

1.3.4 Summary of Process

There are three phases to the CALFED Bay-Delta Program:

Phase I - In Phase I, completed in September 1996, CALFED identified the problems confronting the Bay-Delta, developed the mission statement and guiding principles, and devised three preliminary categories of solutions for Delta water conveyance. In addition, CALFED identified three preliminary alternatives, representing differing approaches to conveying water through the Delta, to be further analyzed in Phase II.

Phase II - In Phase II, CALFED has completed the Final Programmatic EIS/EIR and issued this ROD. This includes development of the Preferred Program Alternative and development of the Plan of Action (see Section 2.2) focusing on the first seven years (Stage 1) following issuance of this ROD.

Phase III - Implementation will begin in Phase III. This period will include project-specific environmental review and permitting, as necessary.

During Phase I, CALFED held scoping meetings, technical workshops, public information meetings, and public BDAC workgroup meetings. The commitment to active public involvement continued through Phase II with additional public meetings, presentations before interested groups, media outreach, special mailings of newsletters, regularly updated information on the Program's web site, and a toll-free public information telephone line.

2. DECISION

2.1 National Environmental Policy Act/California Environmental Quality Act Decision

After reviewing the alternatives discussed in the Final Programmatic EIS/EIR and their predicted environmental, economic and social consequences, the CALFED Agencies select the Preferred Program Alternative as the best alternative for meeting the Program purposes. The Preferred Program Alternative provides a long-term plan to improve water quality, stabilize Delta levees, restore the ecosystem and provide water supply reliability.

The alternatives considered in CALFED's Programmatic EIS/EIR represent a reasonable range of alternatives for meeting the program purposes. The Preferred Program Alternative includes a set of broadly described programmatic actions in eight program areas (see Section 2.1.3).

2.1.1 Discussion of Alternative Selection Process

In Phase I, CALFED initiated a lengthy, inclusive public process to develop alternatives in order to accomplish its mission. The Phase I process developed alternatives in six steps: identify problems, define objectives, identify actions, develop solution strategies, assemble alternatives, and refine alternatives. Early in Phase I, the Program identified 50 categories of actions to resolve Bay-Delta problems and achieve Program objectives. These action categories were drawn from existing literature and participation from CALFED agencies, the Bay Delta Advisory Council, and numerous workshops with stakeholders and the general public. Within these categories, hundreds of individual actions were defined. The action categories represent the building blocks of the alternatives. In other words, each alternative is a combination of action categories reflecting differing approaches to achieving Program objectives and addressing solution principles.

As a way to manage the number of alternatives while still representing the full range of approaches to resolving problems, CALFED focused on the critical conflicts in the Bay-Delta system to help define an initial set of alternatives. These conflicts included the relationships between:

- Fisheries and diversions
- Habitat and land use and flood protection
- Water supply availability and beneficial uses
- Water quality and land use

Approximately 100 initial alternatives resulted from this focus. The initial alternatives varied in the level of effort applied to actions related to water use efficiency, water quality, ecosystem quality, and levee system integrity components.

Following evaluations and comments received at public meetings, workshops, and in writing, CALFED reached a number of conclusions regarding the makeup of each alternative:

The best possible source water quality is of paramount importance to urban water supplies. Agencies that deliver drinking water were very concerned about the cost of meeting future drinking water quality standards, as well as the technical challenges associated with treating source water of degraded quality. This suggests strong pollutant source control measures in every alternative.

Delta levees will be needed to protect agriculture, infrastructure, and habitat no matter how water is conveyed in the Delta. Delta levees protect many valuable features, including farms, habitat, infrastructure, and Delta water quality. Even if a new conveyance facility is built that protects water quality for some export users, adequate levee integrity will still be required to protect water quality, facilities and property in the Delta. This argues for a similar level of Delta levee protection in each alternative.

Ecosystem actions in the Program needs a single coherent vision of ecosystem restoration. The restoration of ecosystem functions and the recovery of Bay-Delta species likely will require diverse actions that will be extensive in scope. There is really no alternative to a single comprehensive plan for restoring ecosystem health. Adaptive management will be vital in guiding efforts to improve ecosystem quality. It is this adaptive management that will provide the needed flexibility in the Ecosystem Restoration Program.

Water use efficiency must be strongly pursued in all the alternatives. Water use efficiency will maximize use of existing supply to meet all needs and reduce the need for new storage. This suggests that water use efficiency measures should be implemented at a substantially increased level among all the alternatives.

The Program then refined the alternatives, which led to selection of a set of Phase II alternatives that was large enough to offer a reasonable range of solutions while small enough to allow for detailed analysis. Three basic alternative approaches developed in Phase I of the Program were carried into Phase II. Seventeen alternative configurations of the three basic alternative approaches were developed to further explore potential refinements for storage and conveyance in Phase II. Of the seventeen configurations, five were eliminated from further evaluation, and the environmental consequences of twelve of these were evaluated in the March 1998 Draft Programmatic EIS/EIR.

Based on public and agency comments on the March 1998 Draft Programmatic EIS/EIR and additional technical analysis, the Program was able to further refine and narrow the number of alternative solutions to the four evaluated in the July 2000 Final Programmatic EIS/EIR. Reasons for the elimination or consolidation of alternatives included technical deficiencies, creation of conditions damaging to the aquatic environment, higher costs relative to similarly performing

alternatives, and the lack of a south Delta conveyance improvement element. The Program has determined that the Program objectives cannot be met without some south Delta conveyance improvements.

The four alternatives evaluated in the Final PEIS/EIR, Alternatives 1, 2 and 3 and the Preferred Program Alternative, vary primarily in their approach to water conveyance. Three basic alternative approaches were formed around different configurations of Delta conveyance: existing system conveyance, modified through-Delta conveyance, and dual-Delta conveyance. Each approach includes the same set of actions for water use efficiency, water quality, levee system integrity, ecosystem quality, water transfers, and watersheds. A range of storage options was evaluated for each alternative to support these programs and the Delta conveyance, and to seek a balance between attainment of Program objectives and cost effectiveness. For further discussion of these alternatives and the No Action Alternative and a comparison of each of the alternatives to the Preferred Program Alternative see section 2.1.4 below.

A detailed description of the program alternative selection process can be found in Section 1.4 and Response to Comment document of the Final Programmatic EIS/EIR.

2.1.2 Public Comments

Comments Received on June 1999 Draft EIS/EIR

CALFED received and considered a wide variety of comments on the June 1999 Draft Programmatic EIS/EIR. The comments included:

- Approximately 1,500 letters from individuals and organizations.
- Approximately 800 individuals testified at one or more of sixteen hearings held around the State.
- Approximately 2,400 pre-printed letters or postcards.

A total of approximately 11,000 individual comments were identified from these sources. CALFED Agencies prepared responses as part of the Final Programmatic EIS/EIR. A large percentage of the comments were general in nature and did not identify specific items from the Draft Programmatic EIS/EIR. Specific comments were categorized into 23 different areas of interest. Comments and responses can be found in the three volumes of the Response to Comments contained in the Final Programmatic EIS/EIR.

Comments Received on Final Programmatic EIS/EIR

Copies of the Final Programmatic EIS/EIR, including the responses to comments on the draft Programmatic EIS/EIR, were sent to all persons and public agencies who commented on the June 1999 Draft Programmatic EIS/EIR. As of August 28, 2000, CALFED received 411 letters on the Final Programmatic EIS/EIR. The decision makers have reviewed all of the letters commenting on the Final Programmatic EIS/EIR and considered this information as part of the process of preparing the ROD.

Many of the comments have been addressed in this ROD. For instance, the ROD addresses East Bay Municipal Utility District's comment on the source water for the Bay Area Blending Project and clearly articulates the CALFED Agencies' commitment that satisfactory resolution of fishery concerns is a prerequisite to implementation of a new Sacramento River diversion facility. The ROD also addresses the comment of Contra Costa Water District on implementation of Veale and Byron Tract projects in the South Delta. These are just a few examples of comments that have been addressed in the ROD.

Many comments repeat public comments on the Draft EIS/EIR that were addressed as part of the Response to Comments document in the Final Programmatic EIS/EIR. These included comments suggesting that the CALFED Program will forego or inappropriately influence existing regulatory processes. Several of the comments, similar to comments on the Draft EIS/EIR, reflect uncertainty/apprehension about the nature of some program element actions. As indicated in the Response to Comments document, these issues will be resolved as CALFED works with various stakeholders, agencies and local groups to further develop and implement the program element actions.

Several commenters asked for more time to provide additional comments on the Final Programmatic EIS/EIR and asked CALFED to hold a series of public hearings on the CALFED Program. The CALFED Agencies have accepted public comments on the Final Programmatic EIS/EIR from the date the Final Programmatic EIS/EIR was released to the public. This period will not be extended because of the desire to move forward into the project-specific implementation phase of the CALFED Program. Implementation of project-specific actions will involve additional environmental review as well as public involvement in the development of projects.

Many of the comments are project-specific; as such are beyond the level of detail of the Programmatic EIS/EIR and are not appropriate for a decision at this time. However, the concepts associated with the majority of the specific comments have been addressed in the Final Programmatic EIS/EIR and this ROD.

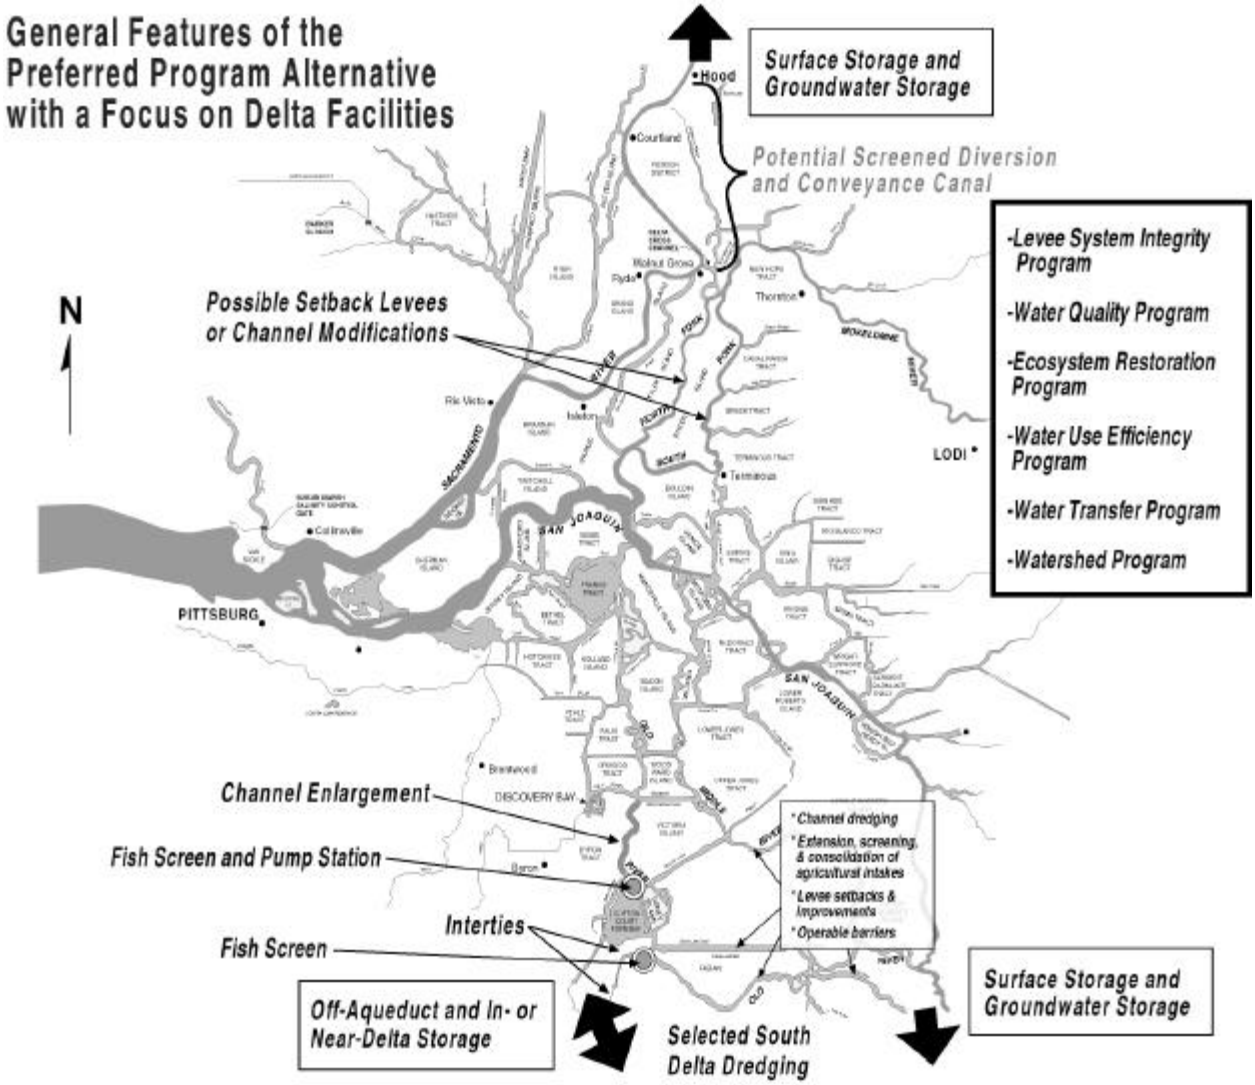
Comments indicated that local or directly affected individuals have not been given an adequate representation in the process and should be given opportunity to participate in all actions and shape decisions. The CALFED Program has been a collaborative effort. Public and agency involvement through outreach and education has been a focus of the CALFED Program since its

initial stages. These efforts have helped shape the CALFED Program, as well as develop the Programmatic EIS/EIR. For over five years, the Program has relied on continuous comments and involvement from individuals and groups who have a stake in finding long-term solutions for the problems affecting the Bay-Delta system. Participants representing rural, agricultural, municipal, and industrial water users; fishing interests; tribal governments; environmental organizations; businesses; and the general public have helped to define problems and evaluate alternatives to solve the challenges confronting the Bay-Delta system. To date, thousands of Californians have contributed to the Program by participating in public meetings and workshops—volunteering time, sharing expertise, and expressing ideas and opinions. Extensive opportunity for stakeholder participation, including participation by tribal governments, local government and affected individuals will continue to be provided as the Program moves forward.

CALFED's strategic approach for implementation includes working with stakeholders, agencies and local groups to further develop and implement the proposed actions. CALFED's strategic approach for implementation also includes staged implementation and staged decision making. The selection of a Preferred Program Alternative provides the broad resource framework and strategy for implementing a comprehensive Bay-Delta Program. The programmatic decision sets in motion the implementation of some actions, as well as additional planning and investigation to refine other actions. Throughout the implementation period, monitoring will provide information about conditions in the Bay-Delta and results of CALFED actions.

Many comments addressed the program plans released with the Final Programmatic EIS/EIR and not the environmental impact analysis contained within the Final Programmatic EIS/EIR. These comments were helpful in highlighting to the decision makers concerns commenters have about the program plans, but did not directly address the environmental impacts of the Program.

A comment regarding the Monterey Agreement questioned whether a response was misnumbered. The correct responses are IA-5.1-70, IA-5.1-128 and IA-2.2-5 rather than IA-5.1-108.



Lastly, several commenters indicated that the Framework contained activities not included in the Final Programmatic EIS/EIR and that the Framework should be integrated with the Final Programmatic EIS/EIR and the Record of Decision. The Framework described a strategy for implementing the Preferred Program Alternative and most actions described in the Framework are a part of the Preferred Program Alternative described in the Final Programmatic EIS/EIR. The Framework also identified complementary actions generally not analyzed in the Final Programmatic EIS/EIR intended to be pursued through further environmental review. Most actions. The complementary actions not analyzed in the Final Programmatic EIS/EIR are not subject to a final decision at this time. The Framework does not affect, in any way, the environmental analysis that was completed as part of the NEPA/CEQA process.

2.1.3 Preferred Program Alternative

The Preferred Program Alternative consists of a set of broadly described programmatic actions

which set the long-term, overall direction of the 30-year CALFED Program. The description is programmatic in nature, intended to help agencies and the public make decisions on broad methods to meet program purposes. The Preferred Program Alternative is made up of the Levee System Integrity Program, Water Quality Program, Ecosystem Restoration Program, Water Use Efficiency Program, Water Transfer Program, Watershed Program, Storage and Conveyance.

Actions described are intended to take place in an integrated framework and not independently of one another. While each program element is described individually, it is understood that only

through coordinated, linked, incremental investigation, analysis and implementation can we effectively resolve problems in the Bay-Delta system.

Levee System Integrity Program

The focus of the Levee System Integrity Program is to improve levee stability to benefit all users of Delta water and land. Actions described in this program element protect water supply reliability by maintaining levee and channel integrity. Levee actions will be designed to provide simultaneous improvement in habitat quality (consistent with the Ecosystem Restoration Program goals), which will indirectly improve water supply reliability. Levee actions also protect water quality, particularly during low flow conditions when a catastrophic levee breach would draw salt water into the Delta.

There are five main parts to the Levee System Integrity Program plus Suisun Marsh levee rehabilitation work:

- Delta Levee Base Level Protection Plan - Improve and maintain existing Delta levee system stability to meet the Army Corps of Engineers PL 84-99 levee standard.
- Delta Levee Special Improvement Projects - Enhance flood protection for key islands that provide statewide benefits to the ecosystem, water supply, water quality, economics, infrastructure, etc.
- Delta Levee Subsidence Control Plan - Implement current best management practices (BMPs) to correct subsidence adjacent to levees and coordinate research to quantify the effects and extent of inner-island subsidence.
- Delta Levee Emergency Management and Response Plan - The emergency management and response plan will build on existing State, Federal, and local agency emergency management programs.
- Delta Levee Risk Assessment - Perform a risk assessment to quantify the major risks to Delta resources from floods, seepage, subsidence and earthquakes, evaluate the consequences, and develop recommendations to manage the risk.
- Suisun Marsh Levees - Evaluate, and where appropriate, rehabilitate Suisun Marsh levees.

Water Quality Program

The CALFED Program is committed to achieving continuous improvement in the quality of the waters of the Bay-Delta system with the goal of minimizing ecological, drinking water and other water quality problems. Improvements in water quality will result in improved ecosystem health, with indirect improvements in water supply reliability. Improvements in water quality also increase the utility of water, making it suitable for more uses and reuses.

The Water Quality Program includes the following actions:

- Drinking water parameters - Reduce the loads and/or impacts of bromide, total organic carbon (TOC), pathogens, nutrients, salinity, and turbidity through a combination of measures that include source reduction, alternative sources of water, treatment, storage and if necessary, conveyance improvements such as a screened diversion structure (up to 4000

cfs) on the Sacramento River between Hood and Georgiana Slough. The Conveyance section of this document includes a discussion of this potential improvement.

- Pesticides - Reduce the impacts of pesticides through (1) development and implementation of BMPs, for both urban and agricultural uses; and (2) support of pesticide studies for regulatory agencies, while providing education and assistance in implementation of control strategies for the regulated pesticide users.
- Organochlorine pesticides - Reduce the load of organochlorine pesticides in the system by reducing runoff and erosion from agricultural lands through BMPs.
- Trace metals - Reduce the impacts of trace metals, such as copper, cadmium, and zinc, in upper watershed areas near abandoned mine sites. Reduce the impacts of copper through urban storm water programs and agricultural BMPs.
- Mercury - Reduce mercury levels in rivers and the estuary by source control at inactive and abandoned mine sites.
- Selenium - Reduce selenium impacts through reduction of loads at their sources and through appropriate land fallowing and land retirement programs.
- Salinity - Reduce salt sources in urban and industrial wastewater to protect drinking and agricultural water supplies, and facilitate development of successful water recycling, source water blending, and groundwater storage programs. Salinity in the Delta will be controlled both by limiting salt loadings from its tributaries, and through managing seawater intrusion by such means as using storage capability to maintain Delta outflow and to adjust timing of outflow, and by export management.
- Turbidity and sedimentation - Reduce turbidity and sedimentation, which adversely affect several areas in the Bay Delta and its tributaries.
- Low dissolved oxygen - Reduce the impairment of rivers and the estuary from substances that exert excessive demand on dissolved oxygen.
- Toxicity of unknown origin - Through research and monitoring, identify parameters of concern in the water and sediment and implement actions to reduce their impacts to aquatic resources.

Ecosystem Restoration Program

The goal of the Ecosystem Restoration Program is to improve and increase aquatic and terrestrial habitats and improve ecological functions in the Bay-Delta system to support sustainable populations of diverse and valuable plant and animal species. In addition, the Ecosystem Restoration Program, along with the water management strategy, is designed to achieve or contribute to the recovery of listed species found in the Bay-Delta and thus achieve goals of the Multi-Species Conservation Strategy (MSCS). Improvements in ecosystem health will reduce the conflict between environmental water use and other beneficial uses, and allow more flexibility in water management decisions.

The Ecosystem Restoration Program identifies programmatic actions designed to restore, rehabilitate, or maintain important ecological processes, habitats, and species within 14 ecological management zones. Implementation of these programmatic actions will be guided by

six goals presented in the Strategic Plan for Ecosystem Restoration. Nearly 100 restoration objectives have been developed which are directly linked to one of the six goals. Each objective further defines the restoration approach for each ecological process, habitat, species or ecosystem stressor. One to several restoration targets have been developed for each objective to set more specific or quantified restoration levels.

Long-term implementation of the Ecosystem Restoration Program will be guided by the adaptive management approach described in the Strategic Plan for Ecosystem Restoration. This approach to restoration will require review by an ecosystem restoration science review panel and will rely on information developed in the Science Program.

Representative Ecosystem Restoration Program actions include:

- Protecting, restoring, and managing diverse habitat types representative of the Bay-Delta and its watershed.
- Acquiring water from sources throughout the Bay-Delta's watershed to provide flows and habitat conditions for fishery protection and recovery.
- Restoring critical in-stream and channel-forming flows in Bay-Delta tributaries.
- Improving Delta outflow during key periods.
- Reconnecting Bay-Delta tributaries with their floodplains through the construction of setback levees, the acquisition of easements, and the construction and management of flood bypasses for both habitat restoration and flood protection.
- Developing assessment, prevention and control programs for invasive species.
- Restoring aspects of the sediment regime by relocating in-stream and floodplain gravel mining, and by artificially introducing gravels to compensate for sediment trapped by dams.
- Modifying or eliminating fish passage barriers, including the removal of some dams, construction of fish ladders, and construction of fish screens that use the best available technology.
- Targeting research to provide information that is needed to define problems sufficiently, and to design and prioritize restoration actions.

Water Use Efficiency Program

The Water Use Efficiency Program includes actions to assure efficient use of existing and any new water supplies developed by the Program. Efficiency actions can alter the pattern of water diversions and reduce the magnitude of diversions, providing ecosystem benefits. Efficiency actions can also result in reduced discharge of effluent or drainage, improving water quality.

The Water Use Efficiency Program will build on the work of the existing Agricultural Water Management Council and California Urban Water Conservation Council process, supporting and supplementing those processes through planning and technical assistance and through targeted financial incentives (both loans and grants). The Water Use Efficiency Program has identified

potential recovery of currently irrecoverable water losses of over 1.4 million acre-feet of water annually by 2020 as a result of CALFED actions. Early in Stage 1, CALFED will identify measurable goals and objectives for its urban and agricultural water conservation program, water reclamation programs and managed wetlands programs.

Water conservation-related actions include:

- Implement agricultural and urban conservation incentive programs to provide grant funding for water management projects that will provide multiple benefits which are cost-effective at the state-wide level, including improved water quality and reduced ecosystem impacts.
- Identify, in region-specific strategic plans for agricultural areas, quantifiable objectives to assure improvements in water management.
- Expand State and Federal programs to provide increased levels of planning and technical assistance to local water suppliers.
- Work with the Agricultural Water Management Council (AWMC) to identify appropriate agricultural water conservation measures, set appropriate levels of effort, and certify or endorse water suppliers that are implementing locally cost-effective feasible measures.
- Work with the California Urban Water Conservation Council (CUWCC) to establish an urban water conservation BMP certification process and set appropriate levels of effort in order to ensure that water suppliers are implementing cost-effective feasible measures.
- Help urban water suppliers comply with the Urban Water Management Planning Act.
- Identify and implement practices to improve water management for wildlife areas
- Gather better information on water use, identify opportunities to improve water use efficiency, and measure the effectiveness of conservation practices.
- Conduct directed studies and research to improve understanding of conservation actions.

Water recycling actions include:

- Help local and regional agencies comply with the water recycling provisions in the Urban Water Management Planning Act.
- Expand State and Federal recycling programs to provide increased levels of planning, technical, and financing assistance (both loans and grants) and to develop new ways of providing assistance in the most effective manner.
- Provide regional planning assistance that can increase opportunities for the use of recycled water.

Water Transfer Program

The Water Transfer Program proposes a framework of actions, policies, and processes that, collectively, will facilitate water transfers and the further development of a state-wide water transfer market. The framework also includes mechanisms to help provide protection from third party impacts. A transfers market can improve water availability for all types of uses, including the environment. Transfers can also help to match water demand with water sources of the appropriate quality, thus increasing the utility of water supplies.

The Water Transfer Program will include the following actions and recommendations:

- Establish a California Water Transfer Information Clearinghouse to provide a public informational role. The clearinghouse would 1) ensure that information regarding proposed transfers is publicly disclosed and, 2) perform on-going research and data collection functions to improve the understanding of water transfers and their potential beneficial and adverse effects.
- Require water transfer proposals submitted to the DWR, Reclamation, or the State Water Resources Control Board to include analysis of potential groundwater, socio-economic, or cumulative impacts as warranted by individual transfers.
- Streamline the water transfer approval process currently used by DWR, Reclamation, or the State Water Resources Control Board. This would include clarifying and disclosing current approval procedures and underlying policies as well as improving the communication between transfer proponents, reviewing agencies, and other potentially affected parties.
- Refine quantification guidelines used by water transfer approving agencies when they are reviewing a proposed water transfer. This will include resolving issues between stakeholders and approving agencies regarding the application of current agency-based quantification criteria.
- Improve the accessibility of State and Federal conveyance and storage facilities for the transport of approved water transfers.
- Clearly define carriage water requirements and resolve conflicts over reservoir refill criteria such that transfer proponents have a clear understanding of the implications of these requirements.
- Identify appropriate assistance for groundwater protection programs through interaction with CALFED Agencies, stakeholders, the Legislature and local agencies. This is intended to assist local agencies in the development and implementation of groundwater management programs that will protect groundwater basins in water transfer source areas.
- Establish new accounting, tracking, and monitoring methods to aid instream flow transfers under California Water Code Section 1707.

Watershed Program

The goal of the CALFED Watershed Program is to promote locally led watershed management activities and protections that contribute to the achievement of CALFED goals for ecosystem restoration, water quality improvement, and water supply reliability. The Program will accomplish these tasks by providing financial and technical assistance to local community watershed programs.

The Watershed Program includes the following elements:

- Build local community capacity to assess and manage watersheds affecting the Bay-Delta system.
- Develop local watershed assessment and management plans.
- Fund development and implementation of specific watershed conservation, maintenance, and restoration actions identified in these plans.
- Facilitate and improve coordination and assistance among government agencies and local watershed organizations.
- Develop watershed program performance measures and monitoring protocols consistent with the CALFED Science Program.
- Support resource conservation education at the local watershed level, and provide organizational and administrative support to watershed programs.
- Identify the watershed functions and processes that are relevant to CALFED goals and objectives, and provide examples of watershed activities that could improve these functions and processes.

Storage

Groundwater and surface water storage can be used to improve water supply reliability, provide water for the environment at times when it is needed most, provide flows timed to maintain water quality, and protect levees through coordinated operation with existing flood control reservoirs.

Decisions to construct groundwater or surface water storage will be predicated on compliance with all environmental review and permitting requirements, and maintaining balanced implementation of all Program elements. Subject to these conditions, new groundwater and surface water storage will be developed and constructed, together with aggressive implementation of water conservation, recycling, an improved water transfer market, and habitat restoration, as appropriate to meet CALFED Program goals. During Stage 1, through the water management strategy (including the Integrated Storage Investigation), CALFED will continue to evaluate surface water and groundwater storage, identify acceptable project-specific locations, and initiate permitting, NEPA and CEQA documentation, and construction if all conditions are satisfied.

The total volume of new or expanded surface water and groundwater storage evaluated in the Final Programmatic EIS/EIR ranges up to 6 million acre feet, and surface storage facility locations being considered are located in the Sacramento and San Joaquin Valley and in the Delta. Those surface storage sites that will be pursued in Stage 1 are discussed in Section 2.2.5. New groundwater programs could be implemented statewide.

Conveyance

The Preferred Program Alternative employs a through-Delta approach to conveyance. Modifications in the Delta conveyance will result in improved water supply reliability, protection and improvement of Delta water quality, improvements in ecosystem health, and reduced risk of supply disruption due to catastrophic breaching of Delta levees. The Preferred Program Alternative through-Delta conveyance facility actions include:

- Construction of a new screened intake at Clifton Court Forebay with protective screening criteria.
- Construction of either a new screened diversion at Tracy with protective screening criteria; and/or an expansion of the new diversion at Clifton Court Forebay to meet the Tracy Pumping Plant export capacity.
- Implementation of the Joint Point of Diversion (see EWA Operating Principles Agreement in Attachment 2) for the SWP and CVP, and construction of interties.
- Construction of an operable barrier at the head of Old River to improve conditions for salmon migrating up and down the San Joaquin River.
- Construction of operable barriers taking into account fisheries, water quality and water stage needs in the south Delta.
- Operational changes to the SWP operating rules to allow export pumping up to the current physical capacity of the SWP export facilities.

Under the Preferred Program Alternative, north Delta improvements include:

- Studying and evaluating a screened diversion facility on the Sacramento River with a range of diversion capacities up to 4,000 cfs as a measure to improve drinking water quality in the event that the Water Quality Program measures do not result in continuous improvements toward CALFED drinking water goals. Potential diversion sites between and including Hood and Georgiana Slough will be considered as part of this evaluation.

  The diversion facility on the Sacramento River likely would include a fish screen, pumps, and a channel between the Sacramento and Mokelumne Rivers. The diversion facility on the Sacramento River is an action to be considered only after three separate assessments are satisfactorily completed: first, a thorough assessment of Delta Cross Channel (DCC) operation strategies and confirmation of continued concern over water quality impacts from DCC operations; second, a thorough evaluation of the technical viability of a diversion facility; and third, satisfactory resolution of the fisheries concerns about a diversion facility. The assessments of the Delta Cross Channel and the diversion facility on the Sacramento River will be completed simultaneously. The results of all three of these evaluations will be shared with the Delta Drinking Water Council or its successor and the expert panel evaluating fish impacts of Delta conveyance. If these evaluations demonstrate that a diversion facility on the Sacramento River is necessary to address drinking water quality concerns and can be constructed without adversely affecting fish populations, initiate permit and environmental review to enable a decision on siting and construction of

a facility as a part of the Preferred Program Alternative.

- Pursue construction of new setback levees, dredge and/or improve existing levees along the channels of the lower Mokelumne River system from Interstate 5 downstream to the San Joaquin River.

The Preferred Program Alternative includes a process for determining the conditions under which any future additional conveyance facilities or water management actions would be taken. The process would include:

- An evaluation of how water suppliers can best provide a level of public health protection equivalent to Delta source water quality of 50 parts per billion (ppb) bromide and 3 parts per million (ppm) total organic carbon.

- An evaluation based on two independent expert panels' reports -- one on the Program's progress toward these measurable water quality goals and the second on CALFED's progress toward ecosystem restoration objectives, with particular emphasis on fisheries recovery.

2.1.4 Discussion of Alternatives and Comparison to Preferred Program Alternative

No Action Alternative

The No Action Alternative is a description of the anticipated physical, CVP/SWP operation, and regulatory environment that would be in place in 2020 if the Program is not approved and implemented. Impacts of alternatives considered are compared to the No Action Alternative in order to highlight the changes to the environment that would take place as a result of implementing various alternatives.

Compared to the No Action Alternative and existing conditions, the Preferred Program Alternative provides significant improvements in terms of its ecosystem quality, water quality, water supply reliability, and levee system integrity effects. Under the No Action Alternative, each of these four areas of critical concern would continue to deteriorate. In addition, the quality of both in-Delta and export water likely would decline under the No Action Alternative. This decline in water quality would adversely affect irrigated agriculture, ecosystem health, fisheries, and drinking water quality. With the continued decline of the ecosystem, interruptions of water deliveries also likely would occur because of constraints on export pumping to protect threatened and endangered species. Finally, under the No Action Alternative, the Delta levees would continue to be vulnerable to failure because of limited maintenance in some locations and the lack of a comprehensive plan for effective emergency response. The No Action Alternative fails to meet the Program objectives and would result in significant adverse impacts on the health of fisheries, endangered species, species of special concern and their habitat, water quality, and other Bay-Delta resources.

Alternative 1

Under Alternative 1, Delta channels would be maintained essentially in their existing configuration. Several improvements would be made in the south Delta similar to those in the Preferred Program Alternative. The Preferred Program Alternative includes these south Delta actions but also includes actions in the north Delta such as channel modifications for improved water conveyance and flood control and the possible construction of a diversion facility on the Sacramento River. If the diversion facility is not constructed, the Preferred Program Alternative would be the most similar to Alternative 1.

Alternative 1, lacking north Delta channel improvements, would not provide as much flood control benefit in the Delta. Alternative 1 also does not have the potential for water quality improvement provided by the Preferred Program Alternative. The water quality improvement strategy for the Preferred Program Alternative is to aggressively implement the common programs and south Delta improvements, in Stage 1 of implementation, as proposed for Alternative 1. If these water quality objectives are not achieved, the diversion facility on the Sacramento River could be implemented, pending demonstration of benefits for water quality and resolution of fisheries concerns. This contingent action would improve Delta outflow, and decrease salinity and bromide for in-Delta and export water quality.

Alternative 1 would create slightly fewer construction- and facility-related impacts on visual resources, cultural resources, geology and soils, transportation, and air quality compared to the Preferred Program Alternative. Since Alternative 1 does not include a diversion facility on the Sacramento River, it would avoid the associated impacts on fisheries. However, the diversion facility would only be constructed and operated if adverse impacts on fish populations could be avoided. Consequently, the Preferred Program Alternative will not have greater adverse impacts on fish populations than Alternative 1.

Alternative 1 provides less operational flexibility than the Preferred Program Alternative and accordingly could result in fewer benefits to water supply reliability, and water quality. While Alternative 1 would substantially meet the Program's goals and primary objectives, Alternative 1 provides less operational flexibility and is less effective in meeting the Program objectives for water quality, water supply reliability and flood control as compared to the Preferred Program Alternative.

Alternative 2

Alternative 2 would employ a modified through-Delta conveyance approach. Significant improvements to north Delta channels, including construction of setback levees and channel dredging, and construction of a 10,000 cfs diversion from the Sacramento River to the Mokelumne River and associated fish protection facilities, would accompany the south Delta improvements contemplated under Alternative 1 and the Preferred Program Alternative.

The diversion would send greater volume and better quality water from the Sacramento River into the north Delta and east Delta. The diverted water would improve net-Delta outflow which helps to isolate the south Delta pumps from salinity intrusion and reduces the entrainment of San Joaquin River fish. The quality of in-Delta and exported water quality and would improve as compared to the Preferred Program Alternative.

However, Alternative 2 could result in significant adverse impacts on fisheries from the 10,000 cfs diversion facility. Fish mortality would increase as a result of reduced flow on the Sacramento River downstream of the diversion and greater proportion of fish entering Georgianna Slough and the Mokelumne River. Fish mortality would also increase from entrainment at the diversion. There is substantial uncertainty whether a facility as large as 10,000 cfs could be operated and screened sufficiently to avoid or minimize significant adverse effects on fish populations.

While the Preferred Program Alternative incorporates many of the benefits of Alternative 2 derived from north Delta channel modifications, there is uncertainty and concern that objectives for export and in-Delta water quality can be achieved with the common program elements and these actions. If water quality objectives not be met, the Preferred Program Alternative includes a diversion facility on the Sacramento River as a contingent measure to improve export water quality. The facility would have a capacity no greater than 4000 cfs which would substantially reduce impacts on fisheries, and would provide similar, but less pronounced, water quality improvement as Alternative 2. The diversion facility would only be constructed if it is determined that significant adverse impacts on fish populations can be avoided. Alternative 2 does not include this option. While Alternative 2 could meet the Program's goals and primary objectives to some extent, the water quality benefits of Alternative 2 are outweighed by greater technological uncertainty and adverse impacts on fisheries as compared to the Preferred Program Alternative. Accordingly, Alternative 2 is less effective in meeting the Program objectives.

Alternative 3

Alternative 3 would employ a dual-conveyance approach employing a combination of through-Delta improvements similar to the Preferred Program Alternative and an isolated diversion facility on the Sacramento River to take water by canal to the export facilities in the south Delta.

Initially, the dual-Delta conveyance approach with an isolated facility appeared to provide greater technical performance than the other alternatives. Some of the preliminary scientific and engineering evidence suggests that a dual-Delta conveyance configuration may improve export water quality and achieve fish recovery most effectively. Relative to the Preferred Program Alternative, Alternative 3 would improve export water quality and improve Delta flow patterns for fish migration, including reduced incidence of reverse flow and entrainment in the south Delta pumps.

However, other evidence indicates that such a conveyance configuration can cause significant in-Delta water quality problems. The diversion would substantially reduce the flow of the

Sacramento River below the diversion and could aversely affect fish migration and survival. The isolate facility would have a capacity between 5,000 cfs and 10,000 cfs. Higher capacity diversion would pose problems similar to Alternative 2. Additionally, construction-related impacts, land conversion and impacts from operation of the isolated facility, such as seepage, would be substantially greater under the Preferred Program Alternative.

In addition, during scoping and public meetings, many stakeholders and agencies voiced numerous concerns, including the difficulty of in ensuring the appropriate operation of such a facility, fear that an isolated facility will decrease the incentive to manage the Delta as a "common pool" in which export water supply is coupled with the preservation of the Delta, that decreased dependence on a on a through-Delta approach could undermine the commitment for balanced solutions involving maintaining Delta levees, improving in-Delta quality and pursuing ecosystem restoration.

For these reasons, Alternative 3 presents the most serious challenges in terms of cost, scientific uncertainty, assurances and implementation. While Alternative 3 may technically perform better for certain resource areas than the Preferred Program Alternative, it is not clear that the additional cost and risk associated with the isolated facility would be worth the benefits. Years of scientific evaluation would be necessary to determine whether an isolated facility would be needed to meet water quality, water supply reliability and fisheries objectives. At the earliest, evaluation, design and permitting the facility would take ten years. Lastly, the isolated facility is so contentious that stakeholder support for the Program would be significantly eroded. Such lack of support could threaten the viability of the entire Program.

The Preferred Program Alternative has a high likelihood of success in a shorter time period. The Preferred Program Alternative also has lower risk, is less controversial, and would require less modification of the environment than Alternative 3. Alternative 3 is rejected as infeasible due to social and technical considerations, based in large part due to the contentiousness and time associated with an isolated conveyance facility and the uncertainty that it will achieve the Program objectives any better than the Preferred Program Alternative.

2.1.5 Environmentally Preferable/Superior Alternative

As described above, the Preferred Program Alternative adopts a set of programmatic actions designed to achieve the objectives for each of the resource areas while evaluating the effectiveness of those actions, and assessing whether modifications may be needed to meet Program goals and objectives. Accordingly, the Preferred Program Alternative is the "Environmentally Preferable Alternative" under NEPA and the "Environmentally Superior Alternative" under CEQA.

The problems and potential solutions facing the Bay-Delta involve a complex set of interrelated biological, chemical, and physical systems. This complexity, coupled with the broad scope and number of actions needed to implement the Program, the 30-year or more implementation period,

the need to test hypotheses, and resource limitations make it necessary to implement the Program in stages. Consequently, the Preferred Program Alternative provides for implementation of the Program in a staged manner and establishes mechanisms to obtain the necessary additional information to guide the next stage of decision making.

The Preferred Program Alternative consists of a through-Delta conveyance approach, coupled with ecosystem restoration, water quality improvements, levee system improvements, increased water use efficiency, improved water transfer opportunities, watershed restoration, and additional surface waters and groundwater storage. The Preferred Program Alternative meets the Program's multiple purposes, reduces adverse environmental effects, and provides a system of research and monitoring to determine whether modifications or additional actions are needed. It provides multiple benefits, including but not limited to:

- Modifying the timing and magnitude of flow to restore ecological processes and to improve conditions for fish, wildlife, and plants in the Bay-Delta system.
- Improving and increasing aquatic and terrestrial habitats.
- Modifying and eliminating fish passage barriers.
- Constructing fish screens that use the best available technology.
- Reducing the loads and impacts of bromide, total organic carbon, pathogens, nutrients, salinity, and turbidity.
- Reducing the impacts of pesticides.
- Reducing the impacts of trace metals, mercury, and selenium.
- Improving and maintaining the stability of the Delta levees and, after evaluation, appropriately improving and maintaining the Suisun Marsh levee system.
- Enhancing flood protection for key Delta islands.
- Expanding and implementing agricultural and urban conservation incentive programs.
- Implementing better water management for managed wetlands.
- Facilitating water transfers while protecting third parties from potentially significant adverse impacts.
- Supporting local watershed restoration, maintenance, and conservation activities.
- Developing appropriate groundwater and surface storage in conjunction with specified water conservation, recycling, and water transfer programs to provide water for the environment at times when it is needed most, and to improve water supply reliability.
- Modifying existing Delta conveyance systems for improved water supply reliability and water quality, improved ecosystem health, and reduced risk of supply disruption due to catastrophic breaching of Delta levees.

Although the CALFED Agencies did not rule out the possibility of constructing an isolated conveyance facility in the future, they were mindful that, even if approved immediately following the ROD, such a facility could not be studied, approved, funded, and constructed within Stage 1 of implementation.

In light of the technical and feasibility issues discussed above, the CALFED Agencies propose to begin with through-Delta modifications. As part of the Preferred Program Alternative, the Program also would:

- Continue to investigate storage opportunities in the context of the broader water management strategy.
- Evaluate and implement storage projects, predicated on complying with all environmental review and permitting requirements. These efforts will be coordinated under CALFED's Integrated Storage Investigation.
- Implement the Stage 1 of the Ecosystem Restoration, Water Quality, Water Use Efficiency, Water Transfers, Watershed, and Levee System Integrity Program Plans.
- Monitor the results of these actions to determine whether an isolated conveyance facility as part of a dual-Delta conveyance configuration is necessary to meet the Program objectives.

If the Program purposes cannot be fully achieved with the actions proposed in the Preferred Program Alternative, additional actions including an isolated conveyance facility will need to be considered in the future. Until additional information is available to determine whether water quality objectives and fish recovery goals can be met and which, if any, additional actions will be necessary to achieve the Program goals and objectives, the Preferred Program Alternative is the best alternative to achieve overall project purposes and provide significant beneficial improvements over the conditions anticipated under the No Action Alternative, while establishing a process for obtaining this additional information. Moreover, the way the alternatives are structured, going forward with the Preferred Program Alternative does not preclude the Program's ability to undertake additional conveyance actions in the future, subject to appropriate environmental review.

2.1.6 Mitigation

Mitigation Measures Adopted

The Final Programmatic EIS/EIR sets out many potential mitigation measures (see Appendix A to this ROD) to be used during project-specific planning where appropriate. The CALFED Agencies will consider and adopt these measures when conducting second-tier environmental review. In addition to the mitigation measures identified at the programmatic level, the CALFED Agencies will also consider and adopt feasible mitigation measures intended to address project-specific impacts.

In considering effects from the CALFED Program together with effects of other similar projects, the cumulative impact analysis did not identify any additional effects that individually would be minor, but collectively significant. As a result, the analysis of the CALFED Program's contribution to cumulative effects is very similar to the analysis of its long-term effects. The

mitigation strategies identified for the CALFED Program effects are also applicable to mitigate the CALFED Program's cumulative effects.

Mitigation Measures Not Adopted

Generally, mitigation measures were not adopted in this ROD where they were inappropriate or not practicable. Specifically, a measure was not adopted where a mitigation measure is similar to a measure incorporated, a measure is less effective than a measure incorporated, a measure is ineffective for mitigating an adverse effect, a measure is too project-specific for a programmatic document, a measure addresses an impact that is not caused by the CALFED Program, a measure does not address an environmental effect or a measure is not practicable.

Appendix B to this ROD, incorporated herein, contains a list of mitigation measures not adopted and includes reasons why specific measures were not adopted.

Mitigation Monitoring Plan

Projects and activities that implement the CALFED Preferred Program Alternative will be monitored to ensure that mitigation strategies developed in the Final Programmatic EIS/EIR are considered, adopted and implemented. CALFED Agencies will use this mitigation monitoring plan for projects that are within the scope of the Final Programmatic EIS/EIR and carried out or funded by CALFED Agencies as part of the CALFED Program. If and when a new governing agency with authority to carry out CALFED projects is created, this plan would apply to that new agency as well.

Projects and activities implementing the Preferred Program Alternative will undergo future environmental analysis tiering from the Final Programmatic EIS/EIR. In order to qualify for CALFED funding, any implementing project must demonstrate its compliance with this mitigation monitoring plan. As part of these second-tier environmental reviews, the lead agency for each of these projects will use the mitigation strategies (see Appendix A to this ROD) as a starting point to determine appropriate mitigation measures. Because all the potential actions and impacts for tiered projects cannot be anticipated at a programmatic level, each project needs to select those strategies and actions applicable to the specific location and type of action and to consider additional project-specific mitigation measures.

The mitigation monitoring plan includes review, guidance, and reporting components. The CALFED Agencies will prepare a checklist of the mitigation strategies (Appendix A to this ROD) to provide guidance to lead agencies preparing environmental documents that tier from the Final Programmatic EIS/EIR. The lead agencies for second tier documents will note which applicable programmatic mitigation strategies are being adopted and explain why others are not. They will provide a schedule for implementing the adopted mitigation measures, and for reviewing the implementation of those measures. The lead agencies will provide a written report periodically,

but at least once a year to the CALFED Agencies for programmatic review by the lead scientist as to the overall progress in implementing the mitigation measures and the efficacy thereof. A summary of this information will be included in the annual report described in Section 1.1.

2.2 Plan for Action

2.2.1 Governance

Through five years of planning, the CALFED *process* for implementing the Program has assumed an importance virtually equal to the CALFED *actions*. Stakeholders often raise concerns about their role in implementation or about how a particular action will be implemented. This section briefly describes the CALFED Agencies' plan for addressing interim as well as long-term governance issues.

Interim Process

The CALFED Agencies have executed a memorandum of understanding (Attachment 3 to this ROD) that establishes the process for governing implementation of the CALFED Program until the Legislature and Congress establish a new governing structure. The Implementation MOU does not create a new entity or modify existing agency authority. Instead, it identifies the agencies that will lead implementation of each Program element and establishes the CALFED Policy Group as the oversight and coordination body for CALFED implementation.

Long-Term Proposal

After nearly a decade of slow but tangible progress toward shared decision-making and funding, the CALFED Agencies will work with the State Legislature and the Congress to develop legislation for a permanent joint Federal-State commission with shared power to appoint commission members. This approach will require resolution of Federal Constitutional concerns. The new commission would provide direction and oversight in implementing the long-term plan described in this document and the Final Programmatic EIS/EIR. A joint commission made up of high-level appointees would maintain visibility inside and outside the government, assure agency coordination, help secure funding, and provide policy leadership and accountability.

Major responsibilities of the Commission would include: reviewing and approving program priorities and budget proposals; assessing and reporting on progress toward program goals; coordinating within CALFED and with related programs to maximize resources and reduce conflicts; resolving disputes among CALFED Agencies; and maintaining contact with and receiving communications from the public and the media, as well as Congress and the California Legislature. The overarching mandate of the Commission would be to assure effective, balanced

and coordinated implementation in all program areas.

The Commission should be composed of equal numbers of high level officials of the Federal and State agencies responsible for implementing CALFED programs and a similar number of stakeholder and tribal representatives. This structure is generally consistent with the recommendation of the Bay-Delta Advisory Council. For example, the Commission could have 12 members, as follows: four Federal members - from among the U.S. Environmental Protection Agency (EPA), Natural Resources Conservation Service (NRCS), U.S. Army Corps of Engineers (USACE), National Marine Fisheries Service (NMFS)/National Oceanic and Atmospheric Administration (NOAA), Reclamation, U.S. Fish and Wildlife Service (USFWS); four State members - California Department of Fish and Game (DFG), California Department of Water Resources (DWR), California Environmental Protection Agency (CalEPA), Resources Agency; and four other members, representing rural/agricultural water user communities, urban water user communities, environmental advocates and tribes. This structure would ensure a close relationship between the Commission, CALFED Agencies, and the stakeholder community.

As described in Attachment 3, the Commission would be assisted by an advisory committee whose members would include representatives of Indian tribes, local governments and stakeholder groups, including environmental justice representatives. The advisory committee members would be selected based on their experience and expertise in relevant fields, such as ecosystem restoration, agriculture, hydrology, urban water management, fishery biology, water quality, flood management, water conservation and recycling, and economics. Appointments would be made to assure that the advisory committee as a whole is both balanced and diverse. Representatives of CALFED Agencies would attend advisory committee meetings and provide information and updates to the committee.

Implementation Commitments

Local Leadership. The CALFED Agencies will rely on leadership in local communities across the State to provide advice and support for implementing CALFED projects affecting their communities.

Stakeholder Consultation. The CALFED Agencies will continue to solicit and incorporate diverse stakeholder perspectives into its decisions and actions as they implement the CALFED Program. The Secretary of the Interior will charter a new Federal advisory committee and will consult with the Governor regarding membership of the new committee.

Environmental Justice. Consistent with Federal and State authorities including Federal Executive Order 12898, Title VI of the Civil Rights Act of 1964 and recent State legislation, the CALFED Agencies are committed to addressing environmental justice challenges related to the management of water in the Bay-Delta watershed. For example, it is important to examine the potential effects of water management reforms on rural

communities and the public health and financial impacts of ERP and Water Quality Program actions on the large numbers of minorities and disadvantaged people living in urban as well as rural areas. The CALFED Program and its participating agencies are committed to seeking fair treatment of people of all races, cultures, and incomes, such that no segment of the population bears a disproportionately high or adverse health, environmental, social or economic impact resulting from CALFED's programs, policies, or actions. The CALFED Agencies will be responsible for ensuring this policy is carried out across all program areas through the development of environmental justice goals and objectives.

By the end of December 2000, the CALFED Agencies will collaborate with environmental justice and community stakeholders to develop a comprehensive environmental justice workplan across all program areas. This workplan will ensure that the CALFED Agencies develop the capacity and process to understand, monitor, and address environmental justice issues as the program moves into implementation, including identifying and developing specific methods to address and mitigate environmental justice impacts. This workplan should, at a minimum, include commitments such as the development of environmental justice goals and objectives for each program area, investments in staff and resources across program areas and agencies, development and implementation of an environmental justice education program for agency and program staff, collection and analysis of additional demographic information to assist in the identification of impacts, and actions to ensure effective participation on technical and advisory workgroups by those populations adversely impacted.

Tribal Consultation. Consistent with the President's April 29, 1994, Memorandum, the CALFED Agencies will assess the impact of CALFED project-specific plans, projects and activities on tribal trust resources and tribal government rights and concerns. The CALFED Agencies will actively engage federally recognized tribal governments in the planning and development of specific projects in their areas and will consult with such tribes on a government-to-government basis, to the greatest extent practicable and to the extent permitted by law, prior to taking actions that affect such tribal governments. At the request of any tribal government, the CALFED Agencies will enter into a Memorandum of Understanding with that tribal government or multiple tribal governments that will specify the process for how the federal, state and tribal governments will work together, on a government-to-government basis, in developing CALFED projects.

Land Acquisition. Successful implementation of the CALFED Program will affect some agricultural lands. As an important feature of the State's environment and economy, agricultural lands will be preserved during implementation of the Program in a manner consistent with meeting program goals, minimizing impacts to agriculture. Some of the land needed for program implementation is already owned by the Federal or State government and that land will be used to achieve program goals. Partnerships with landowners, including easements with willing landowners, will be pursued to obtain mutual benefits if public land is not available for the intended purpose. Acquisition of fee

title to land will be from willing sellers only, and will be used when neither available public land nor partnerships are appropriate or cost-effective for the specific need. Such acquisitions will consider the potential for third-party and redirected impacts. In addition, to the maximum extent possible, the CALFED Agencies will seek to implement the Program through technical and financial assistance to locally based, collaborative programs such as the Sacramento River Conservation Area/SB 1086 program.

CALFED Agency Coordination. The CALFED Bay-Delta Program has established an important precedent in coordinated and cooperative State and Federal agency relationships. These improved institutional relationships are expected to extend to other programs in which these agencies continue to have roles. Other programs include those developed to address statewide water supplies and demands.

Integration of Non-Signatory Agencies. The CALFED Agencies intend to work with Federal and State agencies that implement other programs that relate to CALFED's mission. While these agencies will not serve as part of the governing structure or incorporate their programs into CALFED, the CALFED Agencies will coordinate their implementation of the CALFED programs with these non-CALFED programs. The CALFED Executive Officer and staff will coordinate with the other agencies' programs and identify conflicts as soon as possible. In some cases, CALFED Agencies or a successor agency may establish contractual relationships with non-CALFED Agencies to implement certain CALFED programs.

Environmental Documentation. The CALFED Agencies will fulfill their respective legal responsibilities for environmental analysis, documentation and permitting pursuant to NEPA, CEQA and all other environmental laws. As indicated below, the CALFED Agencies and/or the new CALFED Commission will complete the necessary programmatic and project-specific analysis of programs and projects.

Permit Clearinghouse. The CALFED Agencies will establish a clearinghouse for obtaining the necessary permits and approvals for CALFED Program implementation. This permit clearinghouse will be established by December 2000.

Adaptive Management/Science. The CALFED Agencies will use science-based adaptive management in the implementation of the CALFED Program.

Beneficiaries Pay. A fundamental philosophy of the CALFED Program is that costs should, to the extent possible, be paid by the beneficiaries of the program actions.

Compliance With Water Rights Laws. The CALFED Agencies will comply with California's water rights laws, including area-of-origin statutes, applicable to their respective actions. Nothing in this ROD is intended to affect existing water rights or water right holders. In the few areas where CALFED Agencies may propose changes to California law (e.g., transfers, appropriate water use measurement), the CALFED

Agencies will work with all interested parties potentially affected by such changes in developing legislative proposals.

Project Operations. In order to promote more efficient water project operations, the operators of the State Water Project (SWP) and Central Valley Project (CVP) will continue to meet regularly with the fishery agencies through the CALFED Operations Group (Ops Group) which has been re-established in the Implementation MOU.

Coordinated Operation Agreement. DWR and Reclamation intend to modify the 1986 CVP/SWP Coordinated Operation Agreement (COA) in order to reflect the many changes in regulatory standards, operating conditions and the EWA. DWR and Reclamation will commence renegotiation of the COA by the middle of 2001.

2.2.2 Ecosystem Restoration

The CALFED Agencies will implement a comprehensive Ecosystem Restoration Program (ERP) throughout the Bay-Delta's watershed, consistent with the Strategic Plan for Ecosystem Restoration. The goal of the ERP is to improve aquatic and terrestrial habitats and natural processes to support stable, self-sustaining populations of diverse and valuable plant and animal species through an adaptive management process. Implementation of the ERP includes recovery of species listed under the State and Federal Endangered Species Acts.

Actions Included in the Programmatic EIS/EIR

To achieve its objectives, the ERP identifies over 600 programmatic actions in all the regions of the Bay-Delta watershed. CALFED's ERP will undertake the following actions using a science-based adaptive management framework, consistent with the ERP Strategic Plan and on-going scientific review. Additional information on the ERP Science Program can be found in the ERP Strategic Plan. The actions listed here are explained in greater detail in Volumes I and II of the ERP and in the ERP Strategic Plan. ERP actions include, but are not limited to:

- Implement large-scale restoration projects on selected streams and rivers including Clear Creek, Deer Creek, Cosumnes River, San Joaquin River and Tuolumne River, in cooperation with local participants.

- Improve fish passage through modifications or removal of the following locally owned dams: small diversion dams on Butte Creek; eight Pacific Gas & Electric Company diversion dams on Battle Creek; McCormick-Saeltzer Dam on Clear Creek; Woodbridge Dam on Mokelumne River; and Clough Dam on Mill Creek. CALFED Agencies will support studies to determine if introduction of wild chinook salmon and steelhead to the upper Yuba River watershed is biologically, environmentally, and socio-economically feasible over the long term and will recommend other fish passage projects through the

Integrated Storage Investigation (ISI). Local interests will participate in implementing these actions, with funding shared by CALFED Agencies and the local interests, based on individual circumstances.

- Restore habitat in the Delta, San Pablo Bay, Suisun Bay and Suisun Marsh, and Yolo Bypass including tidal wetlands and riparian habitat. In addition, 8,000 to 12,000 acres of wildlife-friendly agricultural lands will be established during Stage 1, in cooperation with local participants.

- Restore habitat and hydraulic needs on Frank's Tract in the Delta to optimize improvements in ecosystem restoration, levee stability, and Delta water quality. CALFED Agencies will decide the scope and feasibility of the project by 2002, and begin implementation by the end of Stage 1.

- Improve salmon spawning and juvenile survival in upstream tributaries as defined by the ERP and Strategic Plan**,** by purchasing up to 100 TAF per year by the end of Stage 1. Some of these ERP flows may contribute to the EWA.

- Complete protection and restoration of the Sacramento River meander corridor as part of the Sacramento River Conservation Area/SB 1086 program, including easement or purchase of an additional 15,000 acres, revegetation, and restoration of stream meander function by the end of Stage 1.

- Implement an invasive species program, including prevention, control and eradication.

- Assess the potential need for additional fish contamination monitoring and consumption advisories in the Bay-Delta watershed. If gaps are found, fund additional monitoring, testing, analysis, outreach, pollution prevention, and implementation of best management practices, as appropriate, by the end of Stage 1.

- Assist existing agency programs to reduce turbidity and sedimentation; reduce the impairment caused by low dissolved oxygen conditions; reduce the impacts of pesticides including organochlorine pesticides; reduce the impacts of trace metals; mercury; and selenium; reduce salt sources to protect water supplies; and increase understanding of toxicity of unknown origin.

- Improve dissolved oxygen conditions in the San Joaquin River near Stockton. The dissolved oxygen in the San Joaquin River, in the vicinity of Stockton, dips below State environmental criteria, causing a migratory block for salmon and threatening other fish. CALFED proposes simultaneous investigation of specific causes as well as investigation of innovative methods to reduce problem pollutants in the river. Proposition 13 includes $40 million to construct facilities as part of this effort. Actions include:

  S Finalize investigation of methods to reduce constituents that cause low dissolved

oxygen by the end of 2001 to be included in the Total Maximum Daily Load recommendation to the Central Valley Regional Water Quality Control Board (CVRWQCB).

- **S** Finalize State Basin Plan Amendment and Total Maximum Daily Load for constituents that cause low dissolved oxygen in the San Joaquin River by the end of June 2002.
- **S** Begin implementation of appropriate source controls and other controls as recommended in the Total Maximum Daily Load by the end of 2002.

Single Blueprint for Restoration and Recovery: MSCS-ERP Milestones

The CALFED Agencies will establish, through the ERP and the MSCS, a single blueprint for restoration and species recovery within the geographic scope of the CALFED ERP. The ERP is the Program's blueprint for restoration of the Bay-Delta. The MSCS is not a separate blueprint or supplemental restoration program and does not supplant the ERP. The measures and goals in the MSCS are derived from, or are consistent with, the ERP's measures and goals.

The ERP will be informed by the Science Program, which will monitor and evaluate the implementation of the ERP actions and conduct pertinent research. The ERP and the Science Program are important for Federal Endangered Species Act (FESA), California Endangered Species Act (CESA) and Natural Community Conservation Plan (NCCP) compliance, and are integral to the MSCS. To ensure that the ERP is implemented in a manner and to an extent sufficient to sustain programmatic FESA, CESA and NCCP compliance for all program elements, USFWS, NMFS, and DFG have developed MSCS-ERP Stage 1 Milestones. USFWS, NMFS, and DFG have concluded, based on the best information currently available, that the MSCS-ERP Milestones, if achieved as specified in the Programmatic Regulatory Determinations, define a manner and level of ERP implementation in Stage 1 sufficient to achieve the MSCS's species goals. USFWS, NMFS, and DFG expect and intend that the MSCS-ERP Milestones will be achieved with annual ERP funding of $150 million, as described below (see Funding).

To ensure that substantial progress in being made to achieve the MSCS-ERP Milestones, the USFWS, NMFS, and DFG will participate in an annual process with the ERP and Science Programs to: 1) develop annual and long-term ERP implementation priorities and strategies; 2) develop annual implementation plans; and 3) assess the implementation and performance of ERP actions, including measuring progress towards achieving the MSCS-ERP Milestones. USFWS, NMFS, and DFG expect that the MSCS-ERP Milestones may be revised to reflect new information derived in the process.

Funding

In Stage 1, CALFED plans to invest over $1 billion in ERP projects, in accordance with the priorities established in the Strategic Plan, in addition to funds necessary for the EWA. To be

successfully implemented, the ERP must have at least $150 million from dedicated funding sources annually through Stage 1. (There may be many ways to achieve this.) An additional $50 million will be required annually for the EWA for the first four years. It is anticipated that additional funding to support the EWA will be needed beyond the first four years. To the extent that the EWA acquires a share of new storage and conveyance projects, the need for EWA funding for annual acquisitions of water will be reduced. The level of assets required to support continuation of the EWA beyond the first four years will be evaluated and will be included in a revised biological opinion.

For the ERP, the CALFED Agencies propose a combination of State funding (including Proposition 204 funds), Federal funding, and user fees. Consistent with this proposal, the State has allocated over $173 million in FY 2000-2001, including $100 million from Proposition 204, $35 million from the general fund, $25 million from Proposition 13, and $13 million from Proposition 12. Additionally, through FY 2000, Federal funds in the amount of $190 million have been provided through Reclamation. During the first years, State and Federal funds would provide the bulk of funding, supplemented by approximately $15 million of Central Valley Project Improvement Act (CVPIA) Restoration Funds, and SWP contributions under the Four Pumps Agreement. Following issuance of this ROD, the CALFED Agencies will work with local interests to develop State legislation to create a broad-based user fee that will generate approximately $35 million annually. The CALFED Agencies also will consider the availability of Federal funds. By the end of Stage 1, CALFED will reevaluate the level of dedicated annual funding from State, Federal, and user sources to achieve the ERP goals.

Complementary Action

The Framework identified the following action which was not analyzed in the Final Programmatic EIS/EIR and will, therefore, require additional environmental review.

- Implement integrated flood management, ecosystem restoration and levee restoration under the Sacramento/San Joaquin River Basins Comprehensive Study being prepared by the USACE and California Reclamation Board. Significant elements of this Comprehensive Study, when implemented, will further the purposes of the ERP. The CALFED Agencies intend that final development and implementation of actions under the Comprehensive Study will be coordinated and consistent with the CALFED Bay-Delta Program.

In addition to the ERP actions funded through CALFED, ongoing State and Federal commitments to fish and wildlife restoration will continue and will supplement the achievement of the CALFED objectives and activities. These programs include CVPIA and Four Pumps Agreement among others.

2.2.3 Watersheds

The goal of the CALFED Watershed Program is to promote locally led watershed management activities and protections that contribute to the achievement of CALFED goals for ecosystem restoration, water quality improvement, and water supply reliability. The CALFED Agencies will encourage and support local efforts to resolve issues throughout watersheds in the solution area (both above and below the primary tributary dams). The CALFED Program will support local implementation with funding, coordination, and technical assistance. CALFED proposes investing $300 million in this watershed program in Stage 1.

Watershed plans and actions will be developed to achieve multiple objectives: improved water supply reliability, flood management, environmental restoration, and water quality. For example, the Watershed program anticipates providing assistance to community based organizations in the American River watershed. Current efforts underway in this watershed are focused on forest and fuels management issues, and reducing the threat of catastrophic wildfire. Addressing these issues on a watershed scale can result in reduced water quality impacts and increased aquatic and terrestrial habitats for important species of concern.

Actions Included in the Programmatic EIS/EIR

The major Stage 1 elements of the Watershed Program include:

- Establishing a grant program in the first year to solicit, evaluate and fund local projects that contribute to achieving CALFED goals. The watershed activities targeted by this program will:

  - Build local capacity to assess and manage watersheds affecting the Bay-Delta system.
  - Develop watershed assessments and management plans.
  - Fund development and implementation of specific watershed conservation, maintenance and restoration actions.

  The CALFED Watershed Program has designed a three-step process for soliciting, evaluating and selecting an initial set of demonstration watershed projects: 1) solicitation of watershed projects that meet Program's selection criteria; 2) further proposal development by CALFED staff, the Watershed Workgroup, and an Interagency Watershed Advisory Team; and 3) evaluation and selection of proposals. CALFED's criteria for selecting projects will be based on the following:

  - A balance of diverse watershed activities that demonstrate the potential to improve the Bay-Delta system.
  - Application to multiple CALFED objectives in an integrated fashion, with emphasis on water supply reliability, water quality, and levee stability.

- S A variety of watershed settings, such as forest lands, agricultural, urban, mixed, etc., are represented.
- S Geographical distribution throughout the CALFED solution area.
- S Project costs and anticipated results.

C Developing watershed program performance measures and monitoring protocols consistent with the CALFED Science Program by the end of 2002.

Local Leadership

Building local consensus about management of individual watersheds is particularly important to the watershed program. CALFED Agencies are therefore committed to fostering the development of local watershed groups that include adjacent landowners, community members (particularly representatives from traditionally under-represented groups), environmental advocacy groups and locally-involved public agencies (Federal, State and local).

2.2.4 Water Supply Reliability

One of the primary goals of CALFED is to improve the reliability of California's water supply within the context of unpredictable hydrology and the competing needs of fish and wildlife and water users. In addition to hydrology, actions taken in Stage 1 assume that water supply reliability is predicated upon the following factors:

C Clear and consistent implementation of all regulatory decisions and project operations.
C Flexibility, water use efficiency and interagency cooperation to avoid water supply/fish/water quality conflicts where possible.
C Investment in infrastructure to improve storage and conveyance capacity.

Actions Included in the Programmatic EIS/EIR

Actions initiated in the first four years of Stage 1 to improve storage and conveyance capacity (see following sections on Storage and Conveyance) will substantially increase water supply reliability in the later years, but these benefits will not be realized until the new facilities come on line. Similarly, it will take years to implement and fully realize the water supply benefits of water use efficiency, recycling and other conservation measures. Therefore the greatest challenge to improving water supply reliability lies in the first four years of Stage 1.

To address these water supply reliability challenges in this period, CALFED Agencies are taking the following actions in this ROD:

C Establishing an EWA with an average of 380 TAF of water set aside annually in the first years to provide additional water for fishery purposes beyond the regulatory baseline. Water assets will be acquired by CALFED Agencies, consistent with the goals of the

CALFED Water Transfer Program.

- Establishing a Regulatory Baseline by delineating existing regulatory requirements and clarifying implementation of specific regulatory actions (see EWA Section).
- Providing a commitment that there will be no reductions, beyond the baseline regulatory levels described below, in CVP or SWP Delta exports to State and Federal project water users resulting from measures to protect fish. This commitment will initially be provided for the first four years of Stage 1, as outlined in the MSCS Conservation Agreement (see Attachment 5 to this ROD).

In addition, CALFED Agencies will take the following actions in Stage 1:

- Seek SWRCB approval of Joint Point of Diversion and share water derived from Joint Point of Diversion between the CVP and the EWA.
- Implement conjunctive management projects, water conservation measures and water transfers, as described in the sections below.
- Allocate Proposition 13 funds dedicated to interim water supply reliability and water quality.

Proposition 13 contains over $630 million for these purposes, including the following:

- **S** $200 million for groundwater storage projects.
- **S** $250 million for Stage 1 water quality actions and water management actions.
- **S** $180 million for water supply and water quality infrastructure projects in areas that draw supplies from the Delta.

In the first four years of Stage 1, it is anticipated that water deliveries will remain at recent levels for most water users who depend upon water from the CVP, including Exchange Contractors, North of Delta CVP agricultural contractors, refuges, and M&I contractors, as well as for SWP contractors and non-project water users. It is also anticipated that implementation of Joint Point of Diversion, operational flexibility, interagency cooperation, EWA implementation, and other cooperative water management actions (some of which may require further specific environmental review) will result in normal years in an increase to CVP south-of-Delta agricultural water service contractors of 15 percent (or greater) of existing contract totals to 65 to 70 percent. This normal year supply improvement may not be achieved in all years due to annual hydrologic variability and its impact on carryover storage conditions. Substantial progress toward implementation of other program elements, such as development of EWA assets, is also necessary. Water supplies in dry years are likely to be less than the anticipated amounts and more in above normal years. As discussed in this ROD, CALFED Agencies are committed to working with local agencies to implement these regional supply actions and to support local water management actions including conservation and other local measures. Part of this effort will include development of a plan for alternative refuge supplies and conveyance.

The Secretary of the Interior is expected to make a decision later this year on Trinity River flows

pursuant to the original Trinity authorization, the Trinity Restoration Act of 1984, and the CVPIA. The substance of that decision is unknown and therefore cannot be addressed at this time. It is separate from and will not be affected by this ROD. Certain CALFED Agencies have considered the potential that the Trinity River decision may affect CVP allocation and have concluded that it will not affect the allocations to CVP south-of-Delta agricultural water service contractors described immediately above.

Complementary Action

The Framework identified the following action which was not analyzed in the Final Programmatic EIS/EIR.

- **Governor's Drought Contingency Plan.** CALFED Agencies recognize that in the next several years critical water shortages may occur that severely impact the health, welfare and economy of California. To avoid such serious impacts, the Governor has convened a panel, chaired by the Director of DWR, for the purpose of developing a contingency plan to reduce the impacts of critical water shortages primarily for agricultural and urban water users. The plan will identify all available resources (e.g., water transfers, water exchanges, groundwater programs, local partnerships), building upon the experience gained with Governor's Drought Water Bank, to minimize such shortages. The plan also will recommend appropriate funding mechanisms. In addition, CALFED Agencies commit to facilitate transfers of water and expedite regulatory processes to assist in implementation of the plan consistent with legal requirements. The Governor's Panel will submit the plan to the Governor by December 2000.

2.2.5 Storage

Expanding water storage capacity is critical to the successful implementation of all aspects of the CALFED Program. Not only is additional storage needed to meet the needs of a growing population but, if strategically located, it will provide much needed flexibility in the system to improve water quality and support fish restoration efforts. Water supply reliability depends upon capturing water during peak flows and during wet years, as well as more efficient water use through conservation and recycling.

Actions Included in the Programmatic EIS/EIR

The Program identified actions that will be pursued in Stage 1 to expand storage capacity at existing reservoirs and strategically located off-stream sites by approximately 950 TAF, and to implement a major expansion of more environmentally sensitive groundwater storage for an additional 500 TAF to 1 MAF. CALFED Agencies are committed to increasing storage through the development of acceptable projects described below. Storage projects are not developed in

isolation but rather as part of an overall water management strategy. As such, storage combined with other program actions such as conservation, transfers and habitat restoration will contribute to and be compatible with the water supply reliability, water quality and ecosystem restoration program objectives. For example, storage projects must be constructed and operated in a manner that is consistent with CALFED's water quality goal of continuous improvement in Delta water quality. Local agencies will continue to independently develop storage projects to meet local needs.

The Final Programmatic EIS/EIR identified 12 potential surface reservoir sites and many possible groundwater storage sites. Based upon the work of the Integrated Storage Investigation and previous studies, DWR and Reclamation will work with other CALFED Agencies to take the necessary steps to pursue expansion of two existing reservoirs and construction of a new offstream reservoir, with a combined capacity of 950 TAF and a major expansion of groundwater storage for an additional 500 TAF to 1 MAF. DWR and Reclamation will also study two potential storage projects through partnerships with local agencies. However, these two additional sites will require substantial technical work and further environmental review and development of cost-sharing agreements before decisions to pursue them as part of the CALFED Program.

Project	Potential Storage (acre-feet)
In-Delta Storage	250,000
Enlarged Shasta	300,000
Expanded Los Vaqueros	400,000
Groundwater/Conjunctive Use	500,000-1,000,000
TOTAL	1,450,000 - 1,950,000

The remaining potential reservoir sites in CALFED's screened list of 12 sites, as well as those sites previously screened out earlier during the site review process, appear to have less potential for providing benefits during Stage 1 or soon thereafter, either because of cost, extensive planning and analysis required, or other factors. Some of these sites may be retained solely for analysis purposes and could serve as alternatives to the above projects. Future progress and experience with implementation of other parts of the Program, such as the EWA or south Delta conveyance improvements, may better define potential benefits of these storage projects. CALFED does not plan to pursue implementation of any of these projects at this time.

The benefits of increased water supply reliability resulting from actions to provide expanded storage (as well as to provide conveyance improvements, described in section 2.2.6) will be available to be shared among beneficial uses as appropriate to the specific action. In evaluating and allocating costs and benefits of CALFED storage and conveyance projects, actions taken outside the CALFED Program will not provide entitlements or the justification for claims for any

parties or class of beneficial users to any particular allocation of storage and conveyance assets developed through the CALFED Program.

Surface Storage Projects To Be Pursued With Project-specific Study. The CALFED Final Programmatic EIS/EIR identified as a list of twelve potential surface storage projects for consideration. Further project-specific review, however, will be required. Actions taken in Stage 1 will focus on the necessary feasibility studies and environmental review for implementing or proceeding with three surface storage projects. In addition, two reservoirs will need further study before the CALFED Agencies or their successor decides whether to proceed with those projects.

- **In-Delta storage project (approximately 250 TAF).** An in-Delta storage facility can provide both fishery benefits and enhanced water project flexibility. CALFED will explore the lease or purchase of the Delta Wetlands project. CALFED also may initiate a new project, in the event that Delta Wetlands proves cost prohibitive or infeasible.

  - Make decision as to whether to seek authorization for a feasibility study of alternatives (Federal funds) by October 2000.
  - Select project alternative and initiate negotiation with Delta Wetlands owners or other appropriate landowners for acquisition of necessary property by December 2001.
  - Develop project plan that addresses local concerns about effects on neighboring lands and complete any additional needed environmental documentation by July 2002.
  - Complete environmental review and documentation, obtain necessary authorization and funding, and begin construction by the end of 2002.

- **Expand CVP storage in Shasta Lake by approximately 300 TAF.** Such an expansion will increase the pool of cold water available to maintain lower Sacramento River temperatures needed by certain fish and provide other water management benefits, such as water supply reliability.

  - Resolve legal issues to allow State agency cooperation by the end of 2000.
  - Complete feasibility study and preliminary design by the end of 2003.
  - Complete environmental review and documentation, obtain Federal authorization and funding, and begin construction by the end of 2004.

- **Expand Los Vaqueros Reservoir by up to 400 TAF with local partners as part of a Bay Area water quality and water supply reliability initiative.** As part of a Bay Area initiative, an expanded Los Vaqueros Reservoir would provide water quality and water supply reliability benefits to Bay Area water users. As an existing reservoir operated by the Contra Costa Water District (CCWD), the Los Vaqueros Reservoir is subject to a number of mandates and agreements. DWR and

Reclamation will work with CCWD and interested stakeholders to assure that previous commitments, including local voter approval required for expansion, are respected.

- S Identify potential local partners and develop agreement with CCWD and other partners as needed for necessary studies by March 2001.
- S Secure authorization and funding for feasibility studies by July 2001.
- S Begin feasibility study and environmental review July 2001, complete feasibility study by July 2002.
- S Complete environmental review, documentation, and preliminary design on a selected alternative by the end of 2003.
- S Finalize agreements with project participants by mid-2004.
- S Obtain necessary authorizations and funding (including local voter approval) by the end of 2004, and begin construction by the end of 2005.

Surface Projects Requiring Further Consideration. In addition to the projects described above, CALFED will join local partners in Stage 1 to evaluate two additional surface storage projects. While these projects require extensive technical work, significant additional environmental review and development of cost-sharing agreements before a decision to implement the project as part of the CALFED Program.

- C **Sites Reservoir.** This project, with a capacity of up to 1.9 million acre-feet, could enhance water management flexibility in the Sacramento Valley. By reducing water diversion on the Sacramento River during critical fish migration periods, this project can greatly increase reliability of supplies for a significant portion of the Sacramento Valley. It can also provide storage and operational benefits for other CALFED programs including Delta water quality and the EWA.

  - S Develop joint planning program through an MOU with local water interests by October 2000.
  - S Complete environmental review and planning documentation by August 2004.

- C **250-700 TAF of additional storage in the upper San Joaquin River watershed.** It would be designed to contribute to restoration of and improve water quality for the San Joaquin River and facilitate conjunctive water management and water exchanges that improve the quality of water deliveries to urban communities. Additional storage could come from enlargement of Millerton Lake at Friant Dam or a functionally equivalent storage program in the region.

  - S Begin comprehensive study of alternatives by the end of 2000.
  - S Begin feasibility study on selected project by the middle of 2001.
  - S Complete environmental review and planning documentation by the middle of 2006.

Groundwater Storage Projects. CALFED Agencies will facilitate and fund locally supported, managed and controlled groundwater and conjunctive use projects with a total of 500 TAF to 1 MAF of additional storage capacity by 2007. Groundwater/conjunctive use projects will be implemented through locally supported and managed projects or through partnerships with local and regional interests. It is CALFED's intent to support voluntary, locally controlled groundwater projects which are designed to address local water needs first, before considering regional or statewide benefits. Groundwater quality will be an important criterion in the selection, operation and management of any of these locally controlled groundwater storage sites. These projects will include a combination of purchase, lease or sharing storage space with others, and will include consideration of existing groundwater storage facilities. CALFED has identified projects in the Sacramento Valley, near the Delta, the San Joaquin Valley and Southern California that could provide 500 TAF to 1 MAF of storage.

Stage 1 actions will include:

- Finalize agreements with new local project proponents for joint planning and development by February 2001.
- Begin feasibility studies by March 2001 with funding through CALFED and Proposition 13.
- Report on the performance of feasibility studies, implementable projects, and potential benefits and beneficiaries by the end of 2002. The report will separately identify likely local benefits as well as opportunities to benefit statewide water supply reliability and the EWA.
- Implement early stages of the most promising projects by the end of 2004. Aggressively pursue implementation of additional projects by the end of Stage 1.

Groundwater Management. Effective groundwater management programs are essential to the success of groundwater and conjunctive use projects, as well as to other CALFED programs such as water transfers and water quality. Currently, groundwater is managed in some areas of the State through adjudicated basins and by local water districts and agencies. While many of these districts and agencies have developed effective local groundwater programs, most groundwater basins in California are not managed to obtain the benefits that could be gained through conjunctive management of both groundwater and surface water. These benefits can include increased local water supply reliability, water quality protection, reduced subsidence, and mitigation of overdraft. CALFED believes that groundwater management at the sub-basin level will better protect groundwater resources while increasing local benefits that could be gained from conjunctive management. CALFED defines sub-basins as a portion of a groundwater basin delineated to reflect hydrologic or political boundaries. The sub-basin management system also would encourage local agencies to coordinate and integrate stakeholder-driven sub-basin management objectives while keeping intact the goals and elements of local plans. These objectives should include compliance with existing county ordinances and AB 3030 plans.

Therefore, CALFED Agencies will support legislation that encourages groundwater management at the sub-basin level.

AB 3030, which authorizes local agencies to enact voluntary groundwater management plans within their boundaries, is an important foundation for comprehensive groundwater management in California. AB 3030 also allows agencies to enter into agreements to develop basin-wide plans but does not require such basin-wide plans to be developed. DWR will adopt regulations for expenditure of grant and loan funds that make funding contingent upon local agencies having an AB 3030 plan or a functional equivalent in place. CALFED will work with local governments and affected stakeholders to develop legislation to strengthen AB 3030 and provide technical and financial incentives to encourage more effective basin-wide groundwater management plans, in part by conditioning future State funding for water programs on the development of local groundwater management plans by 2004.

Funding

The financing strategy for individual storage projects will vary due to the design and planned operations of each project. Final cost allocations, however, will be made based on the principle of "beneficiaries pay." Generally, the planning and feasibility stages of surface storage projects will be pursued with State and Federal public funding. If a project is determined to be feasible, a cost allocation plan will be prepared as part of the design phase, preliminary cost allocations secured before construction begins, and final cost allocation agreements implemented prior to project completion. The expected total investments in storage during Stage 1 will be approximately $1.4 billion.

Regulatory Compliance

All of the projects described above, as well as many other CALFED program actions, will need to comply with applicable regulatory programs. Potential surface storage projects being evaluated by CALFED will need to comply with, among other things, the requirements of the State and Federal ESA, the Clean Water Act Section 401 certification process, and the USACE regulatory permit program. CALFED has taken a number of steps to assure that the regulatory review process for storage projects proceeds in a timely manner. These steps are discussed in more detail in Section 3.

2.2.6 Conveyance

As indicated in the Preferred Program Alternative, the CALFED Agencies have chosen to pursue a through-Delta conveyance strategy. The CALFED Agencies therefore will take all reasonable actions to optimize the use of the Delta as the means for conveyance of State and Federal project export water.

The CALFED goal for Delta conveyance is to identify and implement conveyance modifications that will improve water supply reliability for in-Delta and export users, support continuous improvement in drinking water quality, and complement ecosystem restoration. More specifically for export and environmental purposes, conveyance improvements are needed to improve the pumping capabilities of SWP export facilities to: (1) restore water project reliability and operational flexibility; (2) allow the EWA to transfer and store water; (3) allow a reliable water transfer market to function; (4) allow SWP facilities to convey larger amounts of water during periods of high quality water in the Delta to improve water quality for urban use; and (5) provide greater capability for SWP facilities to be used to improve the reliability of CVP supplies for both its water users and wildlife refuges. DWR, Reclamation and USACE will lead efforts to implement these conveyance projects.

DWR and Reclamation will work with the other CALFED Agencies to pursue significant improvements in the water conveyance facilities in the Delta in Stage 1, which will be pursued through project-specific environmental review and permitting.

Actions Included in the Programmatic EIS/EIR

The following projects and actions were analyzed on a programmatic basis in the Final Programmatic EIS/EIR. As CALFED Agencies pursue project-specific environmental study, additional project-specific mitigation may be necessary.

> **South Delta.** The specific actions listed below are components of, or are directly related to, the "South Delta Improvement Program" which has been under study and development for a number of years. The CALFED Agencies intend for these actions in the South Delta to address the needs of the export projects, the Delta ecosystem and local, in-Delta agricultural water users. These components will go forward following the completion of project-specific environmental review and permitting. DWR will lead the CALFED Agencies in implementing these south Delta actions. Environmental review will be completed by the end of 2002. These actions, related to providing for more reliable long-term export capability by the SWP and CVP and protection of local diversions in the Delta, are in addition to historic and current efforts (including annual installation of temporary barriers as well as current year local dredging and diversion improvements).

- **Increase SWP pumping from the current limit from March 15 to December 15 to 8,500 cfs; and modify existing pumping criteria from December 15 to March 15 to allow greater use of SWP export capacity.** Increased pumping can be used to increase water supplies through restoring the SWP's operational flexibility as well as allow diversion of a larger proportion of water supplies in the Delta during periods of good water quality. SWP facilities are used first for SWP purposes, as provided for in SWP water supply contracts. Increased pumping capabilities will also increase opportunities to convey water for the CVP, the EWA and water transfers, since the availability of pumping capacity for non-SWP purposes is expected to increase under this action. Such increased pumping is conditional upon avoiding adverse impacts to fishery protection and in-Delta water supply reliability.

  - Complete environmental review by the end of 2002.
  - Secure appropriate regulatory permits by the middle of 2003 to increase pumping up to 8,500 cfs during periods that are currently restricted. This includes completing a project-specific operations plan that addresses the potential impacts of increased pumping. The operations plan will be developed through an open CALFED process. This pumping increase will increase export capability by up to 100,000 acre-feet per month depending on hydrological conditions, fisheries conditions and availability of storage south of the Delta.
  - Full use of this increased pumping capability will require continued implementation of temporary barriers on an annual basis as well as project-specific actions to protect agricultural diversions and navigation in the South Delta.

- **Increase SWP pumping to the maximum capability of 10,300 cfs.** This is to be accomplished through two sets of specific actions set forth below. As the South Delta Improvement Program is fully implemented through the end of Stage 1, the SWP export capability will increase to 10,300 cfs, greatly expanding benefits for all purposes. Full use of this capacity will depend on protection of agricultural diversions and navigation in the South Delta, hydrologic conditions, fisheries conditions, availability of storage south of the Delta, and use for non-SWP purposes.

  - **Design and construct new fish screens at the Clifton Court Forebay and Tracy pumping plant facilities to allow the export facilities to pump at full capacity more regularly.**

    < Complete funding plan by early 2003.
    < Complete facilities design by the middle of 2004.
    < Seek funding and authority to complete initial fish screens, and begin operations and performance testing by the middle of 2006.

- **Dredge and install operable barriers to ensure water of adequate quantity and quality to agricultural diverters within the South Delta.** This will include installation of an operable Grant Line Canal barrier, which will be constructed and operated in accordance with conditions and directions specified by USFWS, DFG and NMFS. In the interim prior to installation of permanent operable barriers, DWR would continue to install temporary barriers on an annual basis.

  - Complete funding plan by early 2003.
  - Complete facilities design by the middle of 2005.
  - Seek funding and authority to complete Head of Old River barrier by the end of 2006.
  - Seek funding and authority to complete Middle River barrier, Tracy barrier and Grant Line Canal barrier by the end of 2007.

- **Design and construct floodway improvements on the lower San Joaquin River to provide conveyance, flood control and ecosystem benefits.** USACE and DWR will work with the other CALFED Agencies to assure that the Comprehensive Study is consistent with this project.

  - Complete environmental studies by early 2003.
  - Complete project design and funding plan by early 2004.
  - Begin construction by the middle of 2005.

- **Reduce agricultural drainage in the Delta.** Actions to reduce such drainage will include early implementation of projects on Veale and Byron tracts to reduce or relocate major sources of drainage into South Delta channels. The purpose of these projects is to minimize elevated salinity and other constituents of concern to drinking water at urban intakes in the South Delta. These projects will be completed prior to completion of the installation of permanent barriers in Old River near the San Joaquin River, Grant Line Canal, Old River near Tracy and Middle River and before SWP pumping can increase to its full capacity of 10,300 cfs during periods that are currently restricted.

North Delta. CALFED will improve flood protection and conveyance facilities in the North Delta for water quality and fishery improvements, and avoid water supply disruptions. The improvements include:

- **Evaluate and implement improved operational procedures for the Delta Cross Channel to address fishery and water quality concerns.** Reclamation will lead this effort, in cooperation with the other CALFED Agencies, particularly the fishery agencies.

- S Begin operational studies (such as more intense fish monitoring on both sides of the Cross Channel, opening and closing the gates on tidal cycles, etc.) by October 2000.
- S Complete studies and make specific recommendations by the end of 2003.

C **Simultaneously evaluate a screened through-Delta facility on the Sacramento River of up to 4,000 cfs.** The diversion facility on the Sacramento River is an action to be considered only after three separate assessments are satisfactorily completed: first, a thorough assessment of Delta Cross Channel (DCC) operation strategies and confirmation of continued concern over water quality impacts from DCC operations; second, a thorough evaluation of the technical viability of a diversion facility; and third, satisfactory resolution of the fisheries concerns about a diversion facility. The lead agencies for this effort are DWR and Reclamation, in cooperation with the other CALFED Agencies. The historic emphasis has been on a screened diversion at Hood on the Sacramento River. This and other potential sites between and including Hood and Georgiana Slough will be considered as part of this evaluation. (The water quality section below discusses other related water quality actions and how this facility could fit into the broader water quality strategy.)

- S Develop specific study plan by October 2000.
- S Fund and begin studies through CALFED Agency appropriations by October 2000.
- S Complete water quality and fish effects studies and develop recommendations, taking into consideration the results of the Delta Cross Channel operational study above and evaluation of water quality measures, by the end of 2003.
- S Complete environmental review of recommended program. If fish protection conditions are met and facility is found to be necessary, seek funding and authority to begin construction by the end of 2007.

C **Design and construct floodway improvements in the North Delta (such as on the lower Mokelumne River and Georgiana Slough) to provide conveyance, flood control and ecosystem benefits.** The CALFED Agencies intend that final development and implementation of actions under the Comprehensive Study will be coordinated and consistent with the CALFED Bay-Delta Program.

- S Complete environmental studies by early 2003.
- S Complete project design and funding plan by early 2004.
- S Make decision whether to seek funding and authority to begin construction by the middle of 2005.

Interties. The CALFED Agencies will pursue a number of interties and bypasses in the water system.

- **An intertie between the SWP and CVP facilities at or near Tracy.** This short channel between the State and Federal canals would allow operators to take advantage of fluctuations in Delta water quality at the two project intakes, delivering higher quality to either project canal.

  - Complete environmental work and project design by the middle of 2004.
  - Complete funding plan by the middle of 2004.
  - Make decision whether to seek funding and authority to begin construction by the end of 2004.
  - Assess the connection of the CVP to the SWP's Clifton Court Forebay with a corresponding increase in the Forebay's screened intake.

Complementary Actions

The Framework identified the following actions, which were not analyzed in the Final Programmatic EIS/EIR and will, therefore, require additional environmental review:

- **Install and operate temporary barriers in the south Delta until fully operable barriers are constructed as the South Delta Improvements Program is implemented.** The purpose of this program is to increase water levels in the south Delta for agricultural irrigators in the area to ensure they have an adequate water supply for diversion until such time as a permanent south Delta solution is provided through implementation of other conveyance facilities identified in the South Delta Improvements Program. The Temporary Barriers Program (TBP) has been in place through 1991-2000. One of the barriers in the TBP is the spring Head of Old River barrier which is a critical component of the Vernalis Adaptive Management Plan, an action which the CALFED Agencies have identified for immediate implementation. The TBP is an annual activity requiring the preparation of environmental documentation, securing required regulatory and access permits, interagency coordination, monitoring, modeling, installation, operation and removal. This is ongoing, beginning in FY 2000-2001.

- **Take actions to protect navigation and protect local diverters in the south Delta who are not adequately protected by the TBP.** Although the south Delta barriers provide adequate protection to much of the south Delta, there are still some diverters who suffer from low water levels because they are downstream or located too far away from the barriers. Actions which need to be taken to protect these diverters may include: installation and operation of portable pumps, limited project-specific dredging of existing intakes, and/or project-specific modification to existing diversion structures including the conversion of siphons to pumps. This action requires preparing detailed plans at each diversion location, preparing permit applications, preparation of environmental documentation (as needed), securing applicable permits and funding and finalizing agreements with the diverter as to the scope of work to be done and funding of the work.

This work is ongoing, as needed, beginning in FY 2000-2001.

- **A bypass canal to the San Felipe Unit at the San Luis Reservoir.** When operated in conjunction with local storage, this canal would allow Santa Clara Valley Water District to receive water directly from the Delta pumping facilities, thereby avoiding water quality problems associated with the "low point" water levels in San Luis Reservoir. Resolving this "low point" issue also will increase the effective storage capacity in San Luis Reservoir up to 200 TAF.

  - Fund studies of bypass canal and related expansion of local storage through Proposition 13, allocate funds to Santa Clara Valley Water District, the implementing agency, by October 2000.
  - Complete environmental review and documentation and preliminary design by the end of 2003.
  - Obtain necessary authorization and funding and begin construction by end of 2004.

- **Facilitate water quality exchanges and similar programs to make high quality Sierra Nevada water in the eastern San Joaquin Valley available to urban Southern California interests.** The Metropolitan Water District of Southern California and the Friant Water Users Authority and its member agencies have commenced preliminary discussions to accomplish these objectives, as well as improving water supply reliability for the agricultural districts. DWR and Reclamation will work with the other CALFED Agencies and these two non-CALFED Agencies to assure that these efforts do not adversely affect ongoing consensus efforts to restore the upper San Joaquin River.

  - Initiate evaluations and studies of potential infrastructure improvements by December 2000.
  - Complete feasibility studies and implement selected demonstration projects by the end of 2001.
  - Complete environmental review and begin implementation of a long-term program, including necessary infrastructure, by the end of 2004.

- **Sacramento and San Joaquin Comprehensive Study.** USACE and the Reclamation Board are currently implementing a Comprehensive Study of the Sacramento and San Joaquin River watersheds to improve flood control efforts out to San Francisco Bay. The Delta and its ability to convey flood waters play a crucial role in the Comprehensive Study. The CALFED Agencies intend that final development and implementation of actions under the Comprehensive Study will be coordinated and consistent with the CALFED Bay-Delta Program.

Funding

CALFED anticipates that the cost of implementing the conveyance program improvements in Stage 1 will be approximately $1 billion.

2.2.7 Environmental Water Account

An essential goal of the CALFED Program is to provide increased water supply reliability to water users while at the same time assuring the availability of sufficient water to meet fishery protection and restoration\recovery needs as part of the overall ERP. As a means to achieving this, the CALFED Agencies will provide commitments under FESA and CESA for the first four years of Stage 1, which will be based on the availability of water from existing regulation, an EWA combined with the ERP, and the ability to obtain additional assets should they be necessary.

The EWA focuses on resolving the fishery/water diversion conflict at the CVP/SWP Delta export pumps because, in recent years, these diversions have suffered the greatest fluctuations in water supply reliability due to conflicts with fishery needs. The CALFED Agencies will continue working with other diverters in the Delta watershed to resolve local fishery-diversion conflicts based on the project-specific needs and opportunities for each diversion. The CALFED Agencies have crafted the EWA so that it has no effect on the water rights of other water right holders in the watershed.

Overall Purpose, Framework and Administration

The EWA has been established to provide water for the protection and recovery of fish beyond water available through existing regulatory actions related to project operations. The EWA is a cooperative management program whose purpose is to provide protection to the fish of the Bay–Delta estuary through environmentally beneficial changes in SWP/CVP operations at no uncompensated water cost to the projects' water users. This approach to fish protection requires the acquisition of alternative sources of project water supply, called the "EWA assets," which will be used to augment streamflows, Delta outflows, to modify exports to provide fishery benefits and to replace the regular project water supply interrupted by the changes to project operations. The replacement water will compensate for reductions in deliveries relative to existing facilities, project operations and the regulatory baseline (as defined below) that result from EWA actions.

USFWS, NMFS, DFG, Reclamation and DWR have established the EWA by executing the Environmental Water Account Operating Principles Agreement contemporaneously with this ROD. This summary should be interpreted to be consistent with the EWA Operating Principles Agreement. To the extent that the EWA Operating Principles Agreement provides greater specificity than or may be inconsistent with this summary, the EWA Operating Principles Agreement controls.

The EWA will provide additional protection for fish and provide support for a commitment not to reduce south of Delta project deliveries. The CALFED Agencies intend to use EWA assets for, among other things, extending pumping curtailments during critical periods for fish. As currently designed, the EWA would not be used to supply water to meet any new regulatory requirements under statutes other than FESA and CESA (such as new Federal Energy Regulatory Commission (FERC) or SWRCB instream flow requirements).

The EWA will be funded jointly by the State and Federal governments and will be authorized to acquire, bank, transfer, sell and borrow water and arrange for its conveyance. EWA assets will be managed by the State and Federal fishery agencies (USFWS, NMFS, and DFG) in coordination with project operators and stakeholders, through the CALFED Operations Group. Initial acquisition of assets for the EWA will be made by Reclamation and DWR. Subsequently, it is anticipated that acquisitions will be made pursuant to a public process that may capitalize upon the ability of other agencies or third parties to acquire assets.

Baseline Level of Protection. The EWA will provide for fishery protection actions that are supplemental to a baseline level of protection established by an existing set of regulatory programs. The baseline level of protection, identified as Tier 1 in the EWA discussion below, consists of:

- **1993 Winter-run Biological Opinion (NMFS)**

- **1995 Delta Water Quality Control Plan (SWRCB)**. At this time, SWP and CVP are responsible for meeting flow related objectives contained in this plan. The CALFED Agencies recognize that the SWRCB may adjust or reallocate the responsibilities for meeting the 1995 Delta Water Quality Control Plan standards, as part of its ongoing Bay-Delta Water Rights Hearing. Adjustment of responsibility to meet the standards will not affect the baseline level of protection for purposes of the EWA.

  Appropriate CALFED Agencies will develop a strategy to deal with the rare circumstances when the CVP obligation under the Water Quality Control Plan exceeds the 450 TAF annual cap for use of CVPIA Section 3406(b)(2) water. In the strategy, to be developed in conjunction with the Governor's Drought Contingency Plan, the Agencies will use their available resources to create an insurance policy that will seek to eliminate impacts to water users, while not adversely affecting other uses.

- **1995 Delta Smelt Biological Opinion (USFWS).** The export curtailment contained in the 1995 Delta Smelt Biological Opinion (item 2 on page 19), commonly referred to as the " 2 to 1 Vernalis flow/export ratio", will be met by Section 3406(b)(2) of the CVPIA and/or EWA. This objective calls for the SWP and CVP to reduce combined exports, below what is allowed in the 1995 Water Quality Control Plan during a 31-day period in April and May. The 1995 WQCP

allows exports to be 100 percent of the base San Joaquin River flow at Vernalis during the April-May pulse period. The SWP will be reimbursed by the EWA for its participation in reducing exports pursuant to the 2 to 1 Vernalis flow/export ratio.

The CVP and SWP will be operated pursuant to the terms of the San Joaquin River Agreement (SJRA) through 2011. While the SJRA is in effect, the exports may be reduced beyond what is called for by the 2 to 1 Vernalis flow/export ratio and San Joaquin River flows may be augmented by water acquired from upstream sources during that same time period. Such an augmentation will not be included as part of the SWP share of Vernalis flow. While operating pursuant to the SJRA, the SWP and CVP will also receive reimbursement from the EWA or pursuant to Section 3406(b)(2) for the additional curtailment. If the SJRA is not implemented for any reason, the operations will default back to the biological opinion operation, pursuant to the terms of the SJRA.

- **Full Use of 800 TAF Supply of Water Pursuant to Section 3406(b)(2) of the CVPIA in accordance with Interior's October 5, 1999 Decision, clarified as follows:** *Water Resulting from Refill of Reservoirs ("Reset")*: Water which is available under the (b)(2) Policy as a result of refill of reservoirs following upstream releases ("reset") will not be used in a manner which results in increased export reductions. Upstream releases of (b)(2) water pumped by the SWP and made available to the EWA will not be subject to the "reset" provision.

  Export Curtailments which Result in Increased Storage ("Offset"): Where a prescribed (b)(2) export curtailment results in a reduction in releases from upstream reservoirs and hence increased storage, the charge to the (b)(2) account will be offset to the extent that the increased storage will result in increased delivery (beyond forecast delivery at the time of the export curtailment) to south-of-Delta CVP contractors in the remainder of the water year. If such deliveries cannot be increased in that water year, such additional water stored in upstream reservoirs shall be available for other (b)(2) uses without charge to the (b)(2) account. Where the delivery to export users in the remainder of the water year will not be increased and end-of-year storage will be increased, there will be no offset to the charge to the (b)(2) account.

Other Environmental Protections. The regulatory baseline above also assumes that other environmental protections contained in statutes remain in place. These other environmental protections include without limitation Level 2 refuge water supplies, as required by the CVPIA. The CVP will use its share of the benefits from Joint Point of Diversion, to the extent available, to provide water required by its Level 2 refuge water supply mandates, but using such benefits will not create any limitation on the Level 2 supply available for refuges.

Asset Development. Immediate development of assets for the first year is critical to EWA success. Initial water purchases and lease of groundwater storage will be secured from willing sellers by the end of 2000. In addition to assets to be acquired annually, as shown in the table below, an initial one-time deposit of water equivalent to 200 TAF of south-of-Delta storage will be acquired from a variety of sources to assure the effectiveness of the EWA and provide assurances for SWP and CVP water supply/deliveries.

Borrowing agreements will allow the EWA to borrow water from the Projects for necessary actions during a water year as long as the water can be repaid without affecting the following year's allocations. To the extent practicable, borrowing from the SWP and CVP will be equitably shared. The limitations on borrowing are described in the EWA Operating Principles Agreement attached to this document.

Source shifting agreements with south-of-Delta water providers for 100 TAF will be used to enhance the effectiveness of the EWA, and to help provide assurance that SWP and CVP water deliveries and operations will not be affected by EWA operations. As CALFED develops new water, the EWA will obtain an appropriate share in order to minimize the need for annual acquisitions and to maximize operational flexibility.

ESA Commitments

As part of the MSCS Conservation Agreement and the FWS and NMFS biological opinions, the CALFED Agencies have provided a commitment, subject to specified conditions and legal requirements, that for the first four years of Stage 1, there will be no reductions, beyond existing regulatory levels, in CVP or SWP Delta exports resulting from measures to protect fish under FESA and CESA. This commitment is based on the availability of three tiers of assets:

> **Tier 1** is baseline water, provided by existing regulation and operational flexibility as described above. The regulatory baseline consists of the biological opinions on winter-run salmon and delta smelt, 1995 Delta Water Quality Control Plan, and 800 TAF of CVP Yield pursuant to CVPIA Section 3406(b)(2).
>
> **Tier 2** consists of the assets in the EWA combined with the benefits of the ERP and is an insurance mechanism that will allow water to be provided for fish when needed without reducing deliveries to water users. These assets are shown in the table on the preceding page. Tier 1 and Tier 2 are, in effect, a water budget for the environment and will be used to avoid the need for Tier 3 assets as described below.

Action Description	Water Available Annually (Average)
SWP Pumping of (b)(2)/ERP Upstream Releases [1]	40,000 acre-feet[2]
EWA Use of Joint Point[3]	75,000 acre-feet
Export/Inflow Ratio Flexibility	30,000 acre-feet
500 cfs SWP Pumping Increase	50,000 acre-feet
Purchases - South of Delta	150,000 acre-feet
Purchases - North of Delta[4]	35,000 acre-feet
TOTAL	380,000 acre-feet

Tier 3 is based upon the commitment and ability of the CALFED Agencies to make additional water available should it be needed. It is unlikely that assets beyond those in Tier 1 and Tier 2 will be needed to meet ESA requirements. However, if further assets are needed in specific circumstances, the third tier will be provided. In considering the need for Tier 3 assets, the fishery agencies will consider the views of an independent science panel. Although the CALFED Agencies do not anticipate needing access to Tier 3 of water assets, the CALFED Agencies will prepare an implementation strategy for Tier 3 by August 2001, establishing a timely scientific panel process and identifying tools and funding should implementation of Tier 3 prove necessary.

Implementation of the EWA and associated ESA commitments is not intended to affect the rights or obligations of third parties.

[1] The EWA and the SWP will share equally the (b)(2) and ERP upstream releases pumped by the SWP after they have served their (b)(2) and ERP purposes.

[2] The amount of water derived from the first four actions will vary based on hydrologic conditions.

[3] The EWA will share access to Joint Point of Diversion, with the CVP receiving 50% of the benefits.

[4] This is the amount of water targeted for the first year; higher amounts are anticipated in subsequent years.

2.2.8 Water Use Efficiency

The goal of the Water Use Efficiency Program is to accelerate the implementation of cost-effective actions to conserve and recycle water throughout the State. Water use efficiency measures are included in the CALFED Program for many reasons, including (a) water use efficiency investments can yield real water supply benefits to urban and agricultural users in the short term, especially compared to surface storage and major conveyance improvements that will take at least 5 to 10 years to complete; and (b) water use efficiency investments can generate significant benefits in water quality and timing of instream flows, even where they may not generate a net increase in available consumptively used water. Water reclamation provides additional opportunities to reduce water demand in a relatively cost-effective and environmentally-benign manner, with multiple benefits for efficiency, dry year reliability and discharge water quality. CALFED Agencies anticipate that significant investments in water use efficiency and water reclamation will be necessary during Stage 1 and beyond to address water supply demands caused by a rapidly increasing population and increased environmental water needs. These savings will be accomplished through incentive-based water use efficiency programs.

Water use efficiency potential varies significantly in California, depending on the region of the State and the sector involved. Working with the stakeholder steering committees and other technical experts, CALFED Agencies have developed ranges of estimated water savings during Stage 1. These estimates include only water that is currently unavailable for other uses because it is lost to excessive evaporation or drains to the ocean or some other unusable destination. In addition, approximately 225 to 310 TAF of water can be made available through water reclamation projects. These water savings would be generated as follows:

- 520 to 688 TAF in the urban sector
- 260 to 350 TAF in the agricultural sector
- 225 to 310 TAF in water reclamation projects

These estimates are not intended as targets, and focusing on potential water savings alone ignores the substantial contribution that water use efficiency investments can make to other CALFED program goals. Water savings estimates for urban uses are greater because water conservation savings are more cost-effective (given the higher cost of most urban supplies). Agricultural conservation opportunities exist but are more limited by financial capability and by the fact that a higher percentage of agricultural return flows are used by downstream users and are therefore not included in conservation estimates.

Incentive-Based Program

The primary CALFED program tool for encouraging investments in water use efficiency will be a competitive grant/loan program. This program, under the leadership of DWR, Reclamation, the SWRCB and NRCS, will identify and provide grants or cooperative agreements (with local cost share) or loans to the most promising water use efficiency projects, including:

- Urban water use efficiency measures.
- Agricultural water use efficiency measures.
- Water reclamation/recycling projects.

CALFED Agencies will rely on a competitive grant/loan program as the best mechanism to assure cost-effective investments in water use efficiency. Under this program, CALFED Agency investments will be made in the most cost-effective water use efficiency measures first. Due to the regional differences in water use efficiency potential, the exact cost-effective measures will vary. For example, in some agricultural districts the cheapest improvements may be to install automated delivery systems, while other districts may find channel improvements or canal lining productive. Similarly, differences exist statewide in the urban sector. Some agencies may focus on low-flow device retrofits, while others may have substantial opportunities for using reclaimed water. CALFED Agencies anticipate that the competitive grant/loan program would allow participating entities to effectively respond to local conditions.

Each grant/loan package will include tailored requirements for performance and accountability. The program would be used primarily as a capitalization mechanism; the ongoing obligations for operation and maintenance would be assumed by the participating agency. By using a competitive grant/loan program approach, water users and the program can respond to changes in the water supply picture over time. As water demands increase in the State as anticipated, and the most cost effective water use efficiency measures have been implemented, water users and the grant/loan program would increasingly turn to the more expensive water use efficiency measures.

Two elements will be critical to the success of a CALFED grant/loan program:

- Water agencies must implement water use efficiency measures that are cost-effective and appropriate at the local level. This level of attainment will be defined by agency compliance with the AB 3616 Agricultural Water Management Plans (for agricultural districts) or implementation of applicable Urban Water Conservation Council "best management practices" (for urban districts). CALFED Agencies anticipate that State and Federal assistance to agencies to attain this base level of water use efficiency will generally be in the form of technical assistance and capitalization loans, not grants. In addition, access to further CALFED Water Use Efficiency Program benefits (e.g., grants) will be conditioned on agency implementation of the applicable water management plans.

- Additional CALFED investments in water use efficiency are premised on the fact that some water use efficiency measures may not be cost-efficient when viewed solely from a local perspective, but may be cost-effective when viewed from a statewide perspective, compared to other water supply reliability options. In this case, CALFED Agencies anticipate a larger State and Federal assistance share in the form of grants. CALFED Agencies' proposed grant/loan program will tailor specific grants or loans to reflect this distinction between local benefits and statewide benefits, and will adjust the required local cost-share requirements accordingly.

The CALFED Agencies will support water use efficiency actions that also provide economic and other benefits to disadvantaged communities by ensuring they have a role in implementing such programs, both in the agricultural and urban sectors. Examples include not only toilet retrofit programs such as those undertaken by community-based organizations in Los Angeles, but also toxics reduction and pollution prevention programs that are linked to water use efficiency and wastewater reduction, and multilingual irrigator training programs.

Actions Included in the Programmatic EIS/EIR

Stage 1 actions of the Water Use Efficiency Program include:

- CALFED Agencies will prepare a program implementation plan, including a proposed organizational structure consistent with the overall CALFED governance structure, responsibilities for technical assistance programs and the grant/loan program, and evaluation procedures, by December 2000. In developing the grant/loan program, CALFED Agencies will consider the particular circumstances of the different program elements, as well as the ongoing stakeholder forums. These forums include the Agricultural Water Management Council, California Urban Water Conservation Council, the steering committees providing guidance to CALFED Agencies in the agricultural, urban and recycling programs, as well as the public advisory committee described below. The program implementation plan will include:

    - Incentives in the agricultural sector that will consider several factors, including: (i) the potential for reducing irrecoverable water losses; (ii) potential for attaining environmental and/or water quality benefits from WUE measures; (iii) regional variation in water management options and opportunities; (iv) availability and cost of alternative water supplies; and (v) whether the water needs of the recipient area can be satisfied from existing sources. Many of these factors are included in the quantifiable objectives being developed in the CALFED process by the agricultural water use efficiency steering committee stakeholder process, and CALFED Agencies anticipate that these quantifiable objectives will be an important factor in prioritizing expenditures under the agricultural incentive program.

    - Incentives in the urban sector that will focus on implementing the urban MOU process and on identifying and implementing measures that are supplemental to BMPs and are cost effective from a statewide perspective.

    - Incentives in the water reclamation area that will recognize the importance of regional water recycling programs, such as the Bay Area regional water recycling program and the Southern California comprehensive water reclamation and reuse study. CALFED Agencies will work with stakeholders to create cost-effectiveness criteria, building on approaches that have been previously developed for regional water recycling programs, that will guide the incentive program for water

reclamation.

- **S** A recognition and plan for addressing the need to make financial allocations in the incentive programs in the early years of implementation, in advance of approvals and/or certifications by the applicable Urban or Agricultural sector councils.

- C Within one year from the adoption of this ROD, CALFED Agencies will establish specific milestones, and associated benefits, remedies and/or consequences to track and guide the implementation of the Agricultural Water Use Efficiency Program. CALFED Agencies will put in place a process, structured to include the involvement and buy-in of interested parties (stakeholder and agency), to accomplish this work. The process will build on the work already begun by the Agricultural Water Use Efficiency Steering Committee.

- C The CALFED Agencies will develop a detailed finance proposal for Stage 1, including an evaluation of local cost share potential, no later than July of 2001. Recognizing that funding for the Water Use Efficiency Program will necessarily come from many different State and Federal sources, CALFED Agencies will assure that the Water Use Efficiency Program has sufficient resources for vigorous programs in each of the agricultural, urban, and water reclamation sectors.

- C DWR and Reclamation will work with the Urban Water Conservation Council and Agricultural Water Management Council to provide technical assistance to urban agencies and agricultural districts developing management plans under the Urban Water Management Planning Act and the AB 3616 process. This effort, when combined with efforts of NRCS and California Department of Food and Agriculture, will in the first four years of Stage 1 provide $34 million in technical assistance to districts and agencies in meeting their Council-endorsed or certified management plans.

- C The Department of the Interior will create a public advisory committee, as part of the new FACA committee, to advise State and Federal agencies on structure and implementation of assistance programs, and to coordinate Federal, State, regional and local efforts for maximum effectiveness. We anticipate that this advisory committee will include representatives of the agricultural, urban, and recycling steering committees, local agencies, and local farmworker organizations. The advisory committee will be established by December 2000.

- C By the end of 2002, CALFED Agencies will implement a process for certification of water suppliers' compliance with the terms of the urban MOU, including implementation of best management practices for urban water conservation. CALFED Agencies will support ongoing efforts of the California Urban Water Conservation Council to address this issue.

- C In addition to the annual evaluations of program progress, by December of 2004 CALFED Agencies will conduct a comprehensive evaluation of the Program's first 4 years, and will make appropriate additional State and Federal investments and actions to assure continued

aggressive implementation of water use efficiency measures in the State.

Water Measurement and Transfer Incentive Actions

Diverse stakeholder groups have recognized the importance of, and need for, appropriate measurement of water deliveries. Measurement will provide better information on statewide and regional water use, enable water purveyors to charge for water according to the amount used, allow water users to demonstrate the effects of efficiency measures, and facilitate a water transfers market. CALFED Agencies have initiated a public process to add greater definition to "appropriate measurement":

- An independent review panel on appropriate measurement will be convened. This panel will provide guidance that will help define appropriate measurement as it relates to surface and groundwater usage. The panel will prepare a consensus definition of appropriate measurement by the end of 2001.

- At the completion of this stakeholder/technical process, CALFED Agencies will work with the California State Legislature to develop legislation for introduction and enactment in the 2003 legislative session requiring the appropriate measurement of all water uses in the State of California.

Complementary Actions

CALFED Agencies believe that in order to promote water use efficiency measures in the agricultural sector, end users need to be able to beneficially participate in an active water transfer market. CALFED Agencies recognize that one barrier to an effective water transfer market is the lack of incentive for individual landowners to utilize available water conservation technologies because any water savings frequently accrue not to the landowner but to the irrigation district or water supply agency. CALFED Agencies will develop and support proposals to remove this disincentive to voluntary implementation of water use efficiency improvements.

Funding

CALFED Agencies have worked with the stakeholder steering committees, technical experts and practitioners to develop cost estimates associated with water use efficiency measures and water reclamation. Based on this outreach effort and evaluation, CALFED Agencies have estimated that achieving the potential water savings above would require an investment by the State and Federal governments in the range of $1.5 to $2 billion over the seven years of Stage 1. These funds, which will be allocated to local entities in the form of grants and/or loans for water use efficiency projects, will be matched with local or private funds on a project-by-project basis. During the first four years of Stage 1, CALFED Agencies propose State and Federal government investment

of $500 million, with an additional $500 million coming from local matching funds. This cost share provides an overall Stage 1 allocation, but individual project cost-shares may vary depending on the detailed finance proposal being developed and the nature of the projects developed by local agencies.

A water use efficiency program of this magnitude is aggressive and unprecedented nationally. CALFED Agencies strongly endorse this aggressive program as part of a broad CALFED Program designed to address California's water supply needs for the future. At the same time, given the uncertainties of implementing such an ambitious program, CALFED Agencies believe it will be appropriate to carefully evaluate the ongoing progress of the Program as it gets off the ground. CALFED Agencies will require annual reports from implementing agencies describing the progress of implementation efforts. These reports should include an ongoing evaluation of the availability of local cost-share financing and program effectiveness, and should include recommendations on removing any impediments to aggressive program implementation. CALFED Agencies anticipate that these annual reports will serve as a guide to subsequent year investments and program refinements. In addition, at the end of the first four years of Stage 1, CALFED Agencies will prepare a more comprehensive evaluation of program implementation. At that time, it may increase or reduce the targeted conservation goals to reflect actual implementation experience, redirect investments within the Water Use Efficiency Program to achieve the most effective results, and/or introduce new programs as necessary and appropriate.

The Stage 1 investments reflect the fact that many of the water use efficiency measures can be brought on line in a relatively short time frame, so that both planning and construction/capital costs are included earlier in Stage 1. Comparing water use efficiency investments on an "annual cost basis" (that is, taking the capital costs and operating costs and amortizing them over the expected life of the project) is a common way to evaluate the cost-effectiveness of water management investments. For example, costs of most of the water use efficiency measures evaluated by CALFED Agencies in the urban sector range from $150 to $450 per acre-foot per year. Under the competitive grant/loan program, the cheaper measures would be employed first.

Initial State and Federal funding for Stage 1 water use efficiency programs outlined in this section are identified within Proposition 204, Proposition 13, the CVPIA, the Reclamation Reform Act, Title XVI of P.L. 102-575, and various accounts in the Federal Farm Bill and related NRCS appropriations. Funding for the completion of the Water Use Efficiency Program will be determined through the Legislative and Congressional budget processes. The CALFED governing body will determine additional funding needs by the middle of 2004, which will be based upon the results of the program review and stakeholder input. Future funding, if necessary, may be sought through a bond measure that may also fund other out-year costs of the CALFED Program.

2.2.9 Water Quality

CALFED's Water Quality Program goal is to provide good water quality for the millions of Californians who rely on the Delta for all or a part of their drinking water. Current drinking water quality problems vary significantly by water agencies, depending on the agency's particular water sources. For example, the Metropolitan Water District of Southern California (MWD) and other Southern California utilities obtain water from the Delta via the State Water Project. MWD also receives highly saline Colorado River water which is then blended with Delta water. High levels of salinity are a major water quality problem for MWD, as are elevated levels of bromide and organic carbon. Salinity makes water taste bad and inhibits effective water recycling programs. Bromides and organic carbon interact with disinfection agents used in water treatment to create hazardous "disinfection byproducts" with potential adverse health effects.

In comparison, the Santa Clara Valley Water District, which is connected to both the Federal project (at San Luis Reservoir) and the State Water Project (via the South Bay Aqueduct from Clifton Court) shares the MWD concerns about salinity in Delta water, but may be even more sensitive to algal problems caused by low water levels in the San Luis Reservoir. The Contra Costa Water District takes its water directly from the Delta, and is highly sensitive to variations in Delta water quality. The North Bay Aqueduct of the SWP suffers from water quality problems during winter runoff periods. East Bay Municipal Utility District (EBMUD) and San Francisco get most of their water from the Sierra Nevada mountains, so they are less affected by Delta water quality. These differing situations for different water agencies require multifaceted approaches to drinking water quality that involve combinations of source water improvement, innovative and collaborative water management, and treatment options.

CALFED Agencies have adopted a general target of continuously improving Delta water quality for all uses, including in-Delta environmental and agricultural uses. Program actions designed to improve water quality to protect environmental uses are generally included in the Ecosystem Restoration Program (ERP) discussed above. For the drinking water quality program, CALFED Agencies have developed a specific goal based upon extensive stakeholder and agency involvement. CALFED Agencies' target for providing safe, reliable, and affordable drinking water in a cost-effective way, is to achieve either: (a) average concentrations at Clifton Court Forebay and other southern and central Delta drinking water intakes of 50 ug/L bromide and 3.0 mg/L total organic carbon, or (b) an equivalent level of public health protection using a cost-effective combination of alternative source waters, source control and treatment technologies.

CALFED Agencies will aggressively pursue a mix of strategies in order to improve in-Delta water quality. Program actions to address the drinking water quality concerns of the more than 22 million Californians who rely on Delta water fall into four broad categories. These actions will:

- Enable users to capture higher quality Delta water for drinking water purposes.
- Reduce contaminants and salinity that impair Delta water quality.
- Evaluate alternative approaches to drinking water treatment to address growing concerns over disinfection byproducts and salinity.

- Enable voluntary exchanges or purchases of high quality source waters for drinking water uses.

None of these actions, by itself, can assure adequate supplies of good quality drinking water for California. They must all be pursued, in conjunction with other CALFED actions such as conveyance and storage improvements, to generate significant improvements in drinking water at the tap. The responsibility for drinking water protection in the Bay-Delta ecosystem is shared by the State Department of Health Services (DHS), CalEPA (including the State Water Resources Control Board and the CVRWQCB) and DWR, with EPA providing funding and technical assistance. In particular, the CVRWQCB, with support from the CALFED agencies and DHS, is currently developing a comprehensive drinking water policy for Delta and upstream tributaries. The CALFED agencies will continue to coordinate drinking water protection efforts, with particular attention to ensuring fair treatment for communities of color and of lower socio-economic status by engaging and supporting local communities and stakeholders who are actively seeking to address water quality issues through pollution prevention, monitoring, and education activities.

The CALFED Agencies will seek to maintain the quality of existing and potential sources of drinking water supply, both groundwater and surface water. Specifically, before any locally controlled groundwater storage facilities are slated for storage of water supplies for local drinking water use, the CALFED Agencies will work with those communities to identify the sites with the lowest possible level of contaminants of concern and to identify the best quality sources economically available.

In response to recent conflicts between Delta water quality, water supply and fishery protection measures, in February 2000, CALFED Agencies developed and implemented an operations management coordination process. As described in the governance section, CALFED Agencies will continue to apply that process to Delta operations. CALFED Agencies believe this process, using the Operations Group and Water Operations Management Team, will assure concurrent consideration of water quality, fisheries and water supply in water project operations.

Actions Included in the Programmatic EIS/EIR

The CALFED Agencies will implement the following major elements of the Water Quality Program:

C **Address drainage problems in the San Joaquin Valley to improve downstream water quality.** This will include implementing recommendations from the San Joaquin Valley Drainage Program, identifying and supporting innovative drainage management programs, and supporting voluntary land retirement programs for drainage impaired lands, with local sponsorship. This includes CALFED actions, which target approximately 35,000 acres of land retirement, as well as complementary land retirement actions under other programs such as CVPIA. Actions include:

- S Finalize State Basin Plan Amendment and Total Maximum Daily Load for salinity in the lower San Joaquin River by the end of 2001.
- S Begin implementation of appropriate source control measures (e.g., on farm and district actions, development of treatment technology, real-time management and reuse projects such as agroforestry) by the end of 2003.

Reclamation is responsible for providing drainage service as required by the San Luis Act for its San Luis Unit contractors on the westside of the San Joaquin Valley and will be considering a range of options for continued work to resolve the drainage issues in that area.

C **Implement source controls in the Delta and its tributaries.** The CALFED Agencies with the assistance of the Department of Health Services will coordinate a comprehensive source water protection program. This program will include identification and implementation of appropriate pollutant source control measures, focused regulatory and/or incentive programs targeting pollutants of concern, development of a monitoring and assessment program, and infrastructure improvements to separate drinking water intakes from irremediable sources of pollutants.

- S CVRWQCB, with support from the CALFED Agencies and DHS, will establish a comprehensive State drinking water policy for Delta and upstream tributaries by the end of 2004.
- S As part of the CALFED Science Program, develop a comprehensive monitoring and assessment program by the beginning of 2003.
- S Evaluate and determine whether additional protective measures (regulatory and/or incentive-based) are necessary to protect beneficial uses by the end of 2004.
- S Consistent with the above policy, CVRWQCB, with support from DWR and DHS, will begin implementation of appropriate source control measures (e.g., advanced wastewater treatment, local drainage management practices) by the end of 2006.

C **Support the ongoing efforts of the Delta Drinking Water Council or its successor** to develop recommendations to the CALFED Agencies on treatment, alternative water sources, conveyance improvements, storage and operations necessary to meet CALFED's goal of continuous improvement in Delta water quality for all uses. The Council will rely in part on the results of a nationwide multi-year, $200 million, multi-stakeholder evaluation program led by the EPA to determine future standards and cost-effective treatment technologies, as well as the findings of the Independent Science Board and science panels. The Council will advise the CALFED Agencies on the composition of science panels related to drinking water. Actions include:

- S Council will complete initial assessment of progress toward meeting CALFED water quality targets and alternative treatment technologies by the end of 2003.
- S Council will complete final assessment and submit final recommendations on

progress toward meeting CALFED water quality targets and alternative treatment technologies by the end of 2007.

C **Invest in Treatment Technology Demonstration.** Recent private sector efforts have generated substantial advances in treatment technologies. The CALFED Agencies will encourage these technologies by funding a demonstration project to design and operate an ultra-violet disinfection plant, as well as other demonstration projects to design and operate desalination facilities for agricultural drainage using membrane treatment technology and focusing on management of brines and on-site waste stream management. Other promising treatment technologies that arise during the Program may be funded as well.

- S Initiate UV disinfection plant demonstration project by the end of 2002.
- S Initiate regional desalination demonstration project by the end of 2002.
- S Evaluate practicability of and determine timelines for full-scale implementation by the beginning of 2007.

C **Control runoff into the California Aqueduct and other similar conveyances.** Much of the land surrounding the southern portions of the California Aqueduct is used for agriculture and grazing. A number of agricultural drains directly impact the Aqueduct, and large stretches of the Aqueduct are not adequately protected from stormwater runoff that is impaired by soil erosion or agricultural and livestock runoff. Other major drinking water conveyance channels have similar runoff problems. The CALFED Agencies will implement appropriate physical modifications and watershed programs to correct these problems.

- S Initiate comprehensive evaluation of necessary physical modifications (e.g., modifications to berms, bypasses, and stormdrains to divert stormwater away from and prevent its discharge into the Aqueduct and other similar conveyance channels) by the end of 2001.
- S Develop and implement watershed programs adjacent to appropriate conveyance channels by the beginning of 2004.
- S Identify and begin implementation of necessary physical improvements by the end of 2005.

C **Address water quality problems at the North Bay Aqueduct.** The North Bay Aqueduct suffers from high total organic carbon and turbidity from local watershed runoff. Ongoing studies are investigating land-use "best management practices" (BMPs).

- S Provide funding to implement BMPs to improve watershed runoff water quality by the end of 2002.
- S By the end of 2003, study feasibility of relocating North Bay Aqueduct intake.

- **Study recirculation of export water to reduce salinity and improve dissolved oxygen in the San Joaquin River.** Exporting water from the Delta through the CVP and SWP at volumes greater than what is needed can establish additional flows in the San Joaquin River that could be used for salinity reduction and improving dissolved oxygen in the river.

  - Develop a workplan by October 2000.
  - Initiate the feasibility study of recirculation of water exported from the Delta through State and Federal water projects by the end of 2000.
  - Provide a recommendation to the CALFED governing body on the use of recirculation to meet CALFED objectives by the end of 2002. The recommendation will include analysis of impacts and benefits, and recommendations on infrastructure improvements necessary to implement recirculation should it be appropriate.

Complementary Actions

The Framework identified the following actions which were not analyzed in the Final Programmatic EIS/EIR and will, therefore, require additional environmental review.

- **Establish a Bay Area Blending/Exchange project.** The CALFED Agencies will implement a project that enables Bay Area water districts to work cooperatively to address water quality and supply reliability concerns on a consensual basis. As noted above, water supply agencies in the Bay Area have different water sources and different water supply and water quality concerns. This is an "umbrella" project that will evaluate a range of potential changes to existing infrastructure and institutional arrangements to encourage a regional approach to water supply operations. An example is the possibility of building "interconnects" between agency supply aqueducts, so that water suppliers can take advantage of different sources when water quality is highest (e.g., existing and/or additional Sierra Nevada mountain sources). These interconnects could be more effective if used in conjunction with an expanded Los Vaqueros Reservoir, discussed above in the storage section. Another example is to arrange local water transfers, where one district pays for water conservation measures in another district in exchange for some or all of the saved, presumably higher quality water. Some reviews that may have relevance to a Bay Area Blending /Exchange project already are underway in different contexts. For example, a supplemental EIS is being prepared to analyze potential alternatives related to East Bay MUD's contract with the Bureau of Reclamation. The Bay Area Blending/Exchange project is complementary to actions in the CALFED programmatic documents, and would help achieve objectives for water quality and water supply reliability, consistent with the CALFED solution principle of no significant redirected impacts.

  - Identify potential local partners and develop agreements as needed for necessary studies by July 2001.
  - Secure authorization and funding for feasibility studies by July 2001.

- S Begin feasibility study and environmental review by July 2001, complete feasibility study by July 2002.
- S Complete environmental review, documentation and preliminary design on a selected alternative by the end of 2003.
- S Finalize agreements with project participants by mid-2004.
- S Obtain necessary authorizations and funding (including any required local voter approval) by the end of 2004, and begin construction by the end of 2005.

C **Facilitate water quality exchanges and similar programs.** The CALFED Agencies will support efforts, consistent with overall CALFED principles**,** to make high quality Sierra Nevada water in the eastern San Joaquin Valley (e.g., San Joaquin River, Kings River, Kern River, and/or their tributaries) available to urban Southern California interests. The Metropolitan Water District of Southern California and the Friant Water Users Authority and its member agencies have commenced discussions to explore ways to accomplish these objectives, as well as improving water supply reliability for the agricultural districts. The CALFED Agencies will work to assure that these efforts do not affect ongoing consensus efforts to restore the upper San Joaquin River.

- S Initiate evaluations and studies of current capabilities and potential infrastructure improvements by December 2000.
- S Complete feasibility studies and identify initial projects, if any, by the end of 2001.
- S If agreement is reached by the parties involved, complete environmental review and begin implementation of a long-term program, including necessary infrastructure, by the end of 2004.

C **Develop and implement within two years a plan to meet all existing water quality standards and objectives for which the State and Federal water projects have responsibility.**

Funding

CALFED Agencies propose investing approximately $950 million during Stage 1 in water quality programs. Of this investment, more than $500 million would come from State and Federal sources and the remainder from local sources. Sources of Federal funding, in addition to future direct appropriations, include State direction of a portion of its share of Federal Safe Drinking Water Act State Revolving Fund (SRF), Clean Water Act Section 319 funds, Clean Water Act SRF and other Federal grant programs under State control. The State may use these funding sources, as available, in accordance with applicable criteria. The State's budget for FY 2000-01 includes more than $68 million from the Proposition 13 Interim Reliable Water Supply and Water Quality Program for water quality improvement projects. Additional Proposition 13 funds will be available during Stage 1 from the Safe Drinking Water, Flood Protection Corridor, Urban Streams Restoration, Watershed Protection, Nonpoint Source Pollution Control, Clean Water, and Water Recycling programs to fund projects with water quality benefits.

2.2.10 Water Transfers

The transfer of water between willing sellers and buyers represents an economically and environmentally sound part of the State's water strategy. Voluntary water transfers provide an important water resource management tool by fostering efficient allocation of water resources throughout the State. In some areas, local water transfers are common and CALFED Agencies will continue to support such local transfers. The successful implementation of the CALFED Program depends upon access to California's major water transportation systems and removing other barriers to transfers: physical, institutional and legal. Therefore, the goal of the CALFED Water Transfer Program is to encourage the development of a more effective water transfer market that facilitates water transfers and streamlines the approval process while protecting water rights, environmental conditions, and local economic interests.

Actions Included in the Programmatic EIS/EIR

Success of the CALFED Water Transfer Program will require the adoption of a comprehensive and progressive water wheeling policy that will require the enactment of State legislation to establish clear and concise laws governing access to and the cost of conveyance facilities as well as providing clear definitions of applicable rules and regulations.

In order to facilitate an efficient water market, DWR, SWRCB and Reclamation will focus on implementing the following elements:

- **Increase the availability of existing facilities for water transfers.** It is necessary to encourage and promote water transfers by facilitating "wheeling" transactions. Such transactions are paramount to the ultimate success of CALFED. Therefore, if legislation is not enacted during the 2000 legislative year to clarify the State's wheeling laws, the State administration will sponsor legislation in 2001.

- **Lower transaction costs through permit streamlining**. The CALFED Agencies propose to develop streamlined transfer approval procedures for certain kinds of transactions (intra-regional transfers, short-term transfers, dry-year transfers). This streamlining would include "pre-certification" of certain classes of transfers (e.g. local transfers) and expedited environmental review procedures and may necessitate legislation to implement. Actions include:

    - Convene a panel of stakeholders, including both transfer supporters and community representatives with concerns about transfers, to draft recommendations for a streamlined transfer approval process by December 2000.
    - Introduce legislative changes by April 2001.

A more active water transfer market heightens concern about the clarity of policies and procedures and the potential for third-party impacts. To respond to this and other concerns regarding better access to market information, CALFED Agencies are developing the "On-Tap" on-line water transfer information source, which will clarify application of policies and procedures and provide up-to-date information about ongoing transfer activity. This increased market information will reduce applicant and regulatory confusion and will allow third parties, including local communities, to track water transfers that may affect them and identify related outcomes from those transfers. Milestones include:

- Provide operational On-Tap website by the end of 2000.
- Establish California Water Transfers Information Clearinghouse to disseminate information on groundwater impacts, cumulative impacts and local socioeconomic impacts of transfers by the end of 2001.

Complementary Action

The Framework identified the following action which was not analyzed in the Final Programmatic EIS/EIR and will, therefore, require additional environmental review.

CALFED Agencies believe that in order to promote water use efficiency measures in the agricultural sector, end users need to be able to beneficially participate in an active water transfer market. CALFED Agencies recognize that one barrier to an effective water transfer market is the lack of incentive for individual landowners to utilize available water conservation technologies because any water savings frequently accrue not to the landowner but to the irrigation district or water supply agency. CALFED Agencies will develop and support proposals to remove this disincentive to voluntary deployment of water use efficiency improvements.

2.2.11 Levees

The goal of the CALFED Levee System Integrity Program is to provide long-term protection for multiple Delta resources by maintaining and improving the integrity of the extensive Delta levees system. CALFED proposes investing a total of approximately $450 million in Stage 1.

The Delta covers 738,000 acres of productive farmland and wildlife habitat interlaced with hundreds of miles of waterways. Much of this land is below sea level. Eleven hundred miles of levees are needed to protect Delta land uses including 520,000 acres of farmland, the Mokelumne Aqueduct that crosses the Delta to serve water to the East Bay, three State highways, a railroad, natural gas and electric transmission facilities, and thousands of acres of habitat. Levees also protect water quality for Delta and export users. If a levee fails, salt water from the Bay can inundate land that is below sea level, which can seriously affect Delta water supplies for months.

The CALFED Agencies propose substantial efforts during Stage 1 to rebuild certain levees in

ways that encourage habitat for aquatic and terrestrial species. These efforts are being undertaken consistent with the Ecosystem Restoration Program and are discussed under that heading, as well as under the Conveyance Projects section. DWR and USACE will lead the CALFED Agencies in implementing the Levee System Integrity Program. Where necessary, the Reclamation and USACE will seek Congressional authorization for Delta levee improvements. The Levee System Integrity Program consists of these elements:

- **Base Level Protection.** The Program will provide base level funding to help local reclamation districts reconstruct all Delta levees to a base level of protection (the "PL 84-99 standard). Currently, about 520 out of 1,100 miles of Delta levees do not meet this standard. During Stage 1, about 200 additional miles of levee will be brought up to a base level of protection.

- **Special Improvement Projects.** This Program will enhance stability on levees that have particular importance in the system. Priorities include life and personal property (more than 400,000 people live in Delta towns and cities) water quality (preventing salinity intrusion), protecting agricultural production, and protecting ecosystems.

- **Levee Subsidence Control Plan.** Draining and cultivation of Delta marsh lands causes the peat soil to break down and compact. Over time, land has subsided from sea level so that today two-thirds of the Delta is below sea level and subject to flooding. Some points are now 21 feet below sea level. CALFED will develop "best management practices" to control and reverse subsidence and work with local districts and landowners to implement cost-effective measures.

- **Levee Emergency Response Plan.** This will enhance the ability of local, State, and Federal agencies to rapidly respond to levee emergencies.

Levees in the Suisun Marsh have been included within the scope of the Levee System Integrity Program for purposes of considering whether levees within the Suisun Marsh may need repair or improvement to accomplish other CALFED objectives (e.g., ecosystem restoration). However, the CALFED Agencies do not intend to accept any responsibility or provide any assurance for maintaining the stability of Suisun Marsh levees through their inclusion in the Levee System Integrity Program. This does not preclude any existing CALFED Agency agreements and commitments for Suisun Marsh levee maintenance.

While the CALFED Agencies may fund repairs or improvements for levees throughout the solution area, the CALFED Agencies do not intend that any levee not already deemed eligible for the non-Federal Flood Control Work rehabilitation program be converted into an eligible non-Federal Flood Control Work levee as a consequence of this ROD, and do not intend to seek legislation that would convert any existing levee into an eligible non-Federal Flood Control Work, as part of the CALFED Levee System Integrity Program. This does not constrain any CALFED Agency from implementing existing levee repair or improvement programs in the CALFED solution area.

Actions Included in the Programmatic EIS/EIR

Stage 1 actions for the CALFED Levee System Integrity Program include:

- Initiate actions to refine the Delta Emergency Management Plan by 2000.
- Develop a Delta Risk Management Strategy that identifies risks to Delta levees, evaluates consequences, and recommends actions by 2001.
- Develop Best Management Practices for the reuse of dredged materials by 2001.
- Institute a program for using bay and Delta dredge material to repair Delta levees and restore Delta habitat, targeting 2 million cubic yards of dredge material applied in Stage 1. This program must be coordinated with CVRWQCB and other interested agencies to assure that the dredge material reuse program adequately addresses concerns over salinity and the quality of dredge material. An aggressive protective dredge material reuse program will be critical to the success of both the base level program and special improvement projects.

Complementary Action

The Framework identified the following actions which was not analyzed in the Final Programmatic EIS/EIR and will, therefore, require additional environmental review.

- **Sacramento/San Joaquin River Comprehensive Study.** USACE is currently performing a Comprehensive Study of the Sacramento and San Joaquin River watersheds to improve flood control efforts. The Delta's levees play a crucial role in controlling floods and therefore in the Comprehensive Study. The CALFED Agencies intend that final development and implementation of actions under the Comprehensive Study will be coordinated and consistent with the CALFED Bay-Delta Program.

2.2.12 Science

This ROD establishes the CALFED Science Program, which will bring world-class science to all elements of the program; ecosystem restoration, water supply reliability, water use efficiency and conservation, water quality, and flood management (e.g., levee stability). Performance measures and indicators for each program element will track progress.

The purpose of the CALFED Science Program is to provide a comprehensive framework and develop new information and scientific interpretations necessary to implement, monitor, and evaluate the success of the CALFED Program (including all program components), and to communicate to managers and the public the state of knowledge of issues critical to achieving CALFED goals.

The Science Program will be developed and directed by an interim lead scientist, who will also serve in the role of lead scientist during the initial years of program implementation. Implementation of the CALFED Science Program includes implementation of the Comprehensive

Monitoring, Assessment and Research Program (CMARP), now under the direction of the interim lead scientist. The Science Program also has primary responsibility to establish the role of adaptive management in program implementation, implement strategies to reduce uncertainties that impede successful accomplishment of CALFED goals, provide programmatic review of overall implementation of mitigation measures and integrate the CALFED Science Program with existing/related agency science programs.

An overarching principle of the Science Program is adaptive management. Adaptive management is defined as using and treating actions as partnerships between scientists and managers, designing those actions as experiments with a level of risk commensurate with the status of those species involved, and bringing science to bear in evaluating the feasibility of those experiments. New information and scientific interpretations will be developed through adaptive management, as the programs progress, and will be used to confirm or modify problem definitions, conceptual models, research, and implementation actions.

In order to better integrate scientific review into the CALFED Program, the Governor and the Secretary of the Interior will appoint an independent science board to provide oversight and peer review for the overall program. Also, specific independent science panels may be convened as standing bodies or on an as needed basis. For example, the Science Program will assist with convening an independent science panel to review implementation and operation of the EWA. In addition, the existing ERP Interim Science Board will likely become the ERP Science Panel, and provide ongoing independent review of the ERP.

While much of the need for scientific review is often focused on habitat restoration efforts, the CALFED Science Program will cover all of the program components. Water supply reliability, water use efficiency and conservation, water quality, and flood management/levee stability can each benefit from the periodic review of an independent science panel to help ensure the best investments are being made and results are being achieved, as well as form strategies to reduce scientific uncertainties. The interim lead scientist will work with CALFED program managers and CALFED Agencies to develop priorities for these program areas.

In early Stage 1, the emphasis for the CALFED Science Program will be on ecosystem restoration activities, including design of effective monitoring, targeted research and development of priorities. These efforts will be based initially on the 12 uncertainties identified in the ERP Strategic Plan.

The Science Program will not be directly involved in making regulatory decisions, but rather in ensuring that CALFED, and the CALFED Agencies, are incorporating the best available knowledge into activities and decisions that are made, as well as continuously working toward narrowing scientific uncertainties, bettering knowledge, and advancing the debate. The CALFED Science Program will be conducted in an open and collaborative manner to allow and encourage involvement of stakeholder and academic science communities. The CALFED Science Program can serve as a science clearinghouse for the CALFED Agencies and identify and articulate areas of scientific uncertainty relevant to key issues.

Actions Included in the Programmatic EIS/EIR

The CALFED Science Program will accomplish the following in Stage 1:

- Appoint an independent science board for the CALFED Program as a whole by the middle of 2001.
- Appoint an independent science panel for the EWA by the middle of 2001.
- Coordinate existing monitoring and scientific research programs.
- Refine the set of ecological, operational and other predictive models that will be used in the evaluative process by the end of 2001.
- Establish performance measures and indicators, and a consistent strategy of on-going development of these, for each of the program areas.
- Develop an annual science report, format and content, which includes:
    - Status of the species and effectiveness of efforts to improve conditions, including EWA, ERP and water management strategies, and provide recommendations to maximize fishery benefits while minimizing impacts to water supply.
    - Assessment of progress and effectiveness of each program element as indicated by performance measures and indicators.
    - Complete feasibility study to establish and construct CALFED Science Center.
    - Recommended research and/or program adjustments.
- Prepare first annual report by the end of 2001.

CALFED intends to invest approximately $300 million in the science program during Stage 1.

3. PROGRAMMATIC ENVIRONMENTAL COMPLIANCE

3.1 Clean Water Act Section 404

The CALFED Preferred Program Alternative includes numerous activities that would involve the discharge of dredged or fill material to waters of the United States (including wetlands). As such, these activities require authorization under Section 404 of the Clean Water Act before they can proceed (Section 404 permits). Activities which would require Section 404 permits range from projects involving significant construction of new infrastructure (such as new surface water storage facilities) to ecosystem restoration projects (such as creating new wetland habitat by contouring land and changing local hydrology).

The USACE issues Section 404 permits. Before the USACE can issue a Section 404 permit for a project, it must determine, among other things, whether a proposed project complies with regulations issued by EPA pursuant to Section 404(b)(1) of the Clean Water Act Section 404(b)(1) Guidelines. The USACE cannot determine whether to issue a Section 404 permit for a particular project until a project-specific administrative record is developed to permit a determination as to whether the project complies with the Guidelines as well as other relevant regulatory requirements. Because project-specific evaluations for the CALFED Program will only be completed after the ROD for the Programmatic EIS/EIR, no project-specific Section 404 permits will be issued for Program projects at the time of this ROD. However, the USACE and EPA have developed a Memorandum of Understanding (MOU) to facilitate timely consideration of Section 404 permits for CALFED projects. See Attachment 4 to this ROD.

3.2 Multi-Species Conservation Strategy Conservation Agreement, Including the Federal Endangered Species Act/California Endangered Species Act/Natural Community Conservation Planning Act Commitments

While the ERP is the Program's blueprint for restoration and recovery, the MSCS is the Program's conservation and regulatory compliance strategy. The MSCS addresses the potential adverse and beneficial effects on plant and animal species of all Program actions, including ERP actions and other Program actions such as levee system integrity, water storage and water conveyance actions. Based in large part on the ERP, the MSCS' premise is that the Program as a whole, including all program elements, will improve and increase aquatic and terrestrial habitats and improve ecological functions in the Bay-Delta. The ERP, therefore, serves two purposes: 1) to achieve Program objectives for ecosystem restoration; and 2) to enable actions from all Program elements

to be completed in compliance with FESA, CESA and NCCPA.

To serve both of these purposes, ERP implementation must be informed by the best available scientific information and by information about the implementation of other program actions. Information about the implementation of other program actions is necessary to ensure that they do not conflict with or limit the success of the ERP. In addition, ERP restoration actions must be implemented concurrently, and at commensurate levels with the other Program actions. This will ensure that the Program as a whole continues to increase aquatic and terrestrial habitats and improve ecological functions in the Bay-Delta. The MSCS-ERP Milestones identified by the USFWS, NMFS and DFG are intended to establish, based on the best information currently available, a group of actions derived from the ERP Plan that 1) establish an adequate level of ERP implementation during Stage 1, 2) for the first four years, can be implemented with annual ERP funding of $150 million, 3) would not be inhibited by proposed Stage 1 actions in other program elements, and 4) would enable proposed Stage 1 actions in other program elements to be completed in compliance with FESA, ESA and the NCCPA.

The CALFED Agencies' development of annual, near- and long-term ERP implementation priorities and strategies will be based on the goals and objectives of the ERP Strategic Plan, the MSCS, FESA recovery plans, and implementation plans developed for specific ecological management zones, and will be informed by the Science Program. The MSCS-ERP Milestones represent the USFWS', NMFS' and DFG's objectives for ERP implementation that would allow Covered Species to make significant progress toward restoration and recovery. As with ERP implementation priorities and strategies generally, USFWS, NMFS, and DFG intend that the Science Program will inform the MSCS-ERP Milestones. Specifically, USFWS, NMFS, and DFG will seek annual review within the Science Program of 1)whether other program elements conflict with ERP implementation priorities and strategies so as to limit the success of the ERP, and 2) whether the ERP implementation priorities and strategies will ensure that the Program as a whole continues to increase aquatic and terrestrial habitats and improve ecological functions in the Bay-Delta. As the Science Program develops information about ERP implementation, USFWS, NMFS, and DFG will revise the MSCS-ERP Milestones as necessary, consistent with the FESA and NCCPA.

USFWS, NMFS and DFG will not approve revisions to the MSCS-ERP Milestones that would cause or allow an effect to Covered Species or critical habitat designated under FESA that was not considered in the programmatic regulatory determinations, or would otherwise require the re-initiation of formal consultation under 50 CFR section 402.16. Consequently, the USFWS and NMFS expect that their approved revisions to the MSCS-ERP Milestones can be incorporated in each agency's programmatic biological opinions through informal consultation, rather than formal consultation, under section 7 of FESA. DFG will incorporate its approved revisions to the MSCS-ERP Milestones by amending the "California Department of Fish and Game Approval and Supporting Findings for the CALFED Bay-Delta Program Multiple Species Conservation Strategy."

3.3 Programmatic Endangered Species Act Section 7 Biological Opinions

Federal agencies must achieve FESA compliance under Section 7 of the act. Section 7 states that any Federal agency that funds, authorizes, or carries out an action that may affect a listed species must consult with USFWS and/or NMFS. This programmatic consultation is to ensure that the action is not likely to jeopardize the continued existence of any endangered or threatened species, or to result in the destruction or adverse modification of habitat critical to such species. If the lead agency determines that an agency action is likely to affect a listed species or critical habitat, the agency taking the action must initiate formal consultation. This programmatic consultation does not authorize any incidental take for listed or proposed species.

Formal consultation begins when the Federal agency provides USFWS or NMFS a written biological assessment of the action. USFWS and/or NMFS review the biological assessment and other relevant information, then do the following:

- Determine the sufficiency of information for consultation.
- Provide a written biological opinion that details how the action will affect any endangered species, threatened species, or critical habitat.
- Develop reasonable and prudent alternatives to the action that will avoid jeopardizing the continued existence of such species.
- Develop reasonable and prudent measures to the action to minimize the effects of the incidental taking.

Reasonable and prudent alternatives and reasonable and prudent measures are non-discretionary in order to be exempt from the prohibitions of take under section 9 of the Act. If the action will cause incidental take of an endangered or threatened species, USFWS and/or NMFS will provide a statement of the level of take that is anticipated to occur from implementing the action. If the Federal agency or other entity carrying out the action implements the specified measures and does not exceed the level of take stated in the biological opinion, FESA does not prohibit the incidental take caused by the action.

The MSCS served as the biological assessment for CALFED and initiated a programmatic consultation under Section 7. USFWS and NMFS have prepared programmatic biological opinions for CALFED based on the MSCS and other relevant information. See Attachment 6 to this ROD. As CALFED actions or groups of actions requiring Section 7 consultations are identified and defined, Action Specific Implementation Plans (ASIPs) can be prepared that use information and analyses in the MSCS and the programmatic biological opinions. The ASIPs will serve as the biological assessment of the CALFED actions or groups of actions; they will provide necessary details about the actions and their impacts on MSCS evaluated species and NCCP communities. USFWS and NMFS will then use the ASIPs to develop action-specific biological opinions.

CALFED Program implementation, in conjunction with the MSCS and programmatic biological opinions, will provide benefits in subsequent project-specific consultations. Specifically, individual projects that qualify for consultation will be evaluated within the context of the Program as a whole, which includes major elements designed to improve the environmental baseline and lead to the recovery of targeted species. These major elements will be subject to on-going monitoring, evaluation, and the application of adaptive management. Project-specific biological opinions will take into account the environmental benefits that accrue from the CALFED Program. As a result, FWS and NMFS anticipate that implementation of the overall CALFED Program will streamline the ESA compliance process and, as actions are taken that benefit listed species, will reduce the need for additional provisions to satisfy legal requirements.

3.4 Natural Community Conservation Plan Determination

The NCCPA authorizes the preparation of Natural Community Conservation Plans (NCCPs). NCCPs provide the means for regional or areawide protection and perpetuation of natural wildlife diversity, while allowing compatible and appropriate development and growth. Federal, State, and local agencies may undertake natural community conservation planning independently or in cooperation with other persons. NCCPs must be approved by the DFG. DFG may authorize incidental take of identified species, including endangered and threatened species, whose conservation and management is provided for in an approved NCCP. Because NCCPA allows DFG to authorize incidental take of endangered and threatened species, an NCCP may be used to comply with CESA.

The MSCS has been submitted to DFG as a proposed programmatic NCCP. Based on the MSCS and other relevant information, DFG will determine whether the MSCS complies with NCCPA. If the MSCS complies with NCCPA, DFG will prepare an NCCP approval and issue supporting findings. As under FESA, when specific CALFED actions or groups of actions have been identified and defined, ASIPs that use information and analyses in the MSCS and the programmatic NCCP approval will provide necessary details about the actions and their impacts on MSCS evaluated species and NCCP communities. The ASIPs can then serve as project-specific NCCPs for CALFED actions or groups of actions. See Attachment 7 to this ROD.

3.5 Clean Water Act Section 401 Memorandum of Understanding

Under Section 401 of the CWA, the SWRCB and the RWQCBs certify whether or not federally licensed or funded projects are consistent with the maintenance or attainment of water quality requirements. The SWRCB and the RWQCBs for the San Francisco Bay and Central Valley Regions have signed a memorandum of understanding as to how they will process the Section 401 certification of the CALFED storage projects and other projects requiring such certification. See

Attachment 8 to this ROD.

3.6 Coastal Zone Management Act Programmatic Consistency Determination

Under the Coastal Zone Management Act (CZMA) of 1972, coastal states are required to develop Coastal Zone Management Programs, and Federal agencies are required to certify that any proposed activities in or affecting the coastal zone are consistent with the State's program. In California, the San Francisco Bay Conservation and Development Commission (BCDC) oversees the San Francisco Bay segment of California's Coastal Zone Management Program. Among other areas, BCDC also has permit jurisdiction over projects in certain waterways up to the Sacramento-San Joaquin Delta (east of Chipps Island) that empty into the Bay and in specific saltponds and managed wetlands.

The Program has prepared a Programmatic Coastal Zone Management Act Consistency Determination that documents the possible effects of the Preferred Program Alternative on coastal resources. See Attachment 9 to this ROD. The consistency determination documents the actions that the Program will take to ensure that the Preferred Program Alternative is carried out in a manner consistent, to the maximum extent practicable, with the CZMA and the California Coastal Act of 1976. BCDC has approved the consistency determination.

3.7 Permit Clearinghouse

The CALFED Agencies will establish a permit clearinghouse process to coordinate and expedite permit applications across all CALFED programs. This process will detailed in an MOU by December 2000. As part of the clearinghouse, the CALFED Agencies will provide:

- A permit handbook
- Permit tracking database that tracks milestones for CALFED actions
- A unified application format
- A non-binding dispute resolution process
- Annual reports and meetings to track progress
- Permit coordinators

The CALFED Agencies, working in regulatory and/or implementation roles, will do the following as part of the permit clearinghouse process:

- Participate in regular meetings and assist in preparation of annual reports to track progress on overall CALFED program implementation.
- Identify and pursue regional environmental permits, opportunities to group permits, a single

environmental review process for multiple projects, or other measures that increase the efficiency of environmental compliance efforts.

- Appoint a single point of contact for their agency and as appropriate, a single point of contact for regulatory compliance activities.
- Form multi-agency, multi-disciplinary teams to assist in project definition, impact analysis, identification of avoidance and mitigation measures, development of permit conditions and information necessary to comply with regulatory requirements.
- Develop standard guidance, study methodologies, and mitigation requirements as needed.
- Respond in a timely manner to environmental documents, permit applications, other regulatory requirements.
- Ensure that environmental considerations are an integral part of project formulation.
- Identify issues in dispute early, attempt to resolve those issues at the lowest level possible, and elevate those issues as needed in an orderly manner so that they can be resolved and not result in delays.

The permit clearinghouse concept does not provide CALFED projects with any higher priority than other projects submitted by non-CALFED Agencies. The CALFED Agencies will support increases in regulatory staff to assure all CALFED and non-CALFED projects submitted for permitting have equal priority and that the CALFED Program schedule will be met. In addition, the permit clearinghouse does not change the standard of review under statutes governing the review of each regulatory agency.

Having considered the contents of this document, its attachments and the documents supporting this decision, we hereby adopt this Record of Decision. By signing this Record of Decision together, we exercise our respective authorities over only those portions relevant to our authority.

APPENDIX A

Mitigation Measures Adopted in the Record of Decision

Appendix A
Mitigation Measures Adopted in the Record of Decision

The CALFED Agencies commit to considering and adopting the following mitigation measures where appropriate in development and implementation of project specific actions. The mitigation measures address short-term, long-term and cumulative effects of the CALFED Program. The measures are grouped by section from the impact analysis chapters of the Final Programmatic EIS/EIR.

5.1 Water Supply and Water Management. Potentially significant effects of implementing the Preferred Program on water supply and water management include temporary local water supply interruptions due to turbidity of water during construction of Program facilities, levee construction and maintenance, and habitat restoration activities.

The following mitigation measures will reduce potential effects of implementation of the Preferred Program Alternative on water supply and water management:

1. Use best construction and drainage management practices to avoid transport of soils and sediments into waterways.
2. Use cofferdams to construct levees and channel modifications in isolation from existing waterways.
3. Use sediment curtains to contain turbidity plumes during dredging.
4. Schedule ground disturbing construction during the dry season.

5.3 Water Quality. Implementation of the Preferred Program Alternative may have several potentially significant effects on water quality. These effects include: (1) Releases of inorganic and organic suspended solids into the water column and turbidity resulting from increased erosion during construction, dredging, or drainage of flooded lands; (2) Releases of toxic substances, such as pesticides, selenium, and heavy metal residues, into the water column during construction and dredging and other Program actions; (3) Net increases in salinity if evaporation increases converting irrigated cropland to wetlands; (4) Increased electrical conductivity (a measure of salinity) of water in the Delta; (5) Increases of TOC in river water caused by the increased contact between flowing or ponded water and vegetation or peat soils that would result from conversion of agricultural lands to wetlands and from actions in other Program elements; (6) Increased water temperatures and resultant decreased dissolved oxygen concentrations due to the increased residence time of water in the Delta and from actions in various Program elements; (7) Decreases in in-stream water quality if water use efficiency measures or water transfers reduce diluting flows; (8) Increases in concentrations of constituents of concern if water transfers reduce in-stream flows and deplete river assimilative capacity; (9) Increase in methylation of mercury in constructed shallow-water habitat; (10) Degradation of surface water by the transfer of poorer quality groundwater; (11) Changes in natural flow regimes in areas where new surface storage is built; and (12) Surface storage innundation of toxic material.

The following mitigation measures will reduce potential effects of implementation of the Preferred

Program Alternative on water quality:

1. Improve treatment levels provided at municipal wastewater treatment plants to upgrade the quality of the constituents of concern discharged to receiving waters in order to compensate for the reduction in dilution caused by improved water use efficiency. Improved salt management of wastewater inputs to treatment plants could reduce salt concentrations in discharges.
2. Release additional water from enlarged or additional off-stream surface storage, or from additional groundwater storage.
3. Release additional water from storage in existing reservoirs or groundwater basins.
4. Treat wastewater at the source, such as Delta drains, upgrade water treatment processes at drinking water treatment plants and/or provide treatment at the point of use (consumer's tap).
5. Use innovative, cost-effective disinfection processes (for example, UV irradiation, and ozonation, in combination with other agents) that form fewer or less harmful DBPs.
6. Use existing river channels for water transfers and timing the transfers to avoid adverse water quality effects.
7. Use best construction and drainage management practices to avoid transport of soils and sediments into waterways.
8. Use cofferdams to construct levees and channel modifications in isolation from existing waterways.
9. Use sediment curtains to contain turbidity plumes during dredging.
10. Separate water supply intakes from discharges of agricultural and urban runoff.
11. Apply agricultural and urban BMPs, and treat drainage from lands with concentrations of potentially harmful constituents to reduce contaminants. Treat drainage from agricultural lands underlain by peat soils to remove TOC.
12. Relocate diversion intakes to locations with better source water quality.
13. Restore additional riparian vegetation to increase shading of channels and reduce evaporation.
14. Identify and investigate issues regarding beneficial reuse of dredged material, including conducting core sampling and analysis of proposed dredged areas, and implement engineering solutions to avoid or prevent environmental exposure to toxic substances after dredging.
15. Cap exposed toxic sediments with clean clay/silt and protective gravel.
16. Test for mercury in soils and locate constructed shallow-water habitat away from sources of mercury until methods for reducing mercury in water and sediments are implemented.
17. Operate storage facility operations to maintain the frequency, magnitude, and duration of flows necessary to maintain and restore downstream water quality and habitat.
18. Avoid innundation or design solutions to innundation of toxic materials, such as covering with an engineered cap.
19. Schedule ground disturbing construction during the dry season.
20. Follow established and proper procedures and regulations for identifying, removing and disposing of contaminated materials.
21. Utilize the criteria in the Water Transfer Program, in conjunction with existing legal constraints on water transfers, to protect against adverse effects due to water transfers.

The criteria for future water transfer proposals include:

- Water rights of all legal water users must not be impaired.
- Transfers must not harm fish and wildlife resources and their habitats.
- Transfers must not cause overdraft or degradation of groundwater basins, or impair correlative rights of overlying users.

22. Develop new groundwater basin management plans or expand existing groundwater basin management plans, including defining objectives, project boundaries, responsibilities, operation and maintenance specifications and procedures, and conditions under which corrective actions are taken.
23. Reduce or discontinue groundwater pumping.
24. Monitor and test groundwater wells and aquifers.
25. Continue the studies concerning reuse of beneficial Bay dredge material in the Delta for potential water quality impacts related to salinity, metals mobilization, and other environmental and health hazards.
26. Investigate all potential sources of borrow and the cost effectiveness of each source's use for levee rehabilitation and construction, including the use of sediment traps as a source of borrow.
27. Prepare a borrow plan that includes future costs and options for obtaining adequate quantities of borrow needed for implementation of the Levee System Integrity Plan.
28. Modify water conveyance operations, including DCC and south Delta operations. Program implementation will occur in phases to permit new information gained from studies and monitoring to influence changes in facility design and operations.

5.4 Groundwater. Implementation of the Preferred Program Alternative may have potentially significant effects on groundwater. These effects include: (1) Changes in groundwater levels; (2) Increased demand for groundwater supplies; (3) Increased groundwater overdraft; (4) Increased land subsidence; (5) Increased degradation of groundwater quality from contaminant movement, salt-water intrusion, or naturally poor-quality water drawn into the aquifer; and (6) Impacts from groundwater recharge and storage system operations.

The following mitigation measures will reduce potential effects of implementation of the Preferred Program Alternative on groundwater:

1. Create additional groundwater or surface water storage facilities to improve water supply reliability and decrease overdraft.
2. Support voluntary transfers of water from basins with excess supplies.
3. Purchase water rights from willing sellers (including transferring water rights between sectors—for example, from agricultural to municipal uses).
4. Support local groundwater management that reduces overdraft and third-party effects, including reduction or discontinuation of groundwater pumping.
5. Implement conservation measures to reduce demand.
6. Integrate the Ecosystem Restoration Program floodplain restoration efforts with setback levees.
7. Support local and regional efforts to increase water supplies from recycling.

8. Support increased regulations regarding new and existing domestic wells and septic systems.
9. Develop alternative water supplies.
10. Monitor and test groundwater wells and aquifers.
11. Limit new septic tank systems in vulnerable areas.
12. Allow water levels to increase periodically.
13. Import new soil (including dredged spoil) to raise land surface.
14. Support local projects to recharge aquifers.
15. Support local agencies in distributing groundwater pumping over a wide region rather than to a concentrated area to minimize drawdown of the aquifer.
16. Treat extracted groundwater at the well head.
17. Dilute poor-quality groundwater with higher quality water.
18. Support local agencies in developing new groundwater basin management plans or expanding existing groundwater basin management plans, including defining objectives, project boundaries, responsibilities, operation and maintenance specifications and procedures, and conditions under which corrective actions are taken.
19. Temporarily remove the recharge system from service to avoid effects associated with high water tables.
20. Monitor water-level conditions on islands adjacent to flooded Delta islands.
21. Install interception wells at in-Delta storage facilities to control seepage.
22. Line conveyance canals to prevent seepage.
23. Control seepage through pumping and other appropriate measures.
24. Design new levees and improve existing levees to withstand hydraulic stresses and seepage from flooding Delta islands.
25. Utilize the criteria and objectives in the Water Transfer Program, in conjunction with existing legal constraints on water transfers, to protect against adverse effects due to water transfers. The criteria for future water transfer proposals include:
    - Water rights of all legal water users must not be impaired.
    - Transfers must not cause overdraft or degradation of groundwater basins, or impair correlative rights of overlying users.

5.5 Geology and Soils. Implementation of the Preferred Program Alternative may have potentially significant effects on geology and soils. These effects may include: (1) Conversion of agricultural land soils for levee system construction and potential for erosion on outboard slope of levees; (2) Increases in local subsidence from potential increased reliance on groundwater use; (3) Increases in wind and soil erosion and in soil salinity due to fallowed agricultural lands; (4) Increased construction-related short-term soil erosion, and increased sediment deposition and soil compaction; (5) Potential changes in downstream geomorphology from enlarging existing storage facilities and other Program actions; and (6) Ground disturbance, inundation, seepage, and shoreline wind- and wave-generated erosion from new storage facilities and other Program actions.

The following mitigation measures will reduce potential effects of implementation of the Preferred

Program Alternative on geology and soils:

1. Monitor groundwater levels and subsidence in areas of increased reliance on groundwater resources and regulate withdrawal rates at levels below those that cause subsidence.
2. Minimize and avoid direct groundwater transfers or groundwater substitution transfers from regions: 1) experiencing long-term overdraft, 2) where subsidence historically has occurred, or 3) where local extensometers indicate that subsidence rates are increasing.
3. Protect flooded Delta island inboard levee slopes against wind and wave erosion with vegetation, soil matting, or rock.
4. Protect exposed soils with mulches, geotextiles, and vegetative ground covers during and after project construction activities in order to minimize soil loss.
5. Implement erosion control measures and bank stabilization projects.
6. Increase sediment deposition and provide substrate for new habitat by planting terrestrial and aquatic vegetation.
7. Measure channel morphology over time to monitor changes and implement erosion control measures where needed.
8. Re-use dredged materials to reduce or replace soil loss.
9. Leave crop stubble from previous growing season in place while fallowing and employ cultivation methods that will cause the least amount of disturbance in order to minimize erosion of surface soils.
10. Limit the salinity of replacement water, relative to local conditions, in water transfers.
11. Ensure that the volume of irrigation water used is sufficient to flush accumulated salts from the root zone.
12. Operate new storage facilities to minimize sediment trapping and increase sediment transport in rivers and tributaries.
13. Retrofit soil-comprised structures to seismic events with shock-absorbing devices and materials in areas of seismic vulnerability, wherever possible.
14. Prepare and implement best construction management plans.
15. Prepare and implement a water quality and soils monitoring program.
16. Prepare and implement construction mitigation plans.
17. Prepare and implement contingency plans for wetland and marshland restoration.
18. Modify storage facility operations to maintain the frequency, magnitude, and duration of flows necessary to maintain and restore downstream habitat.
19. Control boat traffic in order to reduce boat wakes to levels that will not cause levee or bank erosion.
20. Monitor water-level conditions on islands adjacent to in-Delta storage.
21. Install interception wells at in-Delta storage facilities to control seepage.
22. Line conveyance canals to prevent seepage.
23. Control seepage through pumping and other appropriate measures.
24. Design new levees and improve existing levees to withstand hydraulic stresses and seepage from flooding Delta islands.
25. Use cofferdams to construct levees and channel modifications in isolation from existing waterways.
26. Use sediment curtains to contain turbidity plumes during dredging.
27. Investigate the cost effectiveness and safety of using sediment traps as a source of borrow.

5.6 Noise. Implementation of the Preferred Program Alternative may have potentially significant effects on noise. These effects may include: (1) Increased noise from heavy equipment operation during construction; (2) Noise from construction-related traffic along major access and haul routes and construction labor force vehicle traffic; (3) Increased noise from facility operation of spillways, pumping generating plants, and switchyards; (4) Increased noise from automobile or boat traffic associated with recreational use at enlarged reservoirs; and (5) Increased traffic noise from permanently relocated roadways.

The following mitigation measures will reduce potential effects of implementation of the Preferred Program Alternative on noise:

1. Use electrically powered equipment instead of internal combustion equipment where feasible.
2. Locate staging and stockpile areas, and supply and construction vehicle routes as far away from sensitive receptors as possible.
3. Establish and enforce construction site and haul road speed limits.
4. Restrict the use of bells, whistles, alarms, and horns to safety warning purposes.
5. Design equipment to conform with local noise standards.
6. Locate equipment as far from sensitive receptors as possible.
7. Equip all construction vehicles and equipment with appropriate mufflers and air inlet silencers.
8. Restrict hours of construction to periods permitted by local ordinances.
9. Locate noisy equipment within suitable sound-absorbing enclosures.
10. Erect sound wall barriers or noise attenuation berms between noise generation sources and sensitive receptors.
11. Schedule construction activities to avoid breeding seasons of sensitive species and peak recreating use.
12. Locate redirected roadways away from sensitive receptors.
13. Encourage use of public transportation and carpooling for construction workers.
14. Restrict boating speeds or access to areas with sensitive receptors.
15. Conduct project-specific noise analyses for actions with noise impacts.

5.7 Transportation. Implementation of the Preferred Program Alternative may have potentially significant effects transportation. These effects may include: (1) Increasing local traffic flows as the public accesses recreational resources at new storage facilities; (2) Changing traffic flows as roads are temporarily rerouted around construction sites; (3) Relocating or permanently closing roads; (4) Delays and disruptions resulting from detouring traffic as new roadways and railroad bridges are constructed around storage and conveyance facilities; (5) Adding construction vehicles to existing traffic levels, especially on narrow, two-lane local roads with winding routes; (6) Closing two-lane roads to one lane in order to facilitate roadway improvements or relocations associated with the Watershed Program; (7) Impeding or blocking patrol or rescue boats in Delta channels where fish barriers and flow control structures are installed; and (8) Creating safety conflicts by operating large, slow-moving dredging equipment on Delta waterways.

The following mitigation measures will reduce potential effects of implementation of the Preferred Program Alternative on transportation:

1. Provide convenient and parallel detours to routes closed during construction.
2. Allow trains to use existing tracks while bridges are being built.
3. Encourage use of public transportation and carpooling for construction workers.
4. Clearly mark roadway intersections with warnings where visibility is poor in the project vicinity.
5. Provide boat portage or a stationary jib crane.
6. Relocate boat launch facilities.
7. Relocate emergency access roads.
8. Require contractors to follow appropriate state and federal safety protocols.
9. Coordinate dredging and safety precautions with state and local authorities.
10. Schedule construction at times and seasons to minimize delays.
11. Expand public transportation resources and local roadways.
12. Expand public transportation, roads, and highways.
13. Locate roadways in areas with fewer conflicts.
14. Design roadways to avoid or minimize traffic congestion.

5.8 Air Quality. Implementation of the Preferred Program Alternative may have potentially significant effects on air quality. These effects may include: (1) Direct, short-term air pollutant emissions during construction activities; (2) Fugitive emissions of wind-blown dust; (3) Emissions associated with prescribed burning programs; (4) Emissions from increases in equipment use and cultivation, agricultural chemical use, and crop shifting and burning; (5) Emissions if land use changes lead to higher recreational uses; and (6) Emissions from use of fossil fuels or other energy resources associated with pressurized irrigation systems; and (7) Indirect air quality impacts from increased power generation to meet Program energy consumption and changes in operation.

The following mitigation measures will reduce potential effects of implementation of the Preferred Program Alternative on air quality:

1. Set traffic limits on construction vehicles.
2. Maintain properly tuned equipment.
3. Limit the hours of operation or amount of equipment.
4. Limit the use of agricultural chemicals.
5. Coordinate prescribed burning programs with relevant air quality management agencies to ensure that the programs are accounted for in air quality management plans.
6. Regularly water construction sites to control levels of dust in the air.
7. Use soil stabilizers and dust suppressants on unpaved service roadways.
8. Conduct daily contained sweeping of paved surfaces.
9. Limit vehicle idling time.
10. Use alternatively fueled equipment.
11. Require selection of borrow sites that are closest to fill locations.
12. Implement construction practices that reduce generation of particulate matter.

13. Hydoseed and mulch exposed areas.
14. Use cultivation practices that minimize soil disturbance.
15. Follow air basin management plans to avoid or minimize vehicle-related emissions.
16. Restrict the kinds of recreational vehicles or the times of operation for certain off-road vehicles on fallowed agricultural land to limit the amount of fugitive dust.
17. Implement prescribed burning during favorable weather conditions.
18. Implement alternatives to crop burning including tilling and shallow flooding.
19. Coordinate crop stubble burning with relevant air quality management agencies to ensure that the programs are accounted for in air quality management plans.
20. Encourage use of public transportation and carpooling for construction workers.
21. Obtain replacement power from non-emitting sources such as other hydro, solar, and wind sources. This can occur through construction of, or the use of incentives to construct non-emitting power plants. This approach is consistent with state and federal policies related to promoting use of renewable resource type generation as expressed in Public Utility Code Section 381(c) (part of what is commonly referred to as AB 1890) and Executive Order 12902.
22. Utilize the best available control technology for new power production facilities.

6.1 Fisheries and Aquatic Systems. Implementation of the Preferred Program Alternative may have potentially significant effects on fisheries and aquatic systems. These effects may include: (1) Increased non-native species abundance and distribution to levels detrimental to native species from reestablishment of aquatic areas; (2) Blocked access to habitat and altered water quality and flow conditions from placement of barriers in the south Delta; (3) Altered natural ecosystem structure, removal of benthic communities, and creation of conditions that may damage habitat for desired species from dredging activities and other Program actions; (4) Release of toxic substances into surface waters; (5) Short-term disturbance of existing biological communities and species habitat, mobilized sediments, and input contaminants from construction activities; (6) Reduced streamflow and Delta outflow, changed seasonal flow and water temperature variability from water supply management, and changes in salinity associated with several Program elements resulting in reduced habitat abundance, impaired species movement, and increased loss of fish to diversions; (7) Increased entrainment loss of chinook salmon and other species from diversions to new off-stream and in-Delta storage; (8) Reduced frequency and magnitude of net natural flow conditions in the south and central Delta from Delta Cross Channel operations and south Delta barriers resulting in reduced system productivity, impaired species movement, and increased losses to diversions; (9) Reduced net flow conditions in the Sacramento River downstream of the diversion facility on the Sacramento River; (10) Increased fish mortality through abrasion, increased predation, and other factors from the new fish screen facility for the diversion facility on the Sacramento River; and (11) Delayed migration and reduced spawning success for adult fish moving from the Mokelumne River channels into the Sacramento River from fish screens and a diversion facility on the Sacramento River.

The following mitigation measures will reduce potential effects of implementation of the Preferred Program Alternative on fisheries and aquatic systems:

1. Implement BMPs, including a storm water pollution prevention plan, toxic materials control and spill response plan, and vegetation protection plan.
2. Limit construction activities to windows of minimal species vulnerability.
3. Create additional habitat for desired species, including increased aquatic area and structural diversity through construction of setback levees and channel islands.
4. Control undesirable non-native species.
5. Operate new and existing diversions to avoid and minimize effects on fish--avoid facility operations during periods of high species vulnerability.
6. Locate the diversion points to avoid primary distribution of desired species.
7. Control predators in the diversion facility (screen bays) and modify diversion facility structure and operations to minimize predator habitat.
8. Construct a barrier to fish movement on Georgiana Slough.
9. Coordinate and maximize water supply system operations flexibility consistent with seasonal flow and water temperature needs of desired species.
10. Identify and investigate issues regarding beneficial reuse of dredged material, including conducting core sampling and analysis of proposed dredged areas, and implement engineering solutions to avoid or prevent environmental exposure to toxic substances after dredging.
11. Cap exposed toxic sediments with clean clay/silt and protective gravel.
12. Locate constructed shallow-water habitat away from sources of mercury until methods for reducing mercury in water and sediment are implemented.
13. Use cofferdams to construct levees and channel modifications in isolation from existing waterways.
13. Use sediment curtains to contain turbidity plumes during dredging.
14. Schedule ground disturbing construction during the dry season.
15. Follow established and proper procedures and regulations for identifying, removing and disposing of contaminated materials.
16. Utilize the criteria and objectives in the Water Transfer Program, in conjunction with existing legal constraints on water transfers, to protect against adverse effects due to water transfers. The criteria for future water transfer proposals include:
    - Transfers must not harm fish and wildlife resources and their habitats.

6.2 Vegetation and Wildlife. Implementation of the Preferred Program Alternative may have potentially significant effects on vegetation and wildlife. These effects may include: (1) Temporary and permanent loss and degradation of wetland, riparian and other natural communities; (2) Substantial temporary or permanent loss and disturbance of wintering waterfowl foraging habitat; (3) Substantial decrease in important upland wildlife habitat and use areas; (4) Temporary and permanent fragmentation of riparian habitats and/or wildlife movement corridors; (5) Temporary or permanent loss of habitat or direct impacts on special-status species; (6) Loss of portions of rare natural communities and significant natural areas; (7) Temporary disturbance or mortality of special-status species due to construction and habitat management activities; (8) Permanent loss of incidental wetland and riparian habitats that depend on agricultural inefficiencies; and (9) Reduction in quantity or quality of forage for species of concern.

The following mitigation measures will reduce potential effects of implementation of the Preferred Program Alternative on vegetation and wildlife:

1. Avoid direct or indirect disturbance to wetland and riparian communities, special-status species habitat, rare natural communities, significant natural areas, and other sensitive habitat.
2. Restore and enhance sufficient in-kind wetland and riparian habitat or rare natural communities and significant natural areas at offsite locations (near project sites) before or at the time that project impacts are incurred. Replace not only acreage lost, but also habitat value loss.
3. Design Program features to permit on-site mitigation or nearby restoration of wetland, riparian habitat, special-status species habitat, rare natural communities, and significant natural areas that have been removed by permanent facilities.
4. Phase the implementation of Ecosystem Restoration Program habitat restoration to offset temporary habitat losses and to restore habitat (including special-status species habitat) before, or at the same time that, project impacts associated with the Ecosystem Restoration Program are incurred.
5. Restore wetland and riparian communities, special-status species habitat, and wildlife use areas temporarily disturbed by on-site construction activities immediately following construction. Example actions include direct planting of native plants, controlling non-native plants to improve conditions for reestablishing native plants, and enhancing and restoring the original site hydrology to allow for the natural reestablishment of the affected plant community.
6. Avoid creating wetlands in areas with high concentrations of mercury in sediments and anaerobic conditions.
7. Phase the implementation of modifications to levees that would be necessary to meet PL 84-99 standards in order to minimize the effects of fragmentation of riparian habitats and associated wildlife.
8. Implement BMPs such as avoiding disturbance to highly erodible soils and installing siltation barriers and detention basins to reduce the potential for siltation of nearby wetlands.
9. Maintain sufficient outflow downstream of constructed off-stream reservoirs to maintain existing downstream wetland riparian communities.
10. Restore or enhance sufficient waterfowl foraging habitat near existing use areas to offset impacts on the abundance, quality and availability of waterfowl forage. Restoration and enhancement actions include restoring and managing seasonal wetlands for wintering waterfowl, producing crops with high forage value (such as corn and rice), and modifying farming practices to increase forage availability (for example, leaving portions of forage crops unharvested through winter or shallowly flooding fields).
11. Avoid important wildlife habitat areas, such as critical deer winter range and fawning habitat.
12. Restore and enhance important wildlife habitat use areas temporarily disturbed by on-site construction activities by planting and maintaining native species immediately following construction.
13. Restore and enhance upland habitat areas within affected watersheds or in other watershed

if sufficient habitat enhancement is unavailable within the affected watershed. This could include modifying existing land management practices (for example, grazing and fire management practices) to improve conditions for the natural reestablishment and long-term maintenance of affected plant communities and habitats.

14. Avoid direct or indirect disturbance to areas occupied by special-status species.
15. Avoid construction or maintenance activities within or near occupied special-status species habitat areas or important wildlife use areas when species may be sensitive to disturbance, such as during the breeding season.
16. Restore habitat areas occupied by special-status species that are temporarily disturbed by on-site construction activities immediately following construction.
17. Restore and enhance suitable habitat areas that are occupied by, or are near and accessible to, special status species that have been affected by the permanent removal of occupied habitat areas.
18. Phase habitat restoration actions to restore sufficient suitable habitat to minimize the adverse affects of impacts on occupied special-status species habitats before impacts are incurred.
19. For species for which relocation or artificial propagation is feasible, establish additional populations of special-status species adversely affected by the Program in suitable habitat areas elsewhere within their historical range.
20. Provide incentives to alter agricultural practices to improve habitat conditions for affected special-status species that use agricultural lands. This could included planting and managing crops to increase the availability or quantity of forage for affected species.
21. Avoid direct or indirect disturbances to rare natural communities and significant natural areas.
22. Restore or enhance disturbed rare natural communities or significant natural areas at off-site locations before, or when, Program actions that could affect these communities are incurred.
23. Restore rare natural communities or significant natural areas at or near affected locations after Program activities are completed.
24. Manage recreation-related activities on lands managed under the Program to minimize or avoid potential adverse effects of recreation-related activities on sensitive habitats, important wildlife use areas, and special-status species.
25. Phase ERP to initially restore natural waterfowl foraging on agricultural lands with low forage value while restored habitat with high forage value develops.
26. Phase ERP to initially restore wetland habitat with high forage value to offset the loss of agricultural foraging habitat that may result from the ERP.
27. Restore riparian vegetation disturbed by on-site construction activities immediately following construction.
28. Restore or enhance sufficient in-kind riparian habitat at off-site locations, near project sites, in a manner that reduces the degree of existing habitat fragmentation before, or when, project impacts are incurred to offset habitat losses.
29. Restore habitat temporarily disturbed by on-site construction activities immediately following construction.
30. Restore rare natural communities, significant natural areas, and wildlife use areas

temporarily disturbed by on-site construction activities immediately following construction. Example actions include direct planting of native plants, controlling non-native plants to improve conditions for reestablishing native plants, and enhancing and restoring the original site hydrology to allow for the natural reestablishment of the affected plant community.

31. Restore and enhance suitable habitat areas that are occupied by, or are near and accessible to, special-status species that have been adversely affected by the permanent removal of occupied habitat areas.

7.1 Agricultural Land and Water Use. Implementation of the Preferred Program Alternative may have potentially significant effects on agricultural land and water use. These effects may include: (1) Conversion of prime, statewide important, and unique farmlands to project uses; (2) Conflicts with local government plans and policies; and (3) Conflicts with adjacent land uses.

The following mitigation measures will reduce potential effects of implementation of the Preferred Program Alternative on agricultural land and water use:

1. Site and align Program features to avoid or minimize effects on agriculture.
2. Examine structural and nonstructural alternatives to achieve project goals in order to avoid effects on agricultural land.
3. Implement features that are consistent with local and regional land use plans.
4. Involve all affected parties, especially landowners and local communities, in developing appropriate configurations to achieve the optimal balance between resource effects and benefits.
5. Retain water allocations from retired drainage-impaired lands within the existing water districts.
6. Support the testing and application of alternative crops to idled farmland (for example, agroforestry or energy crops).
7. Provide water supply reliability benefits to agricultural water users.
8. Support the California Farmland Conservancy Program in acquiring easements on agricultural land in order to prevent its conversion to urbanized uses and increase farm viability. Focus on lands in proximity to where any conversion effect takes place.
9. Restore existing degraded habitat as a priority before converting agricultural land.
10. Focus habitat restoration efforts on developing new habitat on public lands before converting agricultural land.
11. If public lands are not available for restoration efforts, focus restoration efforts on acquiring lands that can meet ecosystem restoration goals from willing sellers where at least part of the reason to sell is an economic hardship (for example, lands that flood frequently or where levees are too expensive to maintain).
12. Use farmer-initiated and developed restoration and conservation projects as a means of reaching Program goals.
13. Where small parcels of land need to be acquired for waterside habitat, seek out points of land on islands where the ratio of levee miles to acres farmed is high.
14. Obtain easements on existing agricultural land for minor changes in agricultural practices

(such as flooding rice fields after harvest) that would increase the value of the agricultural crop(s) to wildlife.

15. Include provisions in floodplain restoration efforts for compatible agricultural practices.
16. Purchase water for habitat purposes so that the same locality is not affected over the long term.
17. Use a planned or phased habitat development approach in concert with adaptive management.
18. Minimize the amount of water supply required to sustain habitat restoration acreage.
19. Develop buffers and other tangible support for remaining agricultural lands. Vegetation planted on these buffers should be compatible with farming and habitat objectives.
20. In implementing levee reconstruction measures, work with landowners to establish levee reconstruction methods that avoid or minimize the use of agricultural land.
21. Work with landowners to establish levee subsidence BMPs that avoid effects on land use practices. Through adaptive management, further modify BMPs to reduce effects on agricultural land.
22. Implement erosion control measures to the extent possible during and after project construction activities. These erosion control measures can include grading the site to avoid acceleration and concentration of overland flows, using silt fences or hay bales to trap sediment, and revegetation areas with native riparian plants and wet meadow grasses.
23. Protect exposed soils with mulches, geotextiles, and vegetative ground covers to the extent possible during and after project construction activities in order to minimize soil loss.
24. Use rotational fallowing to reduce selenium drainage.
25. When it appears that land within an agricultural preserve may be acquired from a willing seller by a State CALFED agency for a public improvement as used in Government Code Section 51920, advise the Director of Conservation and the local governing body responsible for the administration of the preserve of the proposal.
26. Limit the number of acres that can be fallowed (in order to produce transferrable water) in a given area (district or county) or the amount of water that can be transferred from a given area.
27. Support assistance programs to aid local entities in developing and implementing groundwater management programs in water transfer source areas.
28. Dredged materials will be analyzed, dredged and handled in accordance with permit requirements. Permits will incorporate mitigation strategies identified in Section 5.3 to prevent release of contaminants of concern.
29. Utilize the criteria and objectives in the Water Transfer Program, in conjunction with existing legal constraints on water transfers, to protect against adverse effects due to water transfers. The criteria for future water transfer proposals include:
    - Water transfers must be voluntary.
    - Water market transactions must result in the transfer or exchange of water that truly increases the utility of the supply, not water that a transferor has never used or water that would have been legally available for downstream use in the absence of a transfer.
    - Water rights of all legal water users must not be impaired.
    - Transfers must not cause overdraft or degradation of groundwater basins, or impair

correlative rights of overlying users.

- Entities receiving transferred water should be required to show that they are making efficient use of existing water supplies.
- Water rights holders (whether districts or individuals) must play a strong role in determining whether water to which they have a right is transferred.
- The beneficial and adverse impacts on fiscal integrity of the districts and on the economy of agricultural communities in source and receiving areas cannot be ignored.

30. Implement seepage control measures.
31. Support local groundwater management that reduces overdraft and third-party effects, including reduction or discontinuation of groundwater pumping.

7.4 Urban Land Use. Implementation of the Preferred Program Alternative may have potentially significant effects on urban land use. These effects may include: (1) Displacement of some existing commercial uses and residents from Program actions located in urban land use areas; (2) Physical disruption or division of established communities; and (3) Potential conflicts of habitat development and storage and conveyance facilities with general plan land use designations or zoning if located in urban use areas.

The following mitigation measures will reduce potential effects of implementation of the Preferred Program Alternative on urban land use:

1. Select and design program actions that minimize the displacement of existing residents.
2. Select and design Program actions that do not physically disrupt or divide established communities.
3. Select Program actions that are consistent with local and regional land use plans. This could include consulting and working with local jurisdictions affected by Program actions early in the planning and environmental review process.
4. Notify all affected persons (for example, residents, property owners, school officials, and business owners) in the project area of the construction plans and schedules. This could include arranging schedules for road detours with residents and businesses to maintain access to homes, schools, and businesses; as well as providing protection, relocation, or temporary disconnection of utility services.
5. Select and design Program actions that do not physically disrupt or divide established communities.
6. Minimize the amount of permanent easement required for construction of facilities and consult with property owners to select easement locations that would lessen property disruption and fragmentation.
7. Relocate roads and utilities prior to project construction to ensure continued access and utility service through the project area.
8. Prepare a detailed engineering and construction plan as part of the project design plans and specifications, and include procedures for rerouting and excavating, supporting, and filling areas around utility cables and pipes in this plan.
9. Verify utility locations through consultation with appropriate entities and field surveys

(such as probing and pot-holing).

10. Reconnect disconnected cables and lines promptly.

7.6 Utilities and Public Services. Implementation of the Preferred Program Alternative may have potentially significant effects on utilities and public services. These effects may include: (1) Need for relocation or modification of major infrastructure components; and (2) Increased risk of gas line rupture during construction.

The following mitigation measures will reduce potential effects of implementation of the Preferred Program Alternative on utilities and public services:

1. Site project facilities and transmission infrastructure to avoid existing infrastructure.
2. Construct overpasses, small bridges, or other structures to accommodate existing infrastructure.
3. Coordinate construction activities with utility providers.
4. Design and operate facilities to minimize the amount of energy required and to maximize the amount of energy created.
5. Design project facilities to avoid or minimize their effect on existing infrastructure.

7.7 Recreation. Implementation of the Preferred Program Alternative may have potentially significant effects on recreation. These effects may include: (1) Temporary closure of recreation areas during construction; (2) Decrease in recreation opportunities and increases in boat traffic in some areas due to speed zone restrictions or prohibition of motorized boating in some areas; (3) More stringent enforcement of boat discharges; (4) Temporary or permanent changes in boating access and navigation; (5) Permanent closure of recreation facilities; (6) Potential decrease in flooded lands suitable for wildlife, hunting, and fishing as a result of water use efficiency actions; (7) Reduced water-contact recreation quality from cold water reservoir releases; (8) Displacement of fish and wildlife and loss of terrestrial and loss of on-stream recreation from new off-stream or expanded on-stream reservoirs; (9) Potential for reduced access to recreation facilities and decreased recreation opportunities from changes in reservoir levels; and (10) Potential short-term construction effects of dredging, such as obstructing or closing channels and creating noise and visual effects.

The following mitigation measures will reduce potential effects of implementation of the Preferred Program Alternative on recreation:

1. Incorporate project-level recreation improvements and enhancements.
2. Work with recreational interests to protect and enhance recreation resources.
3. Conduct an analysis of boating circulation to ensure that appropriate alternative routes are identified and clearly marked if boating circulation in the Delta is to be modified due to temporary, seasonal, or permanent channel closures or to speed restrictions.
4. Identify and mark alternate boating routes.
5. Restoring and designing existing and new levees to accommodate vehicular access and parking for shoreline fishing, boat launching, swimming, hiking, bicycling, and wildlife

viewing where feasible.

6. Maintain boating access to prime areas.
7. Construct portage facilities.
8. Construct boat locks.
9. Provide public information regarding alternate access.
10. Avoid construction during peak-use seasons and times.
11. Post warning signs and buoys in channels.
12. Provide in-kind recreation facilities.
13. Maintain reservoir levels as high as feasible during the recreation season, given regulatory and other operational constraints.
14. Minimize water level fluctuation and establish minimum pool levels.
15. Coordinate operation of all reservoir facilities to minimize adverse reservoir fluctuations in any particular facility consistent with regulatory and other operational constraints.
16. Purchase trail rights-of-way or recreational easements.
17. Provide or improve vehicle access and parking for recreation areas.
18. Provide access to waterfront areas and island edges.
19. Create new day-use boating and camping areas.
20. Relocate or construct new recreation facilities and infrastructure.

7.8 Flood Control. Implementation of the Preferred Program Alternative may have potentially significant effects on flood control. These effects may include: (1) Effects on levee stability from levee and berm vegetation management practices for habitat purposes; (2) Reduced levee stability from habitat restoration using conservation easements along riparian corridors; (3) Increased seepage on adjacent islands, possibly leading to flooding from seepage-induced failure from shallow flooding of Delta islands susceptible to subsidence; (4) Increases in wind-fetched and wave erosion on landside levee slopes from island flooding; (5) Increased levels of flooding downstream of diversions after removal of diversion structures and other obstructions to flow in the Sacramento River tributaries; (6) Increased flood stages along small streams due to increases in the roughness of the stream channel from vegetation on stream banks; (7) Levee slumping and cracking caused by groundwater overdraft and subsidence; and (8) Increased stage upstream of and possible decreased stage downstream from gate structures located in channels that reduce the channel's flood flow conveyance.

The following mitigation measures will reduce potential effects of implementation of the Preferred Program Alternative on flood control:

1. Allow reasonable clearing of deep-rooted trees and shrubs from levee side slopes to support inspection, maintenance, repair, and emergency response, while preserving habitat values.
2. Permit clearing of deep-rooted shrubs and trees on levee side slopes. Trees and shrubs should be allowed to grow only on adjacent berms. If roots penetrate levees, fill materials should be added to levee landside slopes in order to construct a partial setback levee and increase stability.
3. Widen streams downstream of removed water diversion structure to increase conveyance

capacity.

4. Incorporate flood control criteria into the design of stream bank revegetation projects. For example, by increasing the width of vegetated sections to maintain conveyance capacity, the net effect of vegetation on flood control would be negligible.
5. Identify locations susceptible to seepage-induced failure on Delta islands that may be intentionally flooded for habitat.
6. Implement a seepage monitoring program on nonflooded islands adjacent to potential shallow-flooded islands.
7. Develop seepage control performance standards to be used during island flooding and storage periods to determine net seepage caused by shallow flooding.
8. Improve levees to withstand expected hydraulic stresses and seepage.
9. Design erosion protection measures to minimize or eliminate wave splash and run-up erosion.
10. Use rip rap or another suitable means of slope protection to dissipate wave force.
11. Construct large wind/wave breaks in the flooded islands to reduce wind-fetch and erosion potential.
12. Identify existing or planned wells that could affect groundwater and substrate conditions underlying nearby levees or flood control devices.
13. Provide incentives to terminate use of wells that can adversely affect levee stability, reduce their pumping volume to safe withdrawal levels as they affect substrate stability, or otherwise replace them with sources that could not affect levee stability.
14. Design structures to minimize the loss of channel conveyance at gate structures located in channels.
15. Install relief wells near the toes of existing levees on neighboring lands.
16. Construct toe berms with an internal drainage system on neighboring lands.
17. Lower the pool elevation on the storage islands.
18. Develop wetland easements adjacent to levees on neighboring islands.
19. Construct a combination of seep and interior ditches and increase pumping rates, install clay blankets, and install impervious cutoff walls through storage island levees.
20. Control boat traffic in order to reduce boat wakes to levels that will not cause levee or bank erosion.
21. Coordinate erosion protection measures and wave force dissipation measures with the Ecosystem Restoration Program to minimize adverse effects to revegetation efforts.
22. Implement flood management measures including dredging, levee maintenance, and snag removal.
23. Support local groundwater management that reduces overdraft and third-party effects, including reduction or discontinuation of groundwater pumping..
24. Support local agencies in distributing groundwater pumping over a wide region rather than to a concentrated area to minimize drawdown of the aquifer.

7.11 Cultural Resources. Implementation of the Preferred Program Alternative may have potentially significant effects on cultural resources. These effects may include: (1) Effects on cultural resources from construction, excavation, fill and flooding; and (2) Alteration of the

historic setting of a cultural resource.

The following mitigation measures will reduce potential effects of implementation of the Preferred Program Alternative on cultural resources:

1. Conduct cultural resource inventories.
2. Avoid sites through project redesign.
3. Map sites prior to undertaking actions that affect cultural resources.
4. Conduct surface collections.
5. Perform test excavations.
6. Probe for potentially buried sites.
7. Prepare reports to document mitigation work.
8. Conduct full-scale excavation of sites slated for destruction as a result of projects.
9. Prepare public interpretive documents.
10. Document historic structures by preparing Historic Engineering Records or Historic American Building Surveys.
11. Conduct ethnographic studies for traditional cultural properties.

7.12 Public Health and Environmental Hazards. Implementation of the Preferred Program Alternative may have potentially significant effects on public health and environmental hazards. These effects may include: (1) Short- and long-term increases in mosquito breeding habitat from wetland restoration activities and fluctuating water levels; (2) Increased risk of groundwater and surface water contamination from naturally occurring or spilled hazardous materials and from improper handling of hazardous materials; (3) Increased exposure to hazardous materials and waste from construction activities related to storage and conveyance projects and other Program elements; (4) Increases in water quality degradation, resuspension of contaminants, and exposure to hazardous materials from dredging activities; and (5) Increases in levels of methyl mercury released into the Bay-Delta ecosystem from wetland restoration, levee rehabilitation activities and conveyance actions.

The following mitigation measures will reduce potential effects of implementation of the Preferred Program Alternative on public health and environmental hazards:

1. Use various mosquito control methods, such as biological agents, chemical agents, and ecological manipulation of mosquito breeding habitat.
2. Support actions to establish or find funding for mosquito abatement activities.
3. Remove or disturb water that remains stagnant for more than 3 days at a construction site.
4. Limit construction to cool weather, when mosquito production is lowest.
5. Limit construction to periods of low precipitation to avoid pools of standing water.
6. Follow established and proper procedures and regulations for identifying, removing and disposing of contaminated materials.
7. Increase monitoring activities to ensure that groundwater pumping equipment is operating to existing standards.
8. Limit or coordinate construction activities to favorable weather conditions to forestall dispersing hazardous materials.

9. Conduct core sampling and analysis of proposed dredge areas and engineer solutions to avoid or prevent environmental exposure to toxic substances after dredging.
10. Modify engineering plans to minimize mercury related problems.
11. Cap exposed toxic sediments with clean clay/silt and protective gravel.
12. Locate constructed shallow-water habitat away from sources of mercury until methods for reducing mercury in water and sediment are implemented.
13. Use cofferdams to construct levees and channel modifications in isolation from existing waterways.
14. Use sediment curtains to contain turbidity plumes during dredging

7.13 Visual Resources. Implementation of the Preferred Program Alternative may have potentially significant effects on visual resources. These effects may include: (1) Long-term visual effects of new facilities or modified existing facilities; (2) Effects in visually sensitive areas from restoration actions; (3) Degraded watershed views from such actions as erosion control and fire management practices; (4) Creation of borrow pits or spoils material disposal sites associated with storage, conveyance, levee projects, and other Program actions; and (5) Long-term visual effects from construction activities extending more than 5 years.

The following mitigation measures will reduce potential effects of implementation of the Preferred Program Alternative on visual resources:

1. Time changes in flow regimes to minimize "bathtub ring" effects during times of peak recreation use.
2. Minimize construction activities during the peak-use recreation season.
3. Avoid unnecessary ground disturbance outside the necessary construction area.
4. Water areas where dust is generated, particularly along unpaved haul routes and during earth-moving activities, to reduce visual effects caused by dust.
5. Locate and direct exterior lighting for construction activities so that it is concealed to the extent practicable when viewed from local roads, nearby communities, and any recreation areas.
6. Site proposed reservoir(s), if possible, to minimize required cut and fill and locate the reservoir on the flattest topographic section of the site to minimize its visibility.
7. Construct facilities with earth-tone building materials or other visually aesthetic design materials.
8. Revegetate disturbed areas as soon as possible after construction.
9. Locate visually obtrusive features, such as burrow pits and dredged material disposal sites, outside visually sensitive areas and observation sites.
10. Select vegetation type, placement, and density to be compatible with patterns of existing vegetation where revegetation occurs in natural areas. Vegetation such as emergent marsh grasses that can tolerate periodic flooding and drying may be useful.
11. Install landscape screening, such as grouped plantings of trees and tall shrubs, to screen proposed facilities from nearby sensitive viewers.
12. Use native trees, bushes, shrubs, and ground-cover for landscaping, when appropriate, at facilities such as dams and pumping-generating plants, and along new and expanded canals

and conveyance channels, in a manner that does not compromise facility safety and access.

13. Create view opportunities of outstanding features through selective vegetation reduction or constructing roadside viewing areas.
14. Recontour and add vegetation to areas rated as “poor” in variety class.

APPENDIX B

Mitigation Measures Not Adopted in the Record of Decision

Appendix B
Mitigation Measures Not Adopted in the Record of Decision

The following mitigation measures recommended in comments on the Programmatic EIS/EIR are either (1) not adopted because they inappropriate, or (2) rejected as not practicable due to specific economic, technological, or other considerations. The measures are grouped by section from the impact analysis chapters of the Final Programmatic EIS/EIR. Parenthetical references are to the Response to Comments Volume III document appended to the Final Programmatic EIS/EIR.

5.2 Hydrodynamics and Hydraulics

- Provide mitigation strategies aimed at reducing significant impacts to Bay-Delta hydrodynamics and riverine hydraulics (e.g., unacceptable velocity increases) in Section 5.2. (1217-21)

This mitigation measure was not adopted because it is similar to, and therefore duplicative of, mitigation measures already incorporated and adopted in this ROD. Mitigation strategies are not included in Section 5.2 because the section deals only with hydrodynamic and hydraulic modeling. However, the environmental effects resulting from hydrodynamic and hydraulic changes are addressed in other sections of the Final Programmatic EIS/EIR in the context of each of the resources affected. For example, effects on water quality, soils, fisheries and aquatic ecosystems, and flood control and appropriate mitigation strategies are addressed in Sections 5.3, 5.5, 6.1, and 7.8, respectively.

5.3 Water Quality

- Implement source control and offset increasing loads to treatment plants due to water transfers and water conservation as a measure to reduce total dissolved solids (TDS). (1226-D-8)

- Include mitigation strategies for the potential increase in BOC, bacteria, and pathogens from the Ecosystem Restoration Program. (1217-30)

These mitigation measures were not adopted because they are similar to, and therefore duplicative of, mitigation measures already incorporated and adopted in this ROD. To the extent Program actions would result in increases of constituents of concern such as TDS, TOC and pathogens, mitigation strategies in Section 5.3, including treating wastewater at the source, upgrading water treatment processes, and applying agricultural and urban BMPs, will reduce these effects.

- Mitigate the selenium impacts of refineries and municipalities in the North Bay area by assisting with financing a drainage facility for San Joaquin Valley selenium loads. (1349-49)

This mitigation measure was not adopted because it addresses an environmental effect not caused by the CALFED Program. Selenium impacts are not caused by the CALFED Program. This comment addresses existing selenium impacts of refineries and municipal treatment facilities, not CALFED actions. However, CALFED includes actions such as agricultural land retirement in the western San Joaquin Valley to reduce the adverse effects of selenium in order to reach its primary objectives for water quality and ecosystem quality.

- Include mitigation measures to address bromide reduction to the State Water Project, such as real time operational flexibility of the export pumps as a means for reducing export of bromide and salinity. (1230-A-8)

This mitigation measure was not adopted because it addresses an environmental effect not caused by the CALFED Program. Bromide is an existing constituent of concern which enters the Delta through the intrusion of seawater through the Bay, not as a result of CALFED Program actions. However, CALFED includes actions such as real-time management of the export pumps to meet water quality objectives.

5.7 Transportation

- Require future EIRs and EISs for project-specific actions to include traffic assessments and analysis of traffic associated with increases in recreational opportunities resulting from new reservoirs, and other land conversions to recreational uses. (1217-32)

This mitigation measure was not adopted because it is ineffective in mitigating adverse environmental effects. All CALFED project specific actions will comply with the requirements of NEPA and CEQA. Traffic analyses do not mitigate transportation impacts, but they may be used to identify the need for site-specific mitigation measures. To the extent appropriate, traffic analyses may be required for certain project specific actions. However, not every action that increases recreational uses will require traffic analyses, making it inappropriate to adopt this mitigation measure at the programmatic level.

5.8 Air Quality

- Work with local and regional planning jurisdictions to identify areas subject to agricultural land conversion for advance planning for air quality impacts. (1217-33)

This mitigation measure was not adopted because it is similar to, and therefore duplicative of, mitigation measures already incorporated and adopted in this ROD. Mitigation strategies 4, 11, and 21 on page 7.1-2 in the Final Programmatic EIS/EIR address this suggestion.

6.2 Vegetation and Wildlife

- The mitigation strategies should discuss need for additional action at the site specific level if program actions disturb special-status species or protected habitats.

This mitigation measure was not adopted because it is similar to, and therefore duplicative of, mitigation measures already incorporated and adopted in this ROD. This recommendation is addressed by the adopted Mitigation Monitoring Plan discussed in Chapter 9 of the Final Programmatic EIS/EIR and in this ROD. CALFED will monitor all mitigation measures through the Science Program.

7.1 Agricultural Land and Water Use

- Meet Program goals by maintaining land in private ownership, rather than through government purchase.

This mitigation measure was not adopted because it is similar to, and therefore duplicative of, mitigation measures already incorporated and adopted in this ROD. Mitigation strategies 9, 10, and 14 on page 7.1-2 in the Final Programmatic EIS/EIR address this suggestion. (IA7.1.11-15)

- Work with local landowners and organizations in planning and developing projects.

This mitigation measure was not adopted because it is similar to, and therefore duplicative of, mitigation measures already incorporated and adopted in this ROD. Mitigation strategies 4, 11, and 21 on page 7.1-2 in the Final Programmatic EIS/EIR address this suggestion. (IA7.1.11-15)

- Maintain the productivity and flexibility of agricultural lands to the greatest extent practicable when implementing the entire Program.

This suggestion is too general to be an effective mitigation measure as defined by CEQA. However, several mitigation strategies in Section 7.1.11, such as “Restoring existing degraded habitat as a priority before converting agricultural land,” would assist in serving this purpose. (IA7.1.11-15) Therefore, this mitigation measure was not adopted.

- Require buffers when developing habitat projects adjacent to agricultural uses.

This mitigation measure was not adopted because it is similar to, and therefore duplicative of, mitigation measures already incorporated and adopted in this ROD. This recommendation is addressed by mitigation strategy 19 on page 7.1-3 in the Final Programmatic EIS/EIR. Specifics on buffer design must be developed at the site-specific level. (IA7.1.11-16)

- Establish an easement or transfer of development rights program.

This mitigation measure was not adopted because it is similar to, and therefore duplicative of, mitigation measures already incorporated and adopted in this ROD. Further, the State of California already has developed such a program, the California Farmland Conservancy Program that is administered by the Department of Conservation. This is addressed in mitigation strategy 8 on page 7.1-2 in the Final Programmatic EIS/EIR. (IA7.1.11-16)

- Phase implementation of specific Program components.

This mitigation measure was not adopted because it is similar to, and therefore duplicative of, mitigation measures already incorporated and adopted in this ROD. This is addressed by mitigation strategy 17 in Section 7.1.11. This strategy would allow implementation to proceed as needed, rather than happening all at once. (IA7.1.11-16)

- Establish an agricultural mitigation oversight entity to oversee implementation of mitigation by CALFED.

This mitigation measure was not adopted because it is similar to, and therefore duplicative of, mitigation measures already incorporated and adopted in this ROD. This recommendation is addressed by the adopted Mitigation Monitoring Plan discussed in Chapter 9 of the Final Programmatic EIS/EIR and this ROD. (IA7.1.11-15) CALFED will monitor all mitigation measures through the Comprehensive Monitoring, Assessment and Research Program.

- Implement a Planned Unit Development approach to habitat development.

This mitigation measure was not adopted because if is ineffective in mitigating adverse environmental effects. Planned Unit Developments are urban planning designations that allow large tracts of housing or commercial development to set their own development standards outside normal zoning ordinances. The comment provides insufficient information to evaluate how Planned Unit Developments could apply as a mitigation strategy. (IA7.1.11-16)

- Require comprehensive environmental evaluation for projects that will adversely affect agricultural lands, using the NRCS Land Evaluation and Site Assessment (LESA) system.

All CALFED project specific actions will comply with the requirements of NEPA and CEQA. LESA may be used by federal agencies, as appropriate for the scale of project, and can optionally be used by state agencies. LESA is designed to gauge the impacts of urban-type development and may be inappropriate for evaluation of other project specific actions. Therefore, the full or partial use of LESA may or may not be used at the project specific level but is not appropriate at the programmatic level. (IA7.1.11-15)

- Provide development agreements to support remaining agricultural lands when a project results in agricultural land conversion.

It is unclear what type of impact this measure would mitigate. It appears to be a separate

agreement to carry out mitigation measures at the site-specific level. Site-specific mitigation measures will be included in second-tier environmental documents, as appropriate, with the required measures, such as conditions of approval, to monitor such mitigation. It is unclear what purpose would be served by a second document memorializing these mitigations. (IA7.1.11-16)

- Develop specific mitigation measures for the Ecosystem Restoration Program.

This measure is too project-specific for a programmatic document. In developing project specific mitigation measures for project specific Ecosystem Restoration Program actions, CALFED agencies will continue to consider any appropriate measures that help avoid or reduce environmental effects. Because the Ecosystem Restoration Program Plan does not provide project specific information, more detailed mitigation measures for potential effects of project specific actions cannot be determined at this time. The EIS/EIR contains a large number of mitigation strategies for agricultural effects, which must be used by individual project lead agencies in determining mitigation measures for project specific actions. Section 7.1.11 includes 27 mitigation strategies for effects due to agricultural land conversion and local planning impacts; Sections 7.2 and 7.3 include an additional 19 mitigation strategies to reduce adverse agricultural economic and social effects. (IA7.1.11-21)

- Purchase flood easements and repair existing levees rather than developing setback levees.

Decisions on how best to increase flood protection for lands behind specific levees have not yet been made. The Long-Term Levee Protection Plan includes levee strengthening and setback levees as options. (IA7.1.11-16) The merits and liabilities of setting back levees will be closely scrutinized, and the use of setback levees may not be feasible or desirable in many cases. Landowners and other stakeholders will be consulted during project formulation. (LS-4.2-2.) At a programmatic level, the option to use setback levees is included in order to allow flexibility to achieve the primary objectives of ecosystem quality and levee system integrity, depending on the characteristics of the various second-tier levee projects.

- Direct habitat development to poorer quality agricultural soils.

Several mitigation strategies in Section 7.1.11, such as “restore existing degraded habitat as a priority before converting agricultural land,” “focus restoration efforts on public lands before converting agricultural land,” “focus restoration efforts on acquiring lands from willing sellers where part of the reason to sell is economic hardship,” and “use farmer-initiated and developed restoration projects,” would assist in serving this purpose. However, since the various habitat types have specific soils requirements, as do agricultural crops, this measure will not be appropriate for every habitat restoration action. While this measure will be considered for project specific actions, it is not appropriate to adopt this mitigation measure at the programmatic level.

- Reaffirm the state’s right-to-farm policy.

The right-to-farm statute was designed to prevent impacts on agriculture from encroaching

urbanization and generally does not apply to the CALFED Program actions. In addition, reaffirming an existing statute is not a mitigation measure. (IA7.1.11-15)

- Before implementing any action requiring additional water, develop the water source; if water is from former agricultural use, mitigate the significant environmental impact.

CALFED agencies will, by necessity, need to identify and purchase water for projects before that water is applied. That is not a mitigation measure but a practical reality given California's water rights laws. (IA7.1.11-15) Section 7.1 of the Final Programmatic EIS/EIR describes the existing environment as it pertains to agriculture. The environmental effects resulting from a change in water use are addressed in other sections of the Final Programmatic EIS/EIR in the context of each of the resources affected. For example, changes in water use leading to loss of agricultural land or impacts to groundwater levels, water quality or water supply are addressed in Sections 7.1, 5.4, 5.3 and 5.1, respectively. Loss or conversion of agricultural land is considered a significant and unavoidable impact of the Program even though all practicable mitigation measures were adopted to reduce this impact. Economic and social effects of water transfers and other Program actions and ways to reduce these effects are discussed in Sections 7.2 and 7.3, respectively.

- Develop an Agricultural Water Account to mitigate for agricultural water directed to CALFED uses.

While the CALFED Program does not include an Agricultural Water Account, the water supply reliability actions as outlined in Sections 2.2.4 and 2.2.5 of the ROD are intended to provide greater certainty of water supplies for agricultural and other users.

- Pay fair market values.

Payment of fair market values is incorporated as a standard Program policy to minimize economic effects. (See Page 7.2-23.) (IA7.1.11-19)

- Scheduling construction activities to allow harvests.

Scheduling construction activities to allow harvests is incorporated as a standard Program policy to minimize economic effects. (See Page 7.2-23.) (IA7.1.11-19)

- Establish Agricultural Exclusive zoning.

Establishing zoning is a local responsibility. CALFED has no authority to establish local zoning, even in conjunction with the Delta Protection Commission. (IA7.1.11-16) This mitigation measure is therefore not adopted for legal considerations.

- Increase subvention funding and property tax sharing and develop legislation for rural development zones.

Increased subvention funding and property tax sharing, and legislation for rural development zones are outside the abilities of the Program's lead agencies to implement. (IA7.1.11-19) These suggestions are more appropriately directed to the Legislature. This mitigation measure is therefore rejected for legal considerations.

- When conversion occurs, remove Class I and II soils from the habitat site to other agricultural locations.

This measure could hamper ecosystem restoration progress because habitat types have soil requirements similar to agricultural crops. For instance, valley oak woodlands would not grow on hard, poorly drained soils. The costs of moving vast amounts of soils may not be justified by the gains from the receiving parcels and could limit the ability to restore the land to agricultural purposes in the future. Further, additional regulatory hurdles, such as triggering the Surface Mining and Reclamation Act, could make this mitigation even less economically feasible. (IA7.1.11-18) This mitigation measure is therefore not adopted. for economic, legal and technological considerations and because it could cause new adverse environmental effects.

- Require 1 acre of farmland to be protected for every acre converted.

Protection of off-site lands to mitigate conversions of farmlands is addressed in mitigation strategy 8 of Section 7.1. However, the exact amounts to be protected would depend on the project specific effects of conversion, as measured in the second-tier environmental document. The feasibility of this mitigation strategy would also need to be evaluated at the project-specific level, and would depend on the number of voluntary participants in the easement program and the cost of acquiring the easements. (IA7.1.11-18). At a programmatic level, the feasibility of this measure is too uncertain. This mitigation measure is therefore not adopted for technical and economic considerations.

- Adopt a no-net-loss policy for agricultural land.

Because the Program will require agricultural lands in the Delta and elsewhere for Program purposes, a no-net-loss policy as suggested would require at least a 1:1 replacement as mitigation for any agricultural lands converted to Program purposes. This proposed mitigation is not practicable and is therefore not adopted. The cost of purchasing and providing land, irrigation infrastructure, and water as mitigation for agricultural land loss—which direct replacement would require—would make almost any project that is converting agricultural lands infeasible, whether for habitat or urban uses. In addition, irrigation of new lands can cause its own series of environmental effects. Section 7.1.12 describes farmland conversions caused by the Program as a potentially significant environmental effect at the programmatic level. (IA7.1.7-10) The Program objectives to improve and increase terrestrial habitats in order to support sustainable populations of diverse and valuable plant and animal species in the Bay-Delta cannot be achieved without some creation of habitat on land currently used for agriculture. (IA7.1.11-11)

7.12 Public Health

- CALFED must include mitigation to assure that urban water agencies can cost-effectively treat water from the Delta for public health protection since there are no definite plans to construct an isolated facility. (1230-A-3)

This mitigation measure was not adopted because it addresses an environmental impact not caused by the CALFED Program. CALFED actions will not reduce the quality of drinking water nor increase the cost of drinking water treatment. However, CALFED includes source control, water treatment facility improvements and other actions to protect public health.

DRAFT ENVIRONMENTAL IMPACT STATEMENT/
ENVIRONMENTAL IMPACT REPORT

APPENDIX B

U.S. Fish & Wildlife Coordination Act Compliance

United States Department of the Interior

FISH AND WILDLIFE SERVICE
Sacramento Fish and Wildlife Office
2800 Cottage Way, Room W-2605
Sacramento, California 95825-1846

Memorandum JUN 23 2003

To: Director, Mid-Pacific Region, Bureau of Reclamation, Sacramento, California

From: Acting Field Supervisor, Sacramento Fish and Wildlife Office, Sacramento, California

Subject: Draft Fish and Wildlife Coordination Act Report on Implementation of the CALFED Bay-Delta Program, Environmental Water Account

This memorandum constitutes the Fish and Wildlife Service's (Service) draft Fish and Wildlife Coordination Act (FWCA) report, as provided for in section 2(b) of the FWCA (Public Law 85-624; 16 U.S.C. 661-667e), regarding proposed environmentally beneficial changes in operation of the State Water Project (SWP) and the Federal Central Valley Project (CVP). A final FWCA report will be prepared by the Service taking into consideration any new information, once a biological opinion pursuant to section 7 of the Endangered Species Act of 1973, as amended (ESA), has been completed. It is our intent to prepare a final FWCA report to be included in the final Environmental Impact Statement/Environmental Impact Report (EIS/EIR).

Project Description

The August 28, 2000, programmatic ROD for the CALFED Bay-Delta Program (CALFED) established the Environmental Water Account (EWA) as a 4-year cooperative water management program which could be extended by agreement of the participating agencies. The purpose of the EWA is to provide protection to fish species of the San Francisco/Sacramento/San Joaquin River Delta estuary, while simultaneously improving water quality and water supply reliability for water users. Any supplemental water-assets required by the program would be acquired, banked, transferred, or borrowed, substantially through voluntary purchases in the water transfer market, or by developing additional assets over time.

Three alternatives were evaluated in the EWA EIS/EIR: 1) No Action Alternative; 2) Flexible Purchase Alternative; and 3) Fixed Purchase Alternative. Protective measures identified by the proposed action (Flexible Purchase Alternative) range from augmenting instream flows and Delta outflows to reducing Delta export pumping. Changes in SWP and CVP operations to minimize impacts on various fish species residing in or migrating through the Delta could include modifications to the timing of some flow releases from storage and the timing of water exports from Delta pumping plants.

Responsibilities and Evaluation

The Bureau of Reclamation (Reclamation) is the lead Federal agency responsible for compliance with the National Environmental Policy Act (NEPA). Compliance with NEPA and California Environmental Quality Act has resulted in preparation of a draft EIS/EIR. Reclamation is also consulting with the Service pursuant to section 7 of the ESA.

The Service is a Cooperating Agency in the associated NEPA process and has been participating in the planning of this project for some time. As a result, we believe our need for surveys and investigations, as provided for under the FWCA, have been met through existing analyses, completed jointly by Reclamation and the Service. Further, we believe the existing NEPA document sufficiently evaluates the alternatives as presently identified. The Service continues to provide technical assistance to the EWA process through the EWA Environmental Sub-Team and the Action Specific Implementation Plan (ASIP) Technical Sub-Team. The Service has provided comments and recommendations to Reclamation regarding the EWA since September 30, 2002.

Recommendations/Conclusions

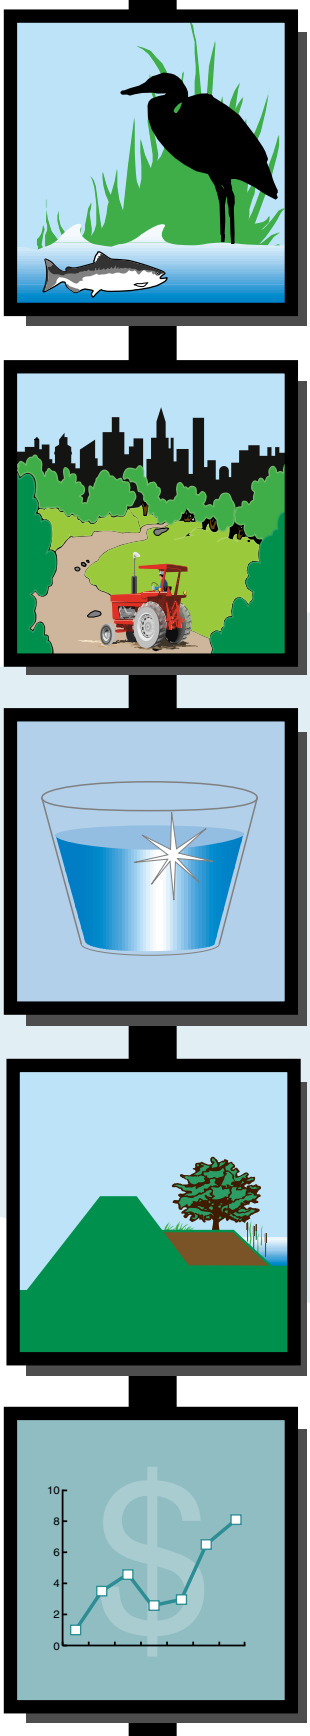
Of the three alternatives evaluated in the draft EIS/EIR, the Service supports adoption of the proposed action (Flexible Purchase Alternative). For a complete description of this alternative, refer to Section 2.4 of the EWA draft EIS/EIR.

The Service and Reclamation are continuing to discuss and resolve any remaining concerns prior to the release of the draft EIS/EIR. However, based on our review of documentation available at the time this memorandum was signed, several issues have yet to be fully addressed within the EIS/EIR. Therefore we recommend the draft EIR/EIS include the following:

1) Compliance and Project Monitoring: A brief but task-specific summary is needed describing the process by which EWA agencies will ensure that all contract provisions and conservation measures will be employed and evaluated. Coordination of water acquisitions, both with other CALFED programs and with non-project water agencies, is central to the success of the EWA program.

2) Effect Indicators and Evaluation Criteria: In order to assess whether or not the EWA will significantly affect species, evaluation criteria must be specific, objective, and grounded in sound science. We believe the EIS/EIR should more clearly and objectively discuss the links between the evaluation criteria and the project effect conclusions.

3) Future coordination under the FWCA should be completed as required for associated tier specific actions.



As required by the FWCA, this report will be coordinated with CDFG and NOAA Fisheries prior to being finalized. If formal comments are received from CDFG or NOAA Fisheries that differ from previous agency input or if the project changes in a way that would adversely affect fish and wildlife resources to an extent not previously analyzed, new analysis will be necessary and mitigation recommendations would provided.

If you have any questions regarding this report or other aspects of the FWCA, please contact Dave Harlow at (916) 414-6600.

APPENDIX C

Environmental Water Account
Operating Principles Agreement

CALFED
BAY-DELTA
PROGRAM

Attachment 2

Environmental Water Account Operating Principles Agreement

August 28, 2000

ENVIRONMENTAL WATER ACCOUNT

OPERATING PRINCIPLES AGREEMENT

The US Fish and Wildlife Service (USFWS), the National Marine Fisheries Service (NMFS) and the California Department of Fish and Game (DFG) (collectively, the Management Agencies), and the US Bureau of Reclamation (Reclamation) and the California Department of Water Resources (DWR) (collectively, the Project Agencies) enter into this Environmental Water Account Operating Principles Agreement on the tools and operations principles for implementing the Environmental Water Account program (EWA) set forth herein and described in the Record of Decision (ROD) for the CALFED Bay-Delta Program to which this Agreement is attached.

Recitals

This Agreement establishes the Environmental Water Account (EWA) program, sets forth the EWA's general operating principles, and describes the tools which are available for use by the EWA. The EWA is a cooperative management program whose purpose is to provide protection to the fish of the Bay–Delta estuary through environmentally beneficial changes in the operations of the State Water Project (SWP) and federal Central Valley Project (CVP), at no uncompensated water cost to the projects' water users. The EWA is intended to provide sufficient water, combined with the Ecosystem Restoration Program and the regulatory baseline, to address CALFED's fishery protection and restoration/recovery needs. This approach to fish protection requires the acquisition of alternative sources of project water supply, called the "EWA assets," which will be used to augment streamflows, Delta outflows, to modify exports to provide fishery benefits and to replace the regular project water supply interrupted by the changes to project operations. The replacement water will compensate for reductions in deliveries relative to existing facilities, project operations and the regulatory baseline as defined in the CALFED Record of Decision that result from EWA actions.

These principles are intended to apply generally, but may not provide the necessary direction in all circumstances. Issues will be resolved as they arise by mutual agreement among all five signatory agencies.

The five state and federal agencies that execute this agreement will have responsibility for implementing the EWA. The Management Agencies will manage the EWA assets and will exercise their biological judgment to determine what SWP/CVP operational changes are beneficial to the Bay-Delta ecosystem and/or the long-term survival of fish species, including those listed under the State and Federal Endangered Species Acts. The Project Agencies will cooperate with the Management Agencies in administering the EWA, including banking, borrowing, and conveyance of EWA assets and making the operational changes proposed by the Management Agencies. The Project Agencies will also be responsible for acquiring EWA assets for the first year.

This Agreement is consistent with the regulatory responsibilities, statutory authorities, including CVP and SWP project purposes, of the five state and federal agencies. After the first year, acquisitions may be made pursuant to a public process that may employ other agencies or third parties to acquire assets.

Article I.
ESTABLISHMENT OF THE ENVIRONMENTAL WATER ACCOUNT PROGRAM

1. Establishment

The Management Agencies and Project Agencies hereby establish the Environmental Water Account program (EWA) to be implemented in accordance with the Operations Principles and using the Tools set forth hereunder. Each of the Management Agencies and Project Agencies will appoint an EWA coordinator.

2. Initial and Annual Assets

The Management Agencies and Project Agencies will take the following actions to acquire the initial assets for the EWA, and will take all necessary and appropriate steps to acquire them each year thereafter. Assets acquired under sub-articles a-d, below, will vary from year to year depending on hydrological and regulatory conditions, and are therefore not certain. The tools used to acquire the assets are described in Article III of this Agreement. Other tools may be developed as appropriate to acquire functionally equivalent assets

a. SWP Pumping of (b)(2)/ERP Upstream Releases

As provided in Article III.1.b.i, the current modeling indicates that the average annual value of this asset is approximately 40,000 acre-feet.

b. EWA Use of SWP Excess Capacity

As provided in Article III.1.b.ii, the current modeling indicates the average annual value of this asset is approximately 75,000 acre-feet.

c. Export/Inflow Ratio Flexibility

As provided in Article III.1.b.iv(B), the current modeling indicates the average annual value of this asset is approximately 30,000 acre-feet.

d. 500 cfs SWP Pumping Increase

As provided in Article III.1.b.iv(A), the current modeling indicates that the average annual value of this asset is approximately 50,000 acre-feet.

e. Water Purchases

The Project Agencies shall acquire from willing sellers each year 150,000 acre-feet of water from sources south of the Delta and at least 35,000 acre-feet of water from sources upstream of the Delta or their functional equivalents. The upstream-of-Delta purchases may grow in subsequent years. These purchases shall be arranged so that assets may be kept in storage for the entire water year, until such time as the EWA managers release the assets to compensate for an EWA action, or until they are transferred to other EWA storage facilities.

f. One-time Acquisition of Stored Water Equivalent

In order to launch the EWA and to provide sufficient collateral as defined in Article II.2.c.i of this Agreement for the EWA to function as intended, the Project Agencies shall acquire 200,000 acre-feet of stored water or its functional equivalent from south-of-Delta sources. This water is intended to be used as collateral for borrowing, and will be released only when all other assets have been expended. The related storage is intended to function as long-term storage space, including after the water has been released. Provided the asset's function is not impaired, the acquisition of this asset may take any number of forms, including without limitation such transactions as source shifting, or reductions in contractor deliveries.

g. Source Shifting Agreement

The Project Agencies shall arrange with one or more of their contractors to use water totaling at least 100,000 acre-feet from either an alternative source, or at a subsequent time, to allow for storage of the project water in San Luis Reservoir as an EWA asset or to enable an operational curtailment without causing a summer "low-point problem." The EWA will repay this water during the initial 4-year term of the EWA, unless other arrangements are made. Upon repayment, the opportunity to employ the source-shifting tool will become available again.

3. Definition of Operational EWA

As described in Endangered Species Act biological opinions, Conservation Agreement, Record of Decision , the Project contractors will receive certain commitments if, among other things, there is an operational EWA. The EWA shall be considered operational in any one year when the one-time 200,000 acre-feet of stored water equivalent has been acquired and when: 1) the EWA includes deposits of the 185,000 acre-feet of purchased water as described above; 2) a source-shifting agreement of at least 100,000 acre-feet; and 3) the variable tools (items 2a-d above) are all in place. The Management and Project Agencies shall make all attempts to have all items in place by December 31, 2000, so that ESA commitments may be provided to the water users.

4. Science Review Panel

The CALFED Science Program will convene a scientific panel familiar with the EWA and its operations. The Management Agencies and Project Agencies will keep this panel informed on a monthly basis through the CALFED Ops Group reporting process.

The panel will convene on an annual basis to review the EWA operations.

5. Term

The EWA shall expire on September 30, 2004 and any remaining assets shall revert to the Project Agencies, unless the EWA is extended by written agreement among the Management Agencies and Project Agencies and the assets remain in the EWA. The EWA may be terminated at any time if all five signatory agencies execute a written agreement to do so.

6. Continuation of EWA

Before the EWA expires, the Management Agencies and Project Agencies will assess the success of EWA operations and analyze the potential impacts from new facilities and expanded conveyance capacity. The Agencies will then determine the appropriate size and composition of an EWA, as well as the EWA's sharing in the benefits from new facilities, in the fifth and future years.

Article II
General Operational Principles

1. The Management Agencies and Project Agencies Shall Cooperate to Implement the EWA

a. Curtailments and Borrowing

The Project Agencies shall make the operational curtailments and agree to the borrowing transactions proposed by the Management Agencies that are consistent with these principles and this Agreement.

b. Acquisitions and Banking

The Project Agencies shall acquire the EWA assets from willing sellers in the first year. The Project Agencies and Management Agencies will establish EWA water banking and accounting mechanisms consistent with the intended EWA fishery benefits and ESA commitments.

i. Manner of Acquiring and Holding EWA Assets

The Project agencies shall, in consultation with the Management Agencies, acquire, hold, and deal with the EWA assets they acquire in a manner that serves the purposes of the EWA program.

ii. Release of Assets

The acquisition and banking arrangements made for EWA assets shall provide for their unconditional release to the Projects or to the Projects' designees upon approval by the Management Agencies.

c. Use of Project Water Rights

The Project Agencies shall use their respective water rights to acquire EWA assets to the greatest extent permitted by State and federal law, including California water rights law, and by the requirements of their respective water supply and other contracts. If changes to these or other water rights are needed to acquire, transfer, or release EWA assets, the Project Agencies shall take timely steps to secure those changes in accordance with State water law. The Project Agencies shall cooperate in all water rights actions and matters to optimize their flexibility in acquiring, conveying, storing and releasing EWA assets.

d. Use of CALFED Ops Group

The Management Agencies and the Project Agencies shall participate in the CALFED Ops Group to report regularly on the EWA's operations, to help resolve issues that may arise, and to communicate with stakeholders. Whenever issues affecting the interests of non-signatory parties arise, such parties shall be afforded the opportunity to fully participate in the resolution of those issues.

e. Exchange of EWA Assets

If the Management Agencies decide to do so, the Project Agencies may exchange EWA assets for assets of a character, such as location, seasonality or year-type, more suitable to EWA purposes.

f. Sale of EWA Assets

When storage capacity for EWA assets is not available or EWA assets are otherwise subject to loss, the Management Agencies may direct the Project Agencies to sell EWA assets which are not at that time pledged or identified for release under these Principles. No other benefits may be conferred to the EWA as a result of such sales. Any provisions for transfer or conveyance of assets sold or being sold shall not be governed by these principles. The proceeds of sale of EWA assets shall be accounted for and, to the extent provided by law, remain as EWA funds.

g. Coordination

The Management Agencies and the Project Agencies will hold regular meetings to share information and ideas and will coordinate their respective activities to optimize the implementation of the EWA.

h. Coordinated Operations Agreement

The Project Agencies shall continue to adhere to the general sharing principles contained in the 1986 Coordinated Operations Agreement (COA) as modified by interim operating agreements to reflect changes in regulatory standards, facilities, and operating conditions, including the EWA.

Implementation of the EWA shall not establish precedents for future negotiations or modifications of the COA. Future negotiations or modifications of the COA shall not inhibit effective EWA implementation.

2. EWA Shall Cause No Reduction in Project Deliveries

a. Except Where Contractor Agrees

The principles under this Article shall all be subject to the qualification that reductions in deliveries shall be allowed where the affected contractor or contractors agree to them, as in the case of source-shifting agreements.

b. No Harm To Deliveries Principle

The intent of the EWA is to provide substantive fishery protections by taking advantage of project flexibility. The use of EWA assets to compensate for operational curtailments shall not change the timing, location, or amount of water deliveries the projects would have made to its users operating under the Regulatory Baseline in the absence of the EWA. Reference in these Principles to "reductions in deliveries" shall include only uncompensated changes in timing, location, or amount of deliveries. In the operation of the EWA, it is the intent of the Project Agencies and Management Agencies to minimize water quality impacts associated with EWA operations.

i. "Operational Curtailment"

An operational change at the Delta CVP/SWP facilities, pursuant to the Management Agencies' request, that causes a reduction in Project south-of-Delta water exports beyond the regulatory baseline for existing facilities as established in the Record of Decision, is referred to in these Principles as an "operational curtailment."

ii. Identification of Asset For Release

At the time of every operational curtailment, the Management Agencies must identify an asset sufficient to provide replacement water for any potential reductions in deliveries to contractors. When necessary to ensure no reductions in deliveries, such EWA assets shall be released to the Projects to allow delivery in the same amount and at the same time and place as the foregone export.

iii. Time of Release of Asset

Except when project water is borrowed, the EWA asset identified for release to the affected project shall be released no later than the time the proposed operational curtailment is implemented. "Released" means that the asset becomes available to and the unconditional property of the affected project or its designee and is no longer held for EWA purposes.

iv. Delta Smelt Export/Flow Ratio

The reduced exports necessary to achieve the annual spring 2:1 Vernalis- flow-to-Project-export ratio required by the 1995 USFWS biological opinion for Delta smelt shall be provided from either EWA assets and/or CVPIA Section 3406(b)(2) yield dedication.

v. Cross Channel Gate Closure

Impacts on project deliveries of any closure of the Delta Cross Channel Gates pursuant to State Water Resources Control Board (SWRCB) Decision D-1641 or any future decision implementing those objectives in the SWRCB's 1995 Water Quality Control Plan allowing for discretionary Gate closure for fishery purposes shall be attributed to the Regulatory Baseline. Recognizing potential conflicts that may arise during dry conditions, the Project Agencies and the Management Agencies will ensure full consideration of all appropriate factors required for a decision based on the then-available best scientific data and evaluation, particularly including water supply, water quality, and endangered species as well as tradeoffs. The EWA shall compensate the Projects pursuant to these principles when the Management Agencies advise Reclamation to close the Gates for a time outside such regulatory baseline conditions and such closure leads to export reductions.

c. Borrowing; No Reduction in Deliveries

The EWA may borrow water from the SWP or CVP to achieve fishery protections upon their approval, provided that such borrowing will not result in any reduction in deliveries. Borrowing against EWA assets shall cause no reduction in deliveries in the year of borrowing or in the subsequent water year.

i. Identification and Pledge of Asset As Collateral

When the Management Agencies borrow project water to implement an EWA fishery action, they shall identify and pledge as a guaranty collateral sufficient to provide replacement water for any potential reductions in deliveries to contractors in the same amount and at the same time as the borrowed water would have been delivered.

ii. Sufficiency

The Project Agencies shall assess sufficiency of the collateral, in part, on the likelihood that the borrowed water will be replaced naturally by virtue of the wetness of the year. Thus, foreseeing favorable hydrology, collateral need not be in existence at the time of borrowing, but may consist of the EWA's ability to provide replacement water with later-acquired assets to assure no reduction in project deliveries should actual circumstances turn out to be different from those foreseen.

iii. Project Allocations and Deliveries

When project water has been borrowed from storage, project allocation and delivery decisions shall be made as if the water had not been borrowed.

iv. Disencumbering of Collateral or Release of Asset

Each borrowing transaction shall explicitly describe the conditions upon which the identified collateral will either be disencumbered or released to project water supply. "Disencumbered" means no longer serving as collateral subject to release under the borrowing transaction.

v. "Year"

Unless otherwise indicated, as used throughout these Principles, "year" means "water year", beginning on October 1 and ending on September 30.

vi. Project Borrowing From EWA

The projects may borrow from EWA assets on the condition the borrowed water shall be repaid when or before the EWA needs it to cover an operational curtailment.

d. Use of Excess Capacity

The EWA shall be entitled to use excess capacity in SWP or CVP conveyance facilities, on an equal priority with Level 4 acquisitions mandated by the CVPIA.

i. "Excess Capacity"

"Excess capacity" means capacity available after project operational requirements and contract commitments have been met. In the case of the SWP, it also means after any wheeling for SWP contractors and any wheeling of CVP water for delivery to federal contractors for whom the SWP has traditionally wheeled water: San Joaquin National Cemetery, Musco Olive Co. and the users of the Cross Valley Canal.

ii. Exception to the Principle

There is one exception to the general principle that the EWA shall cause no reduction in project deliveries, and to the specific principle that only the excess of the SWP's current conveyance capacity is available to the EWA: the SWP's equal sharing with the EWA of b(2) and ERP upstream releases that the SWP could otherwise have pumped and used itself. This sharing is one of the EWA tools.

e. Banking in Project Reservoirs

EWA assets may be stored, or "banked", in project reservoirs upstream of the Delta and in San Luis Reservoir, provided the Projects do not incur any additional adverse operational impacts.

i. Priority of EWA to Project Storage

Unless the Management Agencies and the Project Agencies make other arrangements, EWA assets will have a lower priority for storage space in project reservoirs than regular project storage and thus will be released first. Regular project storage includes reservoir operations for project purposes, such as flood control, downstream temperature control, minimum downstream flows for fish, regulatory requirements, and contract water supply including contractor carryover water.

SWP Use of Federal Share of San Luis. Pursuant to Supplemental Agreement No. 1 for the Operation of the San Luis Unit, during the term of this Principles Agreement, the CVP shall give precedence to EWA water for storage in the unused share of San Luis Reservoir. The CVP shall agree to allow the SWP to use its share of storage in San Luis Reservoir only to the extent that such use does not impair operation of the EWA.

ii. Protocols or Standards For Storage, Spill, and Loss of EWA Water In Upstream Project Reservoirs

In light of the difficulty and complexity of accounting for the storing of other than regular project water in a multi-purpose reservoir, the Project and Management Agencies shall jointly establish reasonable and practical standards or protocols for determining when an EWA asset may be stored and when it would spill or be lost from upstream project storage.

iii. Consequential EWA Upstream Storage

Where an EWA asset is used to pay for an operational curtailment limiting the export of project stored water, the project water that remains in storage as a consequence shall become an EWA asset. The conversion of project water to EWA water shall occur only to the extent that EWA storage could otherwise have taken place within the regular project operational and regulatory constraints of the reservoir, to be determined in accordance with the protocols and standards developed by the affected Project Agency.

f. Agreement on Further Conditions and Requirements; Water Accounting

The Project Agencies and the Management Agencies shall enter into an agreement that further specifies, to the greatest degree practicable, the conditions and requirements upon which: assets are to be released to the projects to compensate for operational curtailments; borrowing may occur; collateral for borrowing is to be disencumbered or released; and water transfers and exchanges may take place. Provisions for forecasting EWA actions, accounting for EWA assets and for all project water impacted by the EWA, including impacts to coordinated CVP/SWP operations, should be included in this agreement.

3. No Increased Costs

EWA shall impose no net, increased incremental costs upon the projects. The Management Agencies and Project Agencies shall develop a financing plan to cover all costs of the EWA from non-contractor funding sources. The plan may include the establishment of a revolving account with annual deposits to pay for fluctuating EWA costs. The plan shall address increased Project operating costs, both power and ancillary costs, of both the SWP and CVP resulting from implementation of the EWA; crediting the EWA as appropriate for reduced operating costs; crediting the EWA for certain power benefits; and revenues realized from the sale of EWA assets. The Management Agencies and Project Agencies shall develop and recommend this plan, including any necessary legislation, to the CALFED Policy Group within 90 days following the adoption of the ROD.

Considering the importance of acquiring water to the success of the EWA, the Project Agencies and Management Agencies shall meet and confer to develop alternatives for funding power and other incidental EWA costs, if such costs interfere with the successful operation of the EWA.

4. The EWA Shall Be Responsible For Mitigating Its Water Quality, Water Rights, and Environmental Impacts As Required By Law

Article III
Description of the EWA Tools

The following are the EWA tools for acquiring and using alternative sources of project water supply to offset the effects of operational curtailments imposed under the EWA program so that project deliveries will not be affected. While the requirements have been described in Article I (Establishment), any additional tools or arrangements that are determined to be beneficial to the EWA may be acquired at the discretion of the Management Agencies and Project Agencies.

1. Acquisition of Water for the EWA

a. Purchases

The Project Agencies (who are initially designated to undertake the purchases of EWA assets) will use EWA funds to purchase EWA assets from willing sellers both upstream and south of the Delta. "South of the Delta" means the export service areas served by the projects' Delta pumping plants, and may include Project contractors. "Upstream of the Delta" includes the legal Delta itself, as well as all tributaries to the Delta. Purchases can include leases, options, long-term agreements, and any other property or contractual transaction that makes alternative project water supplies available south of the Delta or available for conveyance to south of the Delta. In addition to direct diversion and stored water supplies, purchases will include the acquisition of storage space in both surface reservoirs and groundwater basins to bank EWA assets.

Explicit provision will be made in the purchase transaction for calling upon the asset and releasing it to provide water to replace project deliveries as needed to offset the impact of an EWA operational curtailment. The Agencies will coordinate EWA water acquisition with Level 4 refuge water acquisitions to ensure the priority accomplishment of both each year.

b. Delta Operations

There are four tools involving Delta project operations under which ESA water assets are to be acquired.

i. Sharing of b(2) and ERP Water Pumped by the SWP

The SWP and the EWA will share, on a 50-50 basis, water:

(1) which has been released from storage or is otherwise made available for upstream purposes

under either CVPIA Section 3406(b)(2) or the ERP and arrives in the Delta with no further ERP or b(2) purposes to serve;
(2) which exceeds the export capacity of the CVP Tracy pumping plant;
(3) for which the SWP and EWA both have demand south of the Delta; and
(4) which the SWP has capacity to pump.

Pumping of b(2) or ERP water where either the SWP or the ERP is demand-limited south of the Delta (i.e., there is no place for the water to go) will not count against the 50% share of the one which does have demand for the water.

ii. Joint Point: SWP Wheeling of CVP and EWA water

The SWP will use excess capacity it may have at its Banks pumping plant to pump water for both the CVP and the EWA, to be shared between them on a 50-50 basis. The CVP water could be either from storage or under its Delta water rights to divert unstored water. The EWA water could be either from non-project water acquired north of the Delta, or stored or unstored water pumped under CVP or SWP water rights. If either the CVP or EWA is demand-limited, the other's use of joint point will not count against its 50% share.

"Joint Point" is a term that is used in recent SWRCB Delta proceedings and decisions (e.g., WR 95-6; WR 98-9; D-1641) to refer to the ability of the SWP and CVP to utilize each other's point of diversion in the south Delta, i.e., their points of diversion may be used "jointly". It is used here, however, in a slightly different way, to refer to the use (mainly) of the SWP point of diversion *alone*; and, specifically, to the wheeling of EWA as well as CVP water.

Use of excess capacity for the EWA, CVP, and Level 4 refuge water will take precedence over all other non-project pumping, except, as noted above, for wheeling water to respond to facility outages and wheeling to supply CVP contractors for whom the SWP has traditionally wheeled CVP water, namely, San Joaquin National Cemetery, Musco Olive Co. and the users of the Cross Valley Canal.

iii. SWP Appropriation of Unregulated Flow

The SWP may use its own Delta diversion rights to pump water from the Delta for EWA purposes when the SWP has capacity but no demand. It would be used in cases where Joint Point could also be used but where it would be preferable to create EWA assets south of the Delta to offset SWP rather than CVP losses to operational curtailments. As an adjunct to Joint Point, it would simply utilize SWP rather than CVP water rights to pump excess flows for the EWA's share. It would not affect the CVP's own share of excess SWP capacity.

iv. Project Pumping Made Possible by Regulatory Relaxations

(A) Relaxation of the Section 10 Constraint

The SWP is limited under Section 10 of the Rivers and Harbors Act, pursuant to US Army Corps of Engineers (Corps) Public Notice 5820-A, to a three-day average rate of diversion of water into Clifton Court Forebay of 13,250 acre-feet per day. This is equal to

an average, around-the-clock diversion rate of 6,680 cfs. (That rate may be increased during winter months when the San Joaquin River flow is above 1,000 cfs.)

Permission has been obtained from the Corps to increase the base diversion rate by the equivalent of 500 cfs to 7,125 cfs for the months of July, August, and September, through 2002. This 500 cfs will be dedicated in its entirety to pumping for the EWA.

(B) Relaxation of the Export/Inflow Ratio

Under D-1641, and anticipated under the SWRCB order to be issued upon completion of the Bay-Delta water rights hearing, project exports are limited at different times of the year to a certain percentage of Delta inflow (usually either 35% or 65%). This limitation is called the Export/Inflow, or E/I, ratio. Both D-1641 and the 1995 Water Quality Control Plan, consistent with the 1994 Principles for Agreement (Bay-Delta Accord), allow for these ratios to be relaxed upon the meeting of certain requirements.

Relaxations of the E/I ratio will be sought as appropriate and used to create EWA assets south of the Delta.

2. Banking of EWA Assets

a. Generally

Generically, banking is the storing for later use of water that would otherwise be used or lost in the present. Water can be banked and used within the same water year or carried over for use in a subsequent water year. Even though the acquisition of stored water does not carry the idea of converting a transitory asset into a durable asset, it is included here as an EWA banking transaction as well as a species of EWA asset acquisition. Like the acquisition of assets, banking transactions must provide for access to and the release of the stored EWA assets to the projects.

Priority of EWA assets in storage generally will turn on the provisions of the banking document. Usually, if imported water is physically stored in a groundwater basin, it will have a first and exclusive right to the water stored. If EWA water is stored in a surface reservoir, it usually will be junior to other rights and will spill first.

Banking EWA water south of the Delta should have the highest priority in importance, in that it creates assets which are both durable and which may be released without the ability to move water from the Delta being an issue.

b. Banking in Project Reservoirs

EWA water may be stored in project reservoirs upstream of the Delta as well as in San Luis Reservoir, with a lower priority than regular project water. The EWA will share this storage priority with water acquired for Level 4 refuge needs.

c. Source-Shifting Agreements

The purpose of water banking is to have water available for use at a time other than its original availability. Source-shifting agreements fall under this functional definition of "banking". Source-shifting (or "demand-shifting") agreements are agreements with a water agency, like MWD, which are able, at certain times, to call on non-Delta sources of water to temporarily create an asset for use by the EWA. These assets can be used for EWA operational curtailments. Replacement of the source-shifted water occurs at an agreed-upon subsequent time without any incremental impacts to the Projects.

3. Borrowing

Borrowing of project water, specifically water in San Luis Reservoir, is a tool intended to enhance the effectiveness and use of EWA assets. Project water in San Luis Reservoir may be borrowed to support an operational curtailment in lieu of immediately releasing an EWA asset, where the borrowed water is not needed at that time to make project deliveries, to avoid water quality and supply problems associated with the San Luis low point, or to satisfy reasonable carryover storage objectives.

An appropriate EWA asset will be pledged to assure that, if the borrowed water is not otherwise made up, release of the pledged asset will cause project deliveries not to be affected by the borrowing transaction.

4. Transfers and Delta Conveyance

Transfers will be used mainly to create assets south of the Delta out of assets upstream of the Delta. They can also be used to make acquisitions south of the Delta suitable for release to project use, where a change in the legal place or purpose of use or point diversion of the water is needed.

IV.
Additional Provisions

1. Contingent on Appropriation or Allotment of Funds

The expenditure or advance of any money or the performance of any obligation of the United States or the State of California under this Agreement shall be contingent upon appropriation or allotment of funds. No liability shall accrue to the United States or the State of California for failure to perform any obligation under this Agreement in the event that funds are not appropriated.

The project schedules described in this document depend upon certain assumptions about state and federal budgets, optimized construction schedules, willing sellers and other contingencies. These assumptions may change as the CALFED Program progresses and appropriate revisions to

the CALFED Program may be necessary. Consistent with federal law, nothing in this document constrains the discretion of the President or his successor from making whatever budgetary or legislative proposals he or his successors deem appropriate or desirable.

2. Modification Only By Written Agreement

The terms of this EWA Operations Principles Agreement may be modified by written agreement executed by all parties.

Having considered the contents of this document, its attachments and the documents supporting this decision, we hereby adopt these Principles.

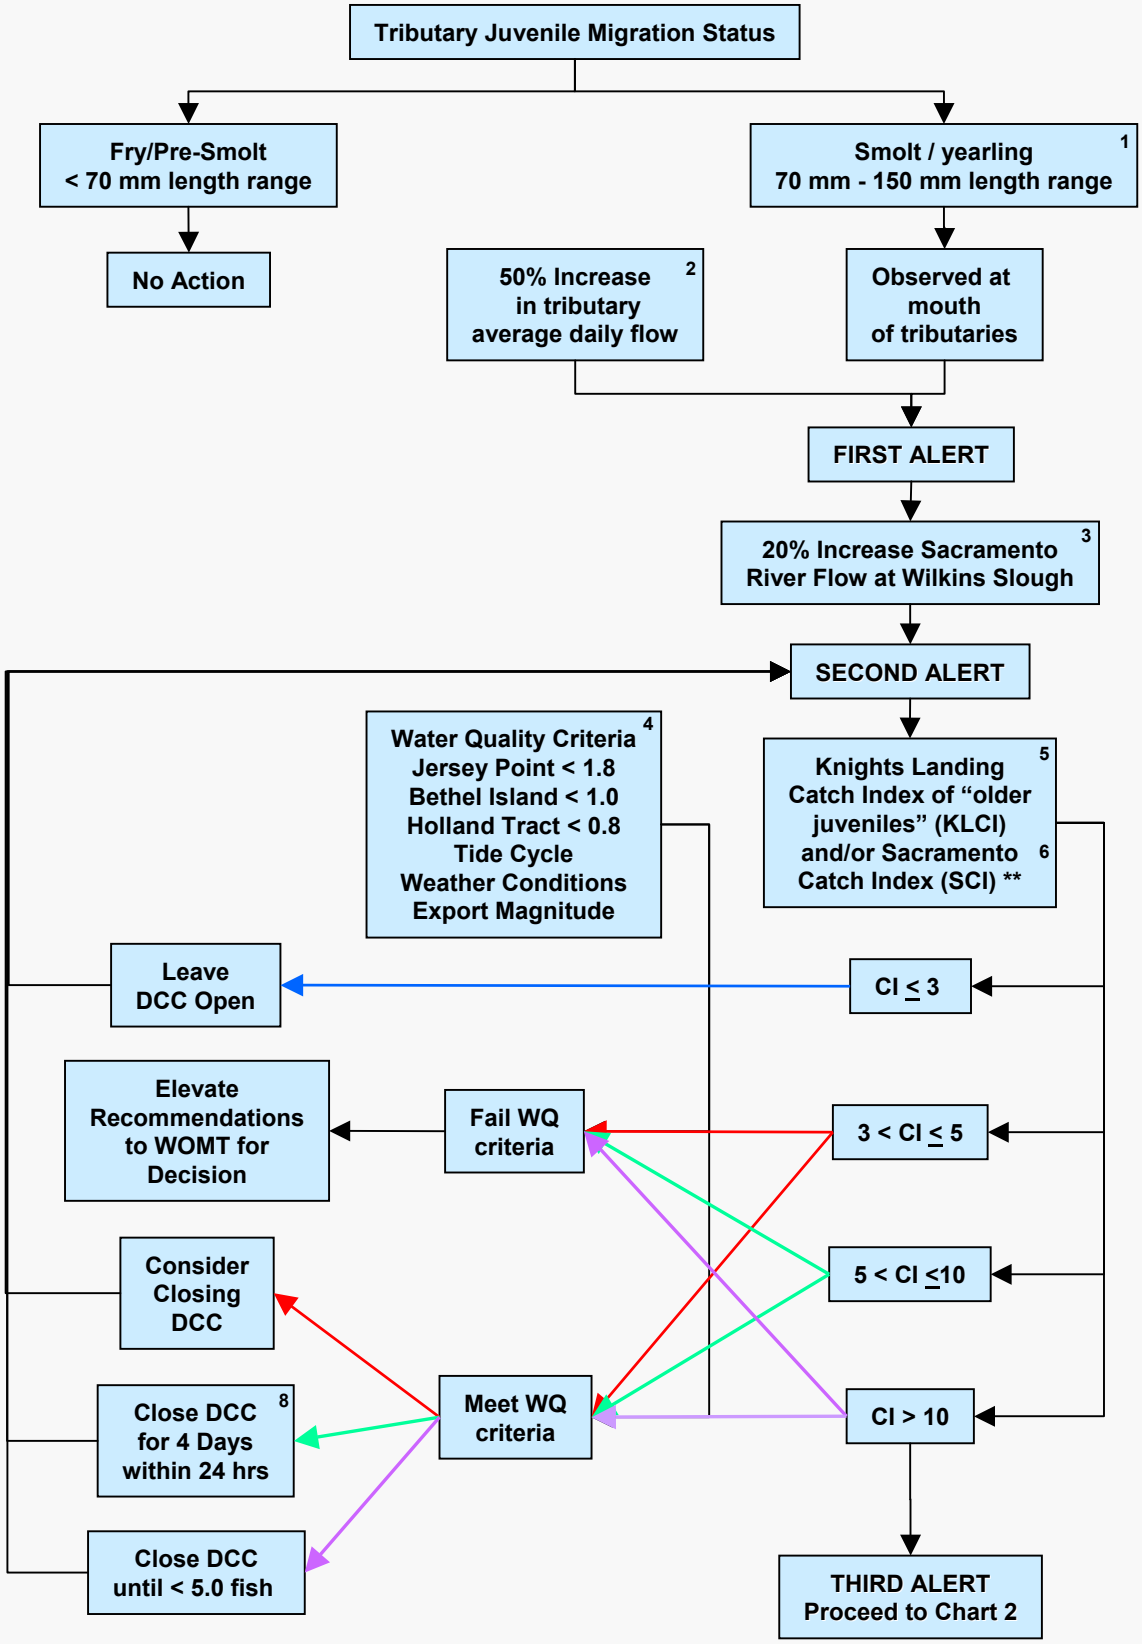
DRAFT ENVIRONMENTAL IMPACT STATEMENT/
ENVIRONMENTAL IMPACT REPORT

APPENDIX D

Fish Decision Trees

Table 2 The Delta Smelt Decision Tree



Life stage	Adults
Timing	Pre-VAMP (February 1 through April 15)
Concerns	1) High relative densities of adults in the south Delta are a concern due to the potential for increase entrainment at the SWP and CVP.
	2) High relative densities of delta smelt in the south Delta also suggest spawning may occur in the south Delta, increasing the chances for exceeding the red light level[a] of incidental take in the late spring and early summer.
Data of interest	Before pre-VAMP, consider fall midwater trawl indices
	Spring midwater trawl
	Salvage
	Beach seine
	Chipps Island trawl
	Hydrology (wet or dry year; placement of X2)
	Water quality conditions and water temperature
	Condition of the fish
Assessment of conditions	Adult distribution in Delta and downstream of the Delta
	Salvage levels/densities, yellow light
	Potential high numbers in juvenile salvage if high numbers of adults are concentrated in the south Delta
Tools for change	Reduction in exports, either concurrently at both facilities or at the facility that is salvaging the most fish
Biological questions using the available data	1) Is the adult distribution broad or not?
	2) Is salvage elevated or not?
	3) Is previous FMWT index high or low?
	4) Are water quality conditions (e.g. water temperatures) conducive to spawning?
	5) Are fish ripe for spawning? (Both of above may help determine if there will be a protracted spawn.)
Questions concerning operations	1) Is there a need to reduce exports at either or both facilities based on either the distribution of adults and/or an increase in the salvage of adult delta smelt?
	2) Is it likely to be a difficult spring or summer? That is, do we expect high levels of delta smelt salvage in the spring or summer?
Assessment of concern	I. If the stated recovery criteria index is lower than 239, then concern is high.
	II. If distribution information shows adults delta smelt are concentrated in the south and central Delta, then concern is high.
	III. If the observed or predicted salvage of adults increases sharply, then concern is high.
	IV. If fish at the salvage facilities are on the verge of spawning and temperatures are conducive to spawning, then concern is high.
Recommendations	A) If concern is high and salvage increases abruptly, then recommendations for action is likely.
	B) If the observed or predicted salvage is at or approaching the red light or at the yellow light, then a recommendation for action is likely.
	C) If assessments II and I are true, then we expect a difficult spring or summer (June and July).
Life stage	Larvae
Timing	VAMP (April 15 through May 15)
Concerns	High numbers of larvae in the south Delta will likely result in higher numbers of fish rearing to juvenile stages and higher levels of entrainment.
Data of interest	Light traps surveys
	20-mm survey[b]
	Water temperatures
	Salvage[c]
	Hydrology (wet or dry year; placement of X2)
Assessment of conditions	Spawning distribution
	Percent distribution

[a] Yellow light and red light as defined in the 1995 OCAP opinion.
[b] If fortnightly 20-mm survey is occurring and red light occurs, then effort will increase to weekly sampling.
[c] Salvage levels at this time will likely not reflect the number of delta smelt in the south Delta, since smelt begin to be counted at the salvage facilities at about 25 mm.
[d] The barriers shall be operated as stated in the USFWS biological opinion (1-1-96-F-53), April 26, 1996.
[e] Changes considered under “a” and “b” would aim to increase net positive flows in Old and Middle rivers downstream of the export facilities.

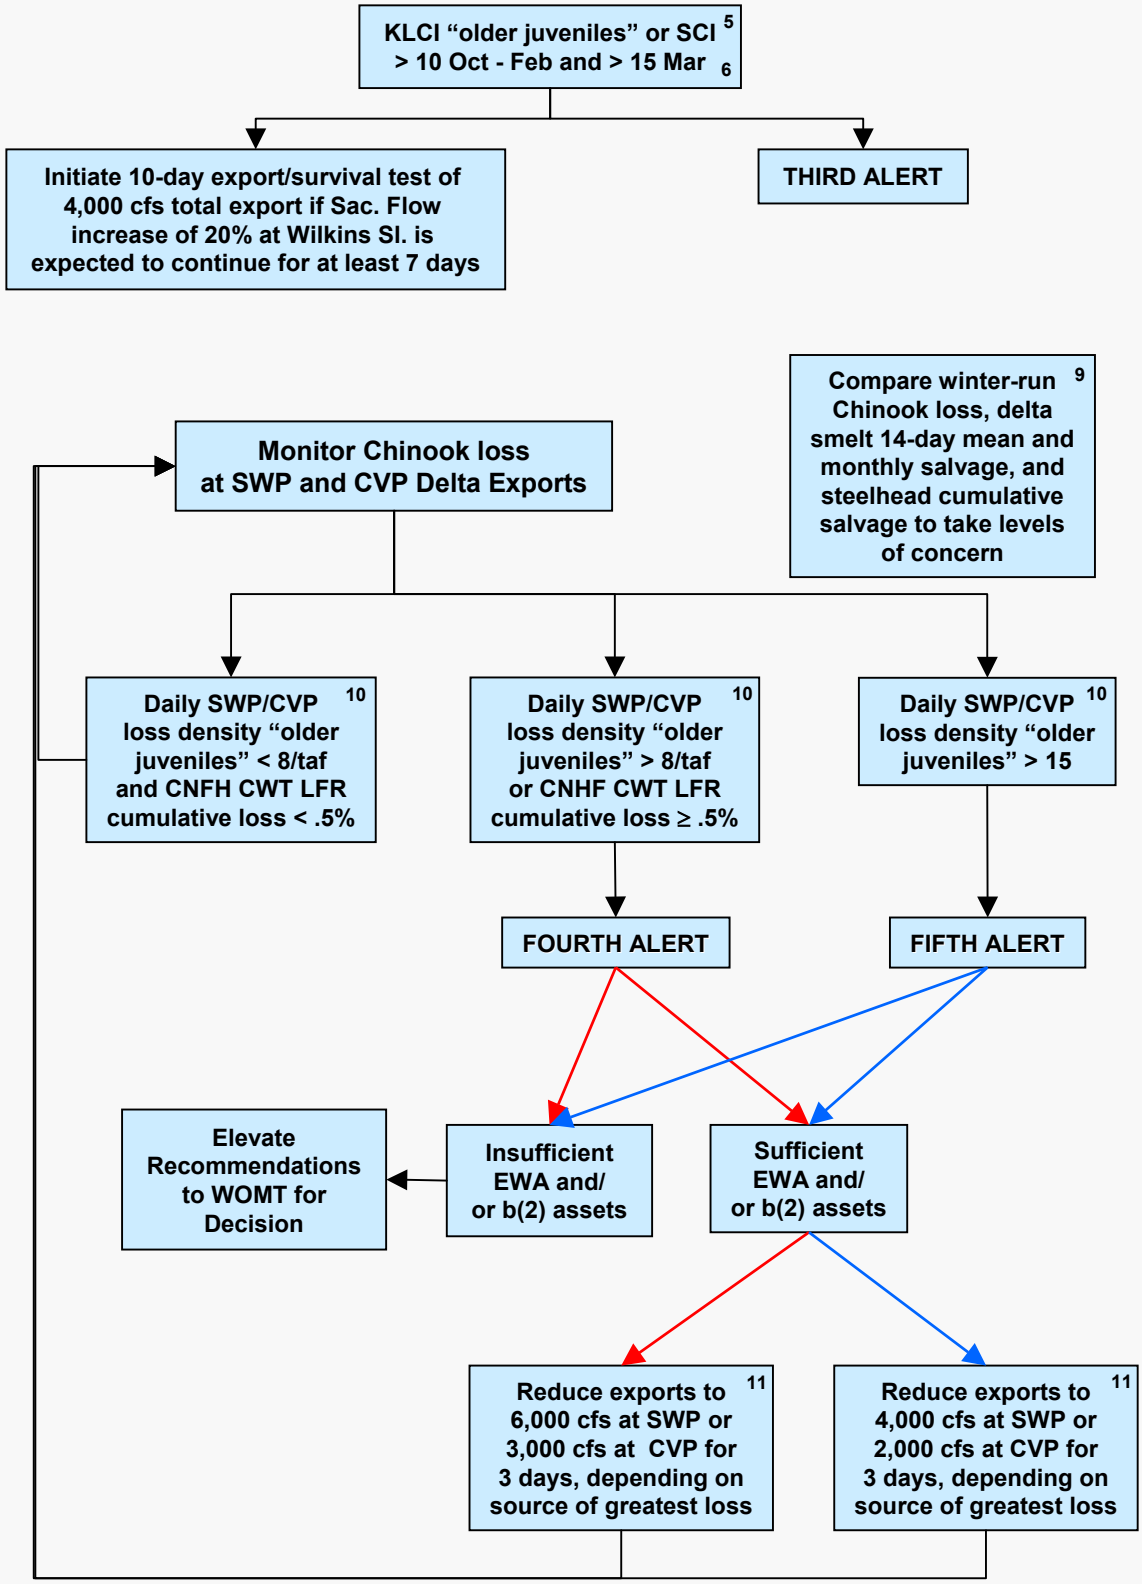


Table 2 The Delta Smelt Decision Tree (Continued)

Assessment of conditions (continued)	Timing: start and duration of spawning
	Implement model to predict future salvage (end of VAMP)
	Water quality conditions, water temperature
Tools for change	Change in San Joaquin River flows
	Change in export reductions (1–3 = net flow)
	Change in barrier operations
Biological questions using the available data	1) Is distribution of spawning broad or restricted?
	2) Is larval distribution broad or restricted?
	3) When does spawning start?
	4) Do we expect punctuated or protracted spawning?
	5) Do we expect SWP and CVP to reach red light salvage levels?
Questions concerning operations	Do we consider changing net flows in Old and Middle rivers?
Assessment of concern	I. If light trap results demonstrates that spawning has occurred in the south Delta, then concern is high
	II. If the 20-mm survey shows 50% of the delta smelt are in the zone of influence (e.g,. east of the confluence), then concern is high.
	III. If abundance in the 20-mm survey is low relative to other years, then concern is high.
	IV. If substantial larval recruitment is expected to occur in the south and central Delta post-VAMP, then concern is high
Recommendation	If concern is high and salvage is at or approaching red light or at yellow light, then recommendations to improve net flow in Old and Middle Rivers are likely. (This recommendation applies during VAMP and post-VAMP, although the tool used will vary.)
Life stage	Juveniles
Timing	Post-VAMP (May 15 through July 1)
Concerns	High numbers of delta smelt juveniles in the south and central Delta will likely result in increased entrainment when export levels increase at the end of VAMP
Data of interest	20-mm survey[b]
	Salvage
	Summer townet
	Hydrology (wet or dry year; placement of X2)
	Export rates
Assessment of conditions	Percent of the distribution outside the zone of influence (e.g., east and west of the confluence)
	Salvage level (number)
	Salvage density
Tools for change	Change in exports
	Change in agricultural barrier operations[d]
	Removal of HORB[d]
	Position of cross-channel gates
	Flow changes in San Joaquin, Old, and Middle rivers
Biological questions using the available data	1) What is the relative distribution in and outside the zone of influence (e.g. upstream and downstream of the confluence)?
	2) Is abundance high?
	3) Is salvage at or approaching red light or at yellow light?
	4) Are fish migrating west from the Delta?
Questions concerning operations	1) Do we consider changing exports?[e]
	2) Do we consider changing agricultural barrier/HORB operations?[e]
	3) Do we consider changing the position of the cross channel gates after May 20?
Assessment of concern	I. If the 20-mm survey shows 50% of the delta smelt are in the zone of influence (e.g. east of the confluence), then concern is high.
	II. If abundance in the 20-mm survey is low, relative to other years, then concern is high.
Recommendation	If concern is high and salvage is at or near red light, then recommendation for action is likely.

[a] Yellow light and red light as defined in the 1995 OCAP opinion.
[b] If fortnightly 20-mm survey is occurring and red light occurs, then effort will increase to weekly sampling.
[c] Salvage levels at this time will likely not reflect the number of delta smelt in the south Delta, since smelt begin to be counted at the salvage facilities at about 25 mm.
[d] The barriers shall be operated as stated in the USFWS biological opinion (1-1-96-F-53), April 26, 1996.
[e] Changes considered under "a" and "b" would aim to increase net positive flows in Old and Middle rivers downstream of the export facilities.

2003 EWA Acquisition Strategy

EWA Acquisition Strategy For 2003

I. Executive Summary

The Environmental Water Account (EWA) will enter its third year of operation in 2003. The Management Agencies and Project Agencies, which jointly administer the EWA, are developing a formal strategy for the acquisition of assets for the program for 2003. This paper sets forth the proposed strategy.

The EWA will begin 2003 with 68 TAF of carryover assets from 2002 acquisitions. Of the total, there is 57 TAF in relatively assured storage for cross-Delta transfer (20 TAF in Oroville Reservoir, subject to Delta carriage losses) and direct pump-out (37 TAF in Kern Water Bank). An additional 11 TAF is currently stored in San Luis Reservoir in anticipation of early-2003 fish actions. These in-hand assets will help offset budget challenges and the potential need for additional amounts of water to offset reductions in CVPIA Section 3406 (b)(2) assets originally anticipated under Tier 1.

The EWA Project Agencies will continue a strategy of acquiring maximum water supplies and related assets at minimum cost. To implement this strategy, the concept of functional equivalency, as established in the CALFED Record of Decision (ROD), will be applied to help the EWA reduce its costs.

The concept of functional equivalency as applied to water acquisitions would be applied by maximizing water purchases upstream of the Delta consistent with the Projects' capability to convey EWA water across the Delta prior to the low point in San Luis Reservoir. Options would be employed for the upstream purchases with spring call dates, and the amount of the lower cost upstream-of-Delta purchases would reflect the approximate cross-Delta transfer capacity.

The balance of the water assets would be acquired south of the Delta (in the export service areas). Source shift agreements totaling at least 100 TAF would be negotiated and activated only as needed in 2003. Other services, including storage capability and predelivery arrangements to protect EWA assets in San Luis Reservoir at year-end would be negotiated as the budget permits.

Water needs for 2003 are developed from assumed fish actions (pumping curtailments) that will be implemented by the EWA agencies. Placeholders of 230-450 TAF have been assumed for potential fish actions in 2003, depending on hydrology. These placeholders have been increased to help offset, at least partially, the perceived loss of Delta export reduction capability available to the Fishery Agencies due to recent federal court decisions. The fish actions would be supported by purchases (Table 1, below);

variable assets (about 50 TAF or more expected); activation of the source shift agreements (up to 100 TAF); and borrowing from the CVP and SWP, if required.

Table 1 summarizes the proposed 2003 EWA acquisition program. The purchased water component of the EWA (Total Delivery Goal in Table 1) is higher than that established in the CALFED Record of Decision (ROD) to help offset the perceived loss of Delta export reduction capability available to the Management Agencies due to recent federal court decisions. The 2003 total purchase targets in the table are adjusted downward to account for 20 TAF of EWA 2002 carryover water in Oroville Reservoir and 37 TAF of EWA 2002 water in Kern Water Bank storage, which together will provide 53 TAF of available assets, adjusted for Delta carriage losses. Both quantities, plus an additional 11 TAF in San Luis, are available for 2003 fish actions.

Table 1
Summary of EWA 2003 Purchase Goals

Year Type	Approximate SWP Allocation	Total Delivery Goal[(1)]	UOD Pumped X-Delta	Usual UOD Purchases	Usual SOD Purchases	Minus Carryover From 2002	Total 2003 Purchase Target
Dry and Critical	< 50%	210	210	260	0	52	200
Below Normal	50-75%	240	115	145	125	52	215
Above Normal	75-90%	240	60	75	180	52	200
Wet	90-100%	240	60	75	180	52	200

(1) Goal for delivering purchased water assets to the projects to compensate for operational curtailments.

In addition to acquisitions, it is estimated that the EWA can rely on approximately 50 TAF of water under the Variable Assets provided in the ROD. The EWA may be able to gain additional variable assets in wetter years if San Luis Reservoir fills and spills EWA water debts, assuming relatively aggressive management of such debt. Also, the availability of additional capacity included in the ROD as part of the Variable Assets would be used to benefit the EWA.

The EWA Agencies would continue to coordinate acquisition activities with the USBR water acquisition programs for (b)(3) uses, instream purchases, and refuges. The program would also continue to be integrated with the DWR Dry Year Program and begin coordination with the Colorado River Contingency Program and Drought Risk Reduction Investment Program.

The EWA Agencies will use source-shifting arrangements to carry EWA debt above the delivery goals into the following year if it is needed. This 100 TAF of debt carryover capability is an important aspect of achieving the EWA flexibility envisioned in the

CALFED ROD because it can increase asset availability in some years and increase the potential for debt erasure in very wet years after San Luis Reservoir fills.

In 2003, the EWA will begin to work on longer-term agreements for assets and services as the EIS/EIR is completed. Longer-term arrangements are anticipated to provide the EWA with greater certainty, lower long-term costs, and enhanced flexibility and reliability.

The EWA is interested in diversifying its sources of assets to lessen its impact on the water market; provide opportunities for using multiple sources; minimize cost; coordinate with other transfer programs, including refuge programs; and maximize the effectiveness of CALFED Program investments. This diversification includes both SWP and CVP sources of replacement water south of the Delta. The EWA in 2002 made reductions in exports at both the CVP and SWP export facilities and will do so in the future. Partnerships between EWA and both CVP and SWP users south of the Delta ease the administrative tasks of replacing these water supplies for each project, respectively.

II. Introduction

The Environmental Water Account (EWA) is a cooperative management program whose purpose is to provide protection to the fish of the Bay/Delta Estuary through environmentally beneficial changes in the operations of the Central Valley Project (CVP) and the State Water Project (SWP) at no uncompensated water cost to the CVP and SWP project users. The EWA is a key component of CALFED's Water Management Strategy, funded through State and federal public funds to address declining fish populations and unreliable water supplies.

The EWA, when taken together with the other aspects of the CALFED Bay/Delta Program, provides part of the resources required for the protection and recovery of critical fish species of the Bay Delta Estuary and provides assurances that the water supplies of the CVP and SWP will not be reduced to provide that protection.

The Management Agencies, which are the U.S. Fish and Wildlife Service, the National Marine Fisheries Service, and the California Department of Fish and Game; and the Project Agencies, which are the U.S. Bureau of Reclamation and the California Department of Water Resources are jointly responsible for implementation of EWA. This document focuses on the acquisition of the EWA assets necessary to achieve its purpose and objectives.

III. Asset Acquisition Strategy: Goals and Objectives

This section of the document sets forth the proposed goals and objectives for the acquisition of assets for the EWA in 2003. It is intended as an overview of the

framework for the EWA acquisition program for 2003 and future years. It provides information on how the program expects to mature and develop long-term stability. Pursuit of some of these goals must await completion of the long-term EIS/EIR on the EWA Program. Implementation of other goals may require additional CEQA and NEPA coverage, including separate CEQA and NEPA actions by The Project Agencies, although the planning activities necessary to bring the goals forward to a decision may be initiated in the coming year. The asset acquisition program strategy for 2003 incorporates the following goals and objectives:

- Define the purchase strategy
  - Define clearly the placeholders necessary to meet the EWA's needs
  - Define clearly the asset purchase targets for 2003 by fall 2002 in conjunction with estimated needs for future years
  - Define clearly the concept of functional equivalency for EWA assets and adjust purchase targets appropriately
  - Identify participants, constraints, opportunities, and funding needs and sources
  - Define clearly the asset management strategy for various potential operational scenarios

- Acquire water at the most effective unit cost
  - Approach prospective sellers with clearly defined needs and clear understanding of adjusted targets that reflect functional equivalency
  - Purchase upstream-of-Delta water to the extent cross-Delta conveyance is assured in any hydrology
  - Negotiate options for additional amounts of lower-cost upstream-of-Delta water that can be exercised when additional cross-Delta conveyance is available in drier years
  - Negotiate SWP allocation triggers into south of the Delta (export service areas) purchases to provide the required balance of EWA assets when the EWA's cross-Delta transfer capacity is constrained in wet years
  - Coordinate the option and purchase agreements to maximize upstream-of-Delta purchases when Delta conveyance capacity will be available (in drier years), supplementing with south of the Delta purchases only to the degree necessary when transfer capacity is restricted, with decision dates late enough to assure meeting asset acquisition targets
  - Negotiate 2003 asset purchases in the fall of 2002 and executing contracts before 2002-2003 hydrology can become an issue
  - Structure agreements over longer terms, subject to funding commitment constraints and environmental coverage, to lock in pricing and simplify future negotiations
  - Negotiate a flexible option agreement for the source shift and exercise only when needed
  - Continue to pursue actively all opportunities to acquire variable assets

- Expand the asset base
  - Prepare and distribute formal notification of anticipated water needs to a larger audience of EWA interests
  - Request additional funding or modifications to “encumbrance” requirements to pursue more option agreements, and increase the ability to have numerous options without encumbering funds until required
  - Initiate negotiations with additional agencies to increase the competition for inclusion as a seller to the EWA program
  - Pursue acquisitions that can also provide flow increases, temperature modification, and other beneficial actions

- Improve flexibility
  - Pursue longer-term arrangements as soon as the EIS/EIR is completed and a decision is made regarding the future of the EWA Program beyond the four-year initial phase
  - Pursue the planning activities leading to an approval for the direct purchase of SWP and CVP entitlement water that would otherwise be put to beneficial use by the contracting agency, including carryover water, recognizing that additional CEQA and NEPA documentation will be required
  - Pursue participation in SWP programs such as Turn-Back Pools, recognizing that this will require SWP CEQA action
  - Negotiate purchases in both CVP and SWP service areas
  - Make the negotiation and contracting process as smooth and swift as possible
  - Increase borrowing from the SWP and CVP when prudent and appropriate

- Protect assets
  - Negotiate groundwater banking arrangements and south-of-Delta storage agreements, including pre-delivery and short term carryover, to protect EWA assets
  - Negotiate carryover clauses where appropriate to allow an asset to remain in place and be transferred in a future year

- Continue coordination with other water purchase programs
  - Coordinate with CVPIA Level 4 refuge purchases and in-stream flow purchases to ensure the priority accomplishment of both each year
  - Coordinate purchases for the EWA and dry year programs to mitigate competition between the programs and allow shifting of assets as needed
  - Coordinate purchases with other CALFED water purchase programs

- Maximize the effectiveness of CALFED Program investments
  - Enhance water bond grant selection criteria to encourage infrastructure that will support future EWA success
  - Propose EWA participation as potential partner with other applicants (combine existing funds with grant funding)

- o Propose EWA as independent applicant (enhance purchasing power of existing funds with additional grant funds)

IV. Supporting Analysis for the EWA Acquisition Strategy

This section provides the supporting analysis to define the rationale behind the acquisition strategy and provide background information on the EWA. A summary of 2001 and 2002 operations is presented in Section VI.

A. EWA Context

The EWA operates within the water right permits and operational aspects of the SWP and CVP. This special arrangement and the EWA's purchased and variable assets are specifically set forth in the EWA Operating Principles and the CALFED ROD signed by, among others, the Secretary of Interior and the Director of Water Resources who oversee the operation of these projects.

Even with EWA, the CVP and SWP continue to be operated fully within the constraints defined by D-1641, the applicable biological opinions, and all other regulatory requirements. Although an independent CALFED program, the EWA can be viewed as the reoperation of the CVP and SWP to provide protection and enhancement to sensitive fish species of the Bay/Delta estuary. As explicitly provided in the ROD, the SWP and CVP use their water rights as necessary to acquire EWA assets. These assets are to be stored and delivered through the SWP and CVP facilities. The ROD specifically allows EWA assets to be stored in project reservoirs to the extent that space is available, even though such services are unavailable to non-project entities. These provisions provide a special status to the EWA.

Currently, EWA water that is stored in facilities of the CVP and SWP is considered Project water with an EWA label. It cannot be viewed or treated in the same manner as water held by third parties that requires the use of project facilities or other project use benefits. Normal fees do not apply as they would to other third party users nor do third party users have free access to the operational flexibility afforded to the management of EWA assets. However, the EWA is subject to power and facility costs for the use of these facilities.

No CVP or SWP contractor or independent third party has this flexibility. External users cannot use the aspects of this strategy, the EWA Operating Principles, or the 2003 Interim Protocols for the Operation of the EWA as precedent for treatment similar to that of EWA.

Both SWP and CVP contractors and the environment benefit from the operation of EWA. A fully functional EWA provides commitments that there will be no additional reductions in project deliveries relative to the regulatory baseline as a result of the

needs to recover critical fish species. The water supply reliability afforded by EWA should be considered in overall costs for using such facilities. In addition, the contractors benefiting from such reliability should consider these benefits in their water supply and service arrangements with the EWA and should offer the EWA market arrangements that reflect the multiple benefits they receive.

Over the next year and a half several actions will affect the future direction of the EWA. These actions include:

- The review of the EWA prior to its scheduled expiration on September 30, 2004 as required in the CALFED Record of Decision (ROD);
- Expansion of permitted pumping capacity at the Banks Delta pumping plant from 6,680 cfs to 8,500 cfs;
- Availability of additional water to the projects due to the pending water right settlement of Phase 8 of the SWRCB's water right proceedings;
- Determination by the Department of Interior of its new policy for the appropriate accounting for CVPIA 3406 (b)(2) expenditures for fishery protection as directed by the courts;
- Completion of the EWA EIR/EIS in 2003
- Increased cross-Delta transfer activity related to Colorado River supply issues

B. EWA Strategy: Tie Water Purchases to Hydrologic Conditions to Minimize Costs

The CALFED Record of Decision establishes EWA purchased asset targets at 185 TAF with 35 TAF coming from sources upstream of the Delta and 150 TAF coming from sources south of the Delta or the functional equivalent of these assets. In contrast, there is more water available for transfer from areas upstream of the Delta, and at a lower cost, than from areas south of the Delta. Strict adherence to the 35/150 TAF ROD requirements has the potential to place an avoidable cost burden on the EWA. The EWA has taken advantage of the functional equivalence criteria to purchase a greater portion of the water from upstream sources and thereby acquire the purchased assets within the limitations of available EWA funding.

The amount of water available for transfer is typically greater from areas upstream of the Delta than areas south of the Delta, especially in dry years. This difference is reflected in the market rates received by willing sellers in these two areas. The differences in water prices upstream and south of the Delta are greater than simply the costs of transporting water across the delta. The differences reflect a structural difference in the water economies of these two areas.

One reason for the higher south-of-Delta cost is that the EWA's 2001 and 2002 water purchases in SWP service areas south of the Delta have been restricted to the relatively limited supply of previously banked groundwater. Banked groundwater has been purchased, transported, banked, and must then be pumped out to be delivered, and is

therefore more expensive than upstream sources. In addition, water prices south of the Delta reflect an economy that depends in a substantial part on water supplies imported into the region. These imported water supplies are more expensive than locally developed water supplies.

Initial EWA water purchases during 2001, the first year of operation, followed the general split of EWA purchases established in the CALFED ROD, although upstream-of-Delta purchases exceeded 35 TAF. However, in 2002 water purchases from upstream of Delta sources were increased beyond that established in the CALFED ROD to reduce the amount of south of the Delta purchases. The purchases provided the "functional equivalent" of the 150 TAF of EWA assets south of the Delta to offset EWA export reductions.

The EWA can become much more efficient and minimize its costs if it expands the concept of functional equivalency referenced in the ROD. The concept can be effectively applied to a water purchase strategy that maximizes water purchases upstream of the Delta consistent with the Project's capability to convey EWA water across the Delta. Water supplies need to be acquired and moved across the Delta prior to the low point in San Luis Reservoir, which typically occurs in August or September.

From a financial point of view EWA purchases should be focused on upstream of Delta areas to minimize costs. However, the EWA does not have secure pumping capacity available to convey all its water supply purchases across the Delta in all hydrologic conditions. Therefore, the EWA should pursue a strategy where it maximizes upstream of Delta purchases to the extent that it can convey water across the Delta.

Table 2 shows the cross-Delta conveyance capacity that the EWA Team will use to develop its water purchase and management strategy for 2003. The available capacity estimates include the 500 cfs summer capacity dedicated to the EWA. The EWA priority for pumping is set forth in the ROD and detailed in the 2003 Interim Protocols for the Operation of the EWA. An unknown factor is the extent that other SWP contractor water transfers will affect the EWA's access to SWP conveyance. An assumption has been made regarding the volume of SWP contractor transfers with a priority higher than the EWA that are likely in various SWP allocations based on recent experience.

If the amount of water being transferred for SWP contractors from upstream of the Delta increases, then the SWP's capacity to convey EWA water will decrease. In addition, the conveyance of the Phase 8 settlement water supplies for SWP contractors will also decrease the SWP's conveyance capacity for EWA water. Table 2 reflects these estimated Phase 8 settlement supplies in 2003 (50 TAF) and will be adjusted each year to reflect the best projection of the SWP's capacity to convey EWA water.

Table 2 shows that the EWA's capability to convey water through the SWP facilities decreases in normal and wet years, and is least when SWP allocations are 75% of requests and above. A marked transition occurs in dry to below normal years (SWP allocations between 35% and 70%). The EWA agencies will purchase water upstream

of the Delta consistent with this table up to the amount deemed necessary, allowing for carriage water losses.

Since it cannot be projected with certainty what the projected SWP allocation will be when contracts are negotiated, EWA contracts will use options for part of the purchases upstream of the Delta or contract provisions tied to SWP allocations to accommodate uncertainty over conveyance capacity. Water purchases south of the Delta can be tied directly to SWP allocations in many instances.

Table 2
Anticipated EWA Cross Delta Conveyance as a Function Of SWP Allocations in 2003

SWP Annual Allocation Percentage	EWA Cross-Delta Capacity TAF [(1)]
100	60
95	60
90	60
85	60
80	60
75	60
70	60
65	99
60	138
55	190
50	242
45	330
40	418
35	459
30	500
25	501
20	503

(1) Capacity computations assume use of the EWA's 500 cfs capacity in wetter years. Additional capacity becomes available in drier years, reduced by a modest Dry Year Water Acquisition Program and assumed SWP contractor transfers of 200 TAF

C. Coordination of EWA With CVPIA Section 3406 (b)(2) Assets

CVPIA Section 3406 (b)(2) provides that 800 TAF of CVP yield be dedicated to fishery benefits. The USBR has been operating the (b)(2) program for several years, and the Project Agencies have been coordinating its operation with the EWA. However, recent court decisions have found that the accounting mechanisms used to calculate (b)(2) expenditures needed modification. The court has ordered that new accounting methods be employed.

A new (b)(2) policy is under development and is expected to be completed in early 2003. This new policy will reflect the findings of the court and is expected to result in less flexibility for the use of (b)(2) assets and fewer fish actions. The potential for there to be less (b)(2) water available for use in the Delta was addressed last year by increasing EWA water purchases to partially offset the perceived reduction in the (b)(2) baseline.

Regardless of the policy decision on whether to offset (b)(2) losses with EWA assets, the EWA will continue to be coordinated with (b)(2). It will be critical to continue to coordinate the management of EWA assets with (b)(2) actions, as those actions will affect EWA water purchase needs and use of EWA funds. The EWA "gaming" that has been done for the EWA assumes that the two programs would be coordinated.

The EWA agencies will need to make a policy decision in 2003 on the extent that the EWA can and should be used to help offset the perceived losses of (b)(2) assets. This offset may require some EWA expenditures for in-stream actions upstream of the Delta.

In the past two years EWA assets have been used in limited ways upstream of the Delta. Actions have included bypassing the power plant with a portion of Folsom Reservoir releases in the late fall to draw upon the cold water pool deep in the reservoir. The cold releases help achieve improved temperature conditions for salmon spawning and outmigrating steelhead in the Lower American River. This action used EWA power credits; no EWA water was used. On the Yuba and Merced Rivers, releases of EWA assets were scheduled to support instream fishery benefits of the EWA water transfer.

The EWA budget is currently reserving about $1 million for federal power purposes. Some of this money may be used to purchase power lost by the Folsom bypass next fall and some may be used to offset the costs associated with pumping EWA water in the Delta in the summer to replace water forgone earlier at the Delta export facilities when those costs are greater than the power savings from the reduced pumping in the spring.

D. Continued Coordination of EWA Water Acquisitions with DWR Dry Year Program, USBR CVPIA Level 4 Wildlife Purchases and Instream Flow Purchases, and Other CALFED Water Purchase Programs

One of the major challenges of the EWA is to coordinate its water purchase actions with those of other CALFED programs. In 2002, DWR agreed to coordinate water purchases for the State's Dry Year Program with the EWA purchases. In extremely dry years, EWA water purchase needs will decrease while the needs of water users will likely increase. These somewhat offsetting demands and the general benefit that the EWA provides to all the contractors of both the SWP and CVP argue for this continued coordination. Where there is conflict between these two programs, EWA purchase needs should take priority so as to not jeopardize ESA commitments. However, conveyance of dry year water for SWP contractors takes priority over EWA conveyance under the established protocols.

The CVPIA also purchases water for instream uses for both the Vernalis Adaptive Management Program (VAMP) and for Level 4 wildlife refuge supplies. The VAMP needs do not compete with or conflict with the EWA. Also, most of the refuge supply needs occur in the fall at a time that that does not directly conflict with the EWA's need for export capacity. There may be opportunities for mutual benefits among these programs.

As discussed below, federal partners south of the Delta could be beneficial to the EWA. CVP contractors south of the Delta who have in the past partnered only with the refuge program have expressed some interest in selling water to the EWA. In 2002, actions have already begun to coordinate the refuge purchases with those of the EWA. Due to the offset in timing of needs and variable funding for the CVPIA refuge program, both programs could benefit from joint purchase contracts. The EWA would benefit by having additional markets south of the Delta to purchase water. The coordinated use of water between these two programs would be resolved during the contract process in a manner acceptable to both programs.

Other water purchase programs by CALFED agencies include the EWP, CVP's coordination of dry year purchases by its contractors, the Drought Risk Reduction Investment Program (DRIPP) currently under development by DWR, and the purchase of water made available by the Phase 8 water right settlement process. The EWP program is charged with purchasing up to 100 TAF of water per year to improve salmon spawning and juvenile survival in tributary streams upstream of the Delta by the end of CALFED Stage 1. Some of the ERP flows may contribute to EWA. The ERP does not currently target streams that would conflict with EWA purchases. However, as the EWP program develops there may be opportunities for joint EWP/EWA purchases where water is purchased specifically for upstream actions that will also augment Delta supplies at a time valuable to the EWA.

The DRIPP would only initiate water purchases in the event a drought occurs and buyers request supplemental supplies. Purchases will be made to satisfy those orders for water only. These purchases are likely to be initiated long after the EWA has identified its supply sources and negotiated purchase contracts. The coordination of this developing program with the EWA has not yet been addressed, and coordination will depend on how and when the water purchase aspects of the program are implemented.

The coordination of the Phase 8 settlement water purchases may take the form of joint contracts where part of the water will be made available for SWP and CVP contractors and if extra water supplies exist, water could be made available for the EWA and DWR's Dry Year Program. The price provisions of the Phase 8 water have already been negotiated and will likely be different from the market rates at which the EWA and the Dry Year Program will be able to purchase water.

E. EWA Acquisition Strategy: The Need to Set Water Purchase Targets

The CALFED Record of Decision establishes annual EWA water acquisition targets of at least 185 TAF. The EWA Team has interpreted the concept of functional equivalent as the ability to deliver an equal quantity of water south of the Delta to that which was used to protect fish at the time of an operational curtailment. Under this interpretation, EWA purchases of water upstream of the Delta need to include allowance for additional water to offset the carriage water and other system losses that are experienced moving this water to the pumping facilities in the Southern Delta. Conveyance losses in the San Joaquin River and its tributaries are estimated at 10%, while carriage water losses in the Sacramento River and its tributaries are estimated at 20% for planning purposes. Actual Delta carriage losses in 2001 were 15%, and in 2002 were 20%.

The EWA proposes to use this functional equivalent concept as a key aspect of its strategy to maximize upstream of Delta purchases consistent with cross-Delta conveyance capacity.

As discussed earlier, the flexibility to use (b)(2) assets in the Delta as part of the baseline level of protection was modified by the courts. A policy decision needed for 2003 is the extent the EWA water purchase targets should be increased above the 185 TAF to account for the changes in (b)(2) assets. The EWA purchased water in excess of the 185 TAF in 2002 that was used to support a CVP operational curtailment at a time when (b)(2) assets were exhausted (Section VI summarizes 2001 and 2002 EWA operations). Purchase targets are higher than the 185 TAF established in the ROD to help support similar actions in 2003 and to ensure that the EWA can provide the assets required to meet operational needs considering carriage losses and other variables.

Based on the use of this EWA purchase strategy, the EWA's expected budget, the prices for water and services that may be possible for the EWA in 2003, and the gaming

that has recently been completed, the recommended EWA delivery targets for purchased assets would increase from 185 TAF to 210 TAF in dry and critical years and 240 TAF in below normal and wetter years. This increase of EWA purchased assets should ensure that the ROD commitments are achieved and continue the trajectory toward recovery for fish species of the Bay/Delta estuary.

F. EWA Acquisition Strategy: Purchase Partners

The EWA needs to broaden its base of potential partners from which to purchase water. For the EWA to be an effective partner, it needs to understand the needs of the sellers, develop a clear understanding of the types of water it wishes to purchase, and communicate the conditions that will apply to transfers that require the use of project facilities to complete.

In 2002, the DWR developed a set of water transfer papers that explain current water transfer laws and the DWR's compliance with these laws related to the purchase of water for the EWA and other programs. These papers provide water sellers a set of tools they can use to develop mitigation measures that protect other legal users of water and fish and wildlife as they develop their water transfer proposals. These papers can be found at: http//www.watertransfers.water.ca.gov.

In addition, DWR and USBR will work with prospective sellers on issues related to compliance with CEQA and NEPA and the State and federal endangered species acts.

G. EWA Water Purchases Upstream of the Delta

As discussed above, water purchases upstream of the Delta are typically less expensive to the EWA that those south of the Delta. Table 2 shows the expected EWA cross-Delta capacity to move water from upstream to south of the Delta in the summer months. The EWA should maximize its purchases upstream of the Delta to the extent it needs the water and can effectively move this water through the Delta. The EWA could base these contracts on SWP capacity to convey this water for the EWA under its pumping priority. However, upstream of Delta sellers may be reluctant to base purchases on these allocations. If this proves to be the case the EWA could set up options to purchase water, as it has in the last two years. A small non-refundable option payment would be made and dates set for the call of the option. Once called, the water would be delivered and the strike price (remainder of payment) made to the seller.

Upstream-of-Delta purchase targets are determined by using the cross-Delta transfer capacity values in Table 2, allowing for 20% carriage losses. For SWP allocations of 65-100%, for example, the EWA would purchase 75 TAF and transfer 60 TAF, with 15 TAF comprising the carriage losses. The EWA would plan to purchase 75 TAF in all year types. As SWP allocations decrease below 60%, upstream-of-Delta options would be exercised to increase upstream-of-Delta purchases up to the expected cross-Delta

transfer capacity or the annual purchase target, whichever governs, allowing for the carriage losses.

Aggressive use of options upstream of the Delta would provide the EWA flexibility to deal with changing hydrologic conditions. One concern related to options is that in many cases the call dates needed by the sellers occur early in the year before much is known about the hydrologic conditions. The EWA will seek option call dates as late into the year as possible consistent with the needs of the sellers.

The EWA would take a small risk of stranding water upstream of the Delta if, after exercising its options, there are late storms and hydrology improves, and the EWA loses some of its projected transfer capacity. This situation could leave assets stranded upstream and subject to loss. The risk can be minimized with options that can be exercised late in the spring after the chance of significant additional rainfall is minimal. Also the EWA will likely not call on all the options if the year turns wet. Thus in some years the small option fee will be paid on water than will not be delivered from some contracts. These options are similar to insurance costs, and are part of the cost of obtaining lower cost water overall.

1. Transfer Types Upstream of the Delta

There are three basic ways in which water can be made available for transfer: from previously stored flows, through use of alternative supplies that would not otherwise be used, and from reductions in use. In any case, it must be demonstrated that the water is being made available from a legitimate alternative source and that there is no unreasonable harm to fish and wildlife.

Certain types of water transfers are easier to implement and manage than others, and are preferable to the EWA. Experience has shown that transfers of previously stored flows are the most flexible. If a willing seller owns a storage reservoir, they often have the flexibility to manage their facilities to make water available from supplies excess to their needs. To complete the transfer, they must demonstrate how they intend to make the water available, agree to a release pattern that at a minimum causes no harm to fish and wildlife resources, and enter into a re-fill agreement to prevent harm to other legal users of water.

Where applicable, option call dates are often in late spring, which provides the seller a better idea of the amount of water available to transfer. Reservoir storage transfers work to the EWA's advantage because the later call dates allow the scheduling of the releases with greater certainty that the EWA will have access to transport capacity in the Delta.

Groundwater substitution transfers are the next type of transfer used by the EWA. Such transfers involve the substitution of groundwater supplies for surface water diversions. The greatest flexibility is offered by willing sellers that have

flexibility to hold their surface diversions in an upstream reservoir for later release to the EWA. When this is not possible, the groundwater substitution pattern must coincide with the availability of export capacity in the Delta. Groundwater substitution transfers require a demonstration that the wells being used are not pumping surface water and if the transfer requires the use of Project facilities, monitoring and mitigation programs must be in place (see DWR's water transfer papers).

The third and least flexible type of transfer involves the idling of cropland to make water available for transfer. Crop idling transfers have been done historically in the Sacramento Valley in extremely dry years. The volume of water available for transfer is limited to that quantity that would have otherwise been consumed or lost to a saline sink. In locations where water deliveries are made directly from a reservoir to the water users (like the Feather River contractors) water not used for irrigation can be held in storage and released for the EWA at a time when it can moved through the Delta and exported with less impact on fish of the Delta.

However, in cases where the willing seller has direct diversion rights from a river, forgone consumptive use in April, May, and parts of June may not be effectively captured and exported by the Projects for the EWA. For this water to be captured, the Projects must have the capacity to convey water for the EWA when it is made available, or the Projects must have the ability to back these supplies into a CVP or SWP upstream storage reservoir. The increased flow due to the decrease in river depletions may not be able to be captured by the Projects for the EWA in the Delta due to export restrictions to protect fish at the Delta pumping plants during these months.

Backing the water into upstream reservoirs is rarely possible because of operational constraints or flow, temperature, or other regulatory requirements downstream from the reservoirs. Therefore, only the water supply that can be effectively captured by the Projects for the EWA as a result of idling accrues during part of June, July, and August, even though irrigators have not planted crops earlier in the year. Because the EWA could not capture the full amount of water potentially made available, the net costs could make this water more expensive and less desirable than other types for the EWA to purchase. In addition, the decision to exercise options for crop idling transfers must be made very early in the year (around February) to provide farmers enough time to plant crops if the option is not called. Crop idling transfers will likely only be used in extremely dry years for those areas not served directly from reservoirs.

2. Upstream of Delta Transfer Sources

Potential EWA partners for upstream of the Delta transfers include:

Yuba-Feather River

- Yuba County Water Agency (YCWA): Reservoir storage
- Member agencies of YCWA: Groundwater substitution with re-regulation by YCWA
- Browns Valley Irrigation District: Reservoir storage from Collins Lake and groundwater substitution with re-regulation by YCWA
- Oroville-Wyandotte Irrigation District: Reservoir storage
- Western Canal Water District: Crop substitution, crop idling
- Joint Water District Board: Crop substitution, crop idling

Sacramento River

- Glenn-Colusa Irrigation District, RD 108 and other sellers to the 2001 forbearance agreement: Groundwater substitution, crop idling

American River

- Placer County Water Agency: Reservoir releases
- Sacramento Groundwater Authority: Sale of banked groundwater by exchange, groundwater banking services

San Joaquin River

- Merced Irrigation District: Groundwater substitution with reservoir re-regulation, crop idling
- Other east side San Joaquin Reservoirs (specifics to be provided by EWA Team

H. EWA Water Purchases South of the Delta

The amount of water needed from areas south of the Delta increases in normal and wet years and is less in dry years when there is capacity available to move water from areas upstream of the Delta. The amount of water needed south of the Delta can be

determined by subtracting the upstream-of-Delta deliveries from the delivery target. The remainder is the south-of-Delta purchases. Table 1 provides a general illustration of this calculation for the proposed 2003 water purchases. Table 3 provides greater detail of the estimate of south-of-Delta purchases for 2003, based on cross-Delta transfer capacity available to the EWA in 2003. These capacity estimates assume a modest DWR Dry Year Water Purchase Program and cross-Delta transfers by SWP contractors of up to 200 TAF using their conveyance priority.

Table 3
Estimated South-of-Delta Water Purchases for 2003

SWP Allocation	Approximate Quantity, AF
50%	5,000
55%	30,000
60%	120,000
65%	145,000
70%	145,000
75%	145,000
80-100%	145,000

South-of-Delta purchases in the SWP service area can be tied directly to SWP allocations as was done in 2002 in the Kern County Water Agency contract. This provision has an advantage because the price of the water often decreases with the increase in the SWP allocation. Therefore, as the need for water for the EWA increases the price per acre-foot decreases. Contracts can be written to reflect this dynamic if the quantity and price are both tied to SWP allocations. If the contractor is a CVP contractor the same types of contracts might be possible.

South-of-Delta purchases will be sought from willing sellers in both the SWP and CVP service areas. It is administratively easier and often locally preferable to repay reductions in exports with water that was purchased from the respective service areas of these two projects. In dry years this is not so critical but in normal and wet years when most purchases are forced to be south of the Delta, a realistic split of purchases in these two service areas is desirable. In 2002 and in the future the EWA will take export reductions at both the CVP and SWP export facilities in the Delta. In 2002 the split of export reductions between the CVP and SWP was about 1/3 CVP to 2/3 SWP. This preliminary ratio will be used as a guide in conjunction with projected placeholders developed through coordination with implementation of (b)(2) in developing contracts for south of the Delta between water users in these two service areas in 2003.

1. Transfer Types South of the Delta

To date the EWA has pursued only the purchase of previously banked groundwater south of the Delta for the EWA from south of Delta sources. It is possible that the EWA will pursue crop idling transfers in this region, if environmental impacts and other issues can be successfully resolved.

Due to contract language in the SWP Long Term Water Supply Contracts, only previously banked groundwater or water that would otherwise be banked can be sold to others. This restriction limits the EWA's capability to purchase water south of the Delta. As explained above, south of Delta banked groundwater is more expensive than upstream of Delta purchases. In addition, there is a limited quantity of banked groundwater that can be purchased.

DWR staff is working with its contractors to determine ways this limitation might be resolved in the future. To the extent that the EWA purchases previously banked groundwater south of the Delta, negotiating a provision that allows the EWA to maintain this water in the bank for another year or more if it is not needed as initially anticipated would provide needed flexibility. Prior experience indicates that negotiating these terms can be complicated and would have an associated cost. However, this cost needs to be balanced against the potential consequences of extracting the water and then needing to protect it from loss if it is not needed for a fish action before San Luis Reservoir fills and this water is displaced.

2. South of Delta Transfer Sources

Potential partners in areas south of the Delta include:

East Bay Region

- Santa Clara Valley Water District (SCVWD): Local storage to provide flexibility for EWA: pre-delivery; source-shifting (deferred delivery); groundwater banking services (Semitropic Water Service District banking program); sale of CVP contract supply in wet periods

San Joaquin Valley

- SWP contractors including: Kern County Water Agency (KCWA), its member agencies, and regional banking agencies, including Semitropic Water Service District, Cawelo Water District, Tulare Irrigation District, Rosedale-Rio Bravo, Westside Mutual Water

Company, Tejon-Castac, Dudley Ridge: Sale of banked groundwater, by exchange or direct pump-in to aqueduct; groundwater banking services; surface water destined for recharge, by exchange; crop substitution, fallowing

- CVP contractors including users in the San Luis Unit, San Joaquin River exchange contractors and Cross Valley contractors

- Other San Joaquin Valley agencies: groundwater banking services; surface water destined for recharge, by exchange; crop substitution, fallowing

- Other agencies outside of the San Joaquin Valley that bank in the San Joaquin Valley, including SCVWD, Metropolitan Water District of Southern California (MWDSC), Mojave Water Agency

- Friant interests: Surface water by exchange

Southern California

- Mojave Water Agency: Sale of banked groundwater, by exchange; groundwater banking services

I. Variable Assets and Tools Needed
