Suisun Marsh
Habitat Management, Preservation, and Restoration Plan

May 2013
Executive Summary

The Suisun Marsh Habitat Management, Preservation, and Restoration Plan, referred to from here on as the Suisun Marsh Plan (SMP), is being pursued by the Suisun Principal Agencies (or Principals), a group of agencies with primary responsibility for Suisun Marsh management, and is intended to balance the benefits of tidal wetland restoration with other habitat uses in the Marsh by evaluating alternatives that provide a politically acceptable change in Marsh-wide land uses, such as salt marsh harvest mouse habitat, managed wetlands, public use, and upland habitat. It relies on the incorporation of existing science and information developed through adaptive management. The Principals are U.S. Fish and Wildlife Service (USFWS), U.S. Department of the Interior, Bureau of Reclamation (Reclamation), California Department of Fish and Game (DFG), California Department of Water Resources (DWR), National Marine Fisheries Service (NMFS), Suisun Resource Conservation District (SRCD), and CALFED Bay-Delta Program (CALFED). The Principals have consulted with other participating agencies, such as the U.S. Army Corps of Engineers (Corps), San Francisco Bay Conservation and Development Commission (BCDC) the Regional Water Quality Control Board (RWQCB) and the State Water Resources Control Board (State Water Board), in developing this plan.

The SMP is intended to address the full range of issues in the Marsh, which are linked geographically, ecologically, and ideologically. Many of these issues have been recognized in other planning documents such CALFED Record of Decision (ROD), and the Revised Suisun Marsh Preservation Agreement. The SMP incorporates these plans and directives, while meeting the following plan objectives.

- **Habitats and Ecological Processes**—implement the CALFED Ecosystem Restoration Program Plan (ERPP) restoration target for the Suisun Marsh ecoregion of 5,000 to 7,000 acres of tidal marsh and protection and enhancement of 40,000 to 50,000 acres of managed wetlands.

- **Public and Private Land Use**—maintain the heritage of waterfowl hunting and other recreational opportunities and increase the surrounding communities’ awareness of the ecological values of Suisun Marsh.

- **Levee System Integrity**—maintain and improve the Suisun Marsh levee system integrity to protect property, infrastructure, and wildlife habitats from catastrophic flooding.
- **Water Quality**—protect and, where possible improve, water quality for beneficial uses in Suisun Marsh, including estuarine, spawning, and migrating habitat uses for fish species as well as recreational uses and associated wildlife habitat.

The SMP requires that these interrelated and interdependent objectives be implemented to some extent through all SMP actions. For example, the levee system integrity objective will ensure that managed wetlands are protected from catastrophic flooding, thus contributing to meeting the portion of the habitats and ecological processes objective that addresses protection of managed wetlands. Similarly, the restoration of certain properties may help protect and/or improve water quality, and achieving the habitats and ecological processes objective also will help to achieve the private and public land use objective.

Recognizing these relationships, the SMP is proposed to contribute to meeting each of the objectives in parallel over the 30-year planning period by providing adequate restoration both to mitigate impacts related to managed wetland activities and to contribute to recovery of listed species. As such, both restoration and managed wetland activities could proceed simultaneously. An adaptive management plan is an essential component of the SMP, as it provides a mechanism to collect and use information to optimize restoration activity benefits. The SMP also includes annual reporting and tracking of progress through permitting processes.

Appendix A  Suisun Marsh Monitoring and Adaptive Management Plan

Appendix B  Mitigation Monitoring and Reporting Program
1. **Introduction**

The Suisun Marsh Habitat Management, Preservation, and Restoration Plan, abbreviated as the Suisun Marsh Plan (SMP), is a 30-year comprehensive plan designed to address the various conflicts regarding use of Marsh resources, with the focus on achieving an acceptable multi-stakeholder approach to the restoration of tidal wetlands and the management of managed wetlands and their functions. The SMP addresses habitats and ecological process, public and private land use, levee system integrity, and water quality through restoration and managed wetland activities. As such, the SMP is intended to be a flexible, science-based, management plan for Suisun Marsh (Marsh), consistent with the revised Suisun Marsh Preservation Agreement (SMPA) and CALFED Bay-Delta Program (CALFED). It also is intended to set the regulatory foundation for future actions.

1.1. **Summary of Plan Objectives**

The SMP is intended to address the full range of issues in the Marsh, which are linked geographically, ecologically, and politically. The plan objectives are:

- **Habitats and Ecological Processes**—implement the CALFED Ecosystem Restoration Program Plan (ERPP) restoration target for the Suisun Marsh ecoregion of 5,000 to 7,000 acres of tidal marsh and protection and enhancement of 40,000 to 50,000 acres of managed wetlands.

- **Public and Private Land Use**—maintain the heritage of waterfowl hunting and other recreational opportunities and increase the surrounding communities’ awareness of the ecological values of Suisun Marsh.

- **Levee System Integrity**—maintain and improve the Suisun Marsh levee system integrity to protect property, infrastructure, and wildlife habitats from catastrophic flooding.

- **Water Quality**—protect and, where possible improve, water quality for beneficial uses in Suisun Marsh, including estuarine, spawning, and migrating habitat uses for fish species as well as recreational uses and associated wildlife habitat.
The SMP requires that these interrelated and interdependent objectives be implemented to some extent through all SMP actions. For example, the levee system integrity objective will ensure that managed wetlands are protected from catastrophic flooding, thus contributing to meeting the portion of the habitats and ecological processes objective that addresses protection of managed wetlands. Similarly, the restoration of certain properties may help protect and/or improve water quality, and achieving the habitats and ecological processes objective also will help to achieve the private and public land use objective. Recognizing these relationships, the SMP is proposed to contribute to meeting each of the objectives in parallel over the 30-year planning period.

1.2. Background

In 2000, the CALFED Bay-Delta Program (CALFED) Record of Decision (ROD) was signed, which established the Ecosystem Restoration Program (ERP) calling for the restoration of 5,000 to 7,000 acres of tidal wetlands and the protection and enhancement of 40,000 to 50,000 acres of managed wetlands for Stage 1 implementation (CALFED Bay-Delta Program 2000a). In 2001, the CALFED agencies were directed to work with key entities involved with Suisun Marsh to form a charter group to develop a plan for Suisun Marsh that would balance the needs of CALFED, the SMPA, and other plans by protecting and enhancing existing land uses and existing waterfowl and wildlife values, including those associated with the Pacific Flyway, endangered species, and state and federal water project supply quality. The charter group includes all of the local, state, and federal agencies that have jurisdiction or interest in the Marsh. However, the SMP has been developed by a subset of the charter group, the Principal Agencies.

The Principal Agencies are the U.S. Fish and Wildlife Service (USFWS); the U.S. Department of the Interior, Bureau of Reclamation (Reclamation); National Marine Fisheries Service (NMFS); California Department of Fish and Game (DFG); California Department of Water Resources (DWR); Suisun Resource Conservation District (SRCD), representing the interests of private landowners; and California Bay-Delta Authority (CBDA). The Principals have consulted with other participating charter agencies, such as the U.S. Army Corps of Engineers (Corps), the San Francisco Bay Conservation and Development Commission (BCDC), and the State Water Resources Control Board, in developing this plan.

1.3. Suisun Marsh Preservation Agreement and the Corps Regional General Permit 3

The SMPA is a contractual agreement among DFG, DWR, Reclamation, and SRCD intended to mitigate the salinity impacts in the Marsh related to State Water Project (SWP) and Central Valley Project (CVP) operations, and other upstream diversions. The SMPA was first signed in 1987 and since then has
called for the development of many of the salinity control and monitoring facilities in the Marsh. In 2005, the SMPA was revised to replace the construction of additional large-scale salinity management facilities, as outlined in the 1984 Plan of Protection, with landowner-based management activities. As part of the revised SMPA, DWR and Reclamation will provide funding through the Preservation Agreement Implementation Fund (PAI Fund), which is an element of the SMP (described in detail below). Essentially, the PAI Fund is a mechanism that allows DWR and Reclamation to cost-share for certain managed wetland activities that assist landowners in meeting the desired flood and drain cycles to accommodate higher salinities applied to the managed wetlands and maintain existing habitat conditions.

The salinity management facilities and ongoing maintenance by landowners in the Marsh, including those that could be funded with the PAI Fund under the SMP, have been subject to Clean Water Act (CWA) Section 404 permitting through the Corps, and associated federal Endangered Species Act (ESA) compliance and consultation. As part of the 1981 ESA consultation with USFWS, the SMPA agencies have mitigated impacts for the implementation of the Plan of Protection and potential salt marsh harvest mouse (SMHM) habitat through the establishment of conservation and restoration areas, including the Blacklock parcel. In a letter sent to the SMPA agencies in 2007, the USFWS concurred that the completion of the restoration at Blacklock satisfied the goal of the original conservation measures for ongoing impacts on the SMHM, provided benefits to other tidal marsh-dependent species, and mitigated the current ongoing impacts related to managed wetland activities, including those that will be continued under the SMP.

Currently, many of the ongoing maintenance activities implemented in the Marsh are permitted through Corps 404 Regional General Permit (RGP) 3. RGP3 is used by DFG and other landowners (as represented by SRCD) to complete work necessary to maintain and operate managed wetlands. The SMP includes the continuation of these activities, plus an increase in frequency of these activities. Additionally, the SMP includes activities that occur in the Marsh but were not included in RGP3 (such as those activities currently conducted by DWR and Reclamation) and some activities that are new to the Marsh. These specific activities are described in this plan.
2. Plan Objectives

2.1. Habitats and Ecological Processes

The conversion of tidal wetlands as a result of diking resulted in a loss of habitat for many species, including those now listed as threatened or endangered. Development in areas surrounding the Marsh has resulted in introduction and spread of nonnative species, fish entrainment issues, and degradation of water quality. Additionally, there have been water quality effects from drainage operations in managed wetlands. While taking appropriate steps to restore the ecological values of historical tidal wetland habitat, efforts will be made to improve management of managed wetlands and to lessen adverse effects from development, nonnative species, and detrimental land use practices in the secondary management areas and adjacent metropolitan areas.

2.2. Public and Private Land Use

Managed wetlands, tidal wetlands, and uplands, whether publicly or privately owned, provide important wetlands for migratory waterfowl and other resident and migratory wetland-dependent species and opportunities for hunting, fishing, bird watching, and other recreational activities. There is a need to maintain these opportunities as well as improve public stewardship of the Marsh to ensure that the implementation of restoration and managed wetland activities is understood and valued for both public and private land uses.

2.3. Levee System Integrity

Of the more than 200 miles of exterior levees in Suisun Marsh, only about 20 miles along Suisun, Grizzly, and Honker Bays (authorized through Assembly Bill [AB] 360) receive public funding. The public funding for Suisun Marsh levees needs to be expanded from a current limit to address maintenance and improvement activities for exterior levees (levees exposed to tidal action). Additionally, as restoration actions are implemented, some interior levees will be converted to exterior levees and will require reinforcement and more maintenance, and in some instances significant upgrades. Because of current restrictions preventing dredging from sloughs and constraints on importing materials, landowners in the Marsh have maintained their exterior levees using primarily material from ditch cleaning or pond bottom grading for more than a decade, a practice that increases subsidence and potentially weakens the existing levee foundations. These factors combined have exhausted the supply of levee maintenance material in the managed wetlands and have forced maintenance to be deferred on some exterior levees, increasing the risk of catastrophic flooding.
2.4. Water Quality

Multiple factors contribute to the degradation of water quality in Suisun Marsh, including upstream diversion, reduced Sacramento–San Joaquin River Delta (Delta) outflow, state and federal water project operations and diversions, drainage practices in managed wetlands, minimal tidal exchange in dead-end sloughs, urban runoff, erosion, agricultural runoff, discharge from the Fairfield Suisun Sewer District treatment plant to Boynton Slough, and remnant contaminants such as mercury. Improvement of water quality and water quality management practices will benefit the ecological processes for all habitats, including managed and tidal wetlands.
3. Plan Elements

The Plan provides a framework for how restoration and managed wetland activities will be implemented. The Plan also addresses other SMP elements such as levee integrity, water quality, and recreation. The elements of the Plan are summarized below.

- Restoration of tidal wetlands.
- Implementation of managed wetland activities such as increased frequency of current activities in managed wetlands.
- Implementation of new managed wetlands activities, including dredging, placement of new riprap, and installation of new fish screens.
- Implementation of environmental commitments.
- Implementation of adaptive management and the SMPA PAI Fund.

Each of these Plan elements is described below.

3.1. Tidal Wetland Restoration

Restoration of tidal wetlands will help to achieve the restoration goals established for the Marsh by the CALFED ERPP, San Francisco Bay Area Wetlands Ecosystem Goals Project (CALFED Bay-Delta Program 2000b), and USFWS Draft Recovery Plan for Tidal Marsh Ecosystems of Northern and Central California for the Suisun Bay Area Recovery Unit (U.S. Fish and Wildlife Service 2010). Restoration of tidal wetlands in the Marsh will contribute to the recovery of special-status wildlife species, including small mammals (SMHM, Suisun shrew), birds (California clapper rail, California black rail, Suisun song sparrow, salt marsh common yellowthroat), and fish (salmonids, delta smelt, longfin smelt, Sacramento splittail, green sturgeon), and plants (soft bird’s-beak, Suisun thistle, Delta tule pea). Tidal wetland restoration also will be designed to accommodate sea level rise more easily than managed wetlands because the gradual elevations within tidal wetlands will not require the same level of levee maintenance and will provide an area for sediment accretion.

Tidal wetlands are composed of vegetated marsh plains and intertidal and subtidal channels, all of which provide habitat to support the various life history stages of native fish and wildlife species. There are approximately 7,672 acres of tidal wetlands currently in Suisun Marsh. Vegetated tidal wetland plains provide habitat for native plant species such as soft bird’s-beak and Suisun thistle and nesting and foraging habitat for bird species such as California clapper rail, California black rail, Suisun song sparrow, salt marsh common yellowthroat, and some waterfowl species. Tidal marsh plains also contribute terrestrial and benthic invertebrates to the aquatic food web. Smaller fish will use the marsh plain when it is flooded by the higher tides. Tidal marsh pannes, sometimes found within the marsh plains, provide habitat for invertebrates that, in turn, support aquatic and avian communities, and they provide roosting habitat for...
shorebirds and waterfowl. Channels can provide habitat for native fish species such as the delta smelt, longfin smelt, Sacramento splittail, green sturgeon, and outmigrating salmonids. Channels also support phytoplankton production; phytoplankton is a food source for aquatic species and supports benthic invertebrate production, providing a food source for fish, bird, and marine mammal species. The mudflat edges of tidal wetlands, found within channels at low tide and along open water marsh edges, provide habitat for numerous invertebrates and foraging habitat for shorebirds at low tide. Wetlands also provide critical habitat components for species generally considered strictly terrestrial, such as passerine birds (song sparrows) and raptors (short-eared owls and harriers) that feed and/or breed in wetlands and spend some time in adjacent upland habitats. Tidal wetlands along the marsh perimeter allow ecological connectivity to adjacent habitats, thereby supporting a broader range of wildlife species.

The strong salinity gradients in the Marsh, both east-west along the main axis of the estuary, and north-south from the main Suisun Bay channel to the upper reaches of the tides, provide widely differing tidal marsh conditions. Restoration activities in the Marsh will create areas of increased salt concentration. Opening and restoring areas on the west of the Marsh would draw in and capture more saline water from the Bay. This would result in fresher water being drawn from the Delta into the eastern portion of the Marsh. Assuming restoration is distributed among the four regions, more saline areas are expected to be created in the west, which would allow restored areas in the east to remain fresher. Therefore, fresher wetlands would occur in the east-southeast of the Marsh, with greater abundance of the taller tules and bulrushes. Marshes along the west would be more saline, supporting fewer tules and bulrushes and greater amounts of shorter, salt-tolerant wetland plants. While locations such as Goodyear Slough currently have tall tules and rushes, the plant communities may change overtime as salinities vary over years. Thus, between these two end points would be a broad variety of brackish marsh, with the plant communities reflecting the localized salinity regime.

The geographic position of tidal marshes in relation to Suisun Bay exerts additional factors in defining their ecological functions. Proximity to the main Suisun Bay channel connecting the Delta to San Francisco Bay affects population abundance of numerous aquatic species. Proximity to this main channel and also to the large shallow embayments in the southern Marsh also provides a significant sediment supply for marsh accretion; areas removed from these sediment sources would take far longer for natural accretion. Proximity to the edge of the Marsh links sites to adjacent uplands and in some locations to local streams, each of which has a large effect on species that could use a restored marsh; sites around the edges of the Marsh may have the potential for sea level rise resiliency, if they are able to flood adjacent uplands over time and allow marsh landward expansion. In summary, location within Suisun Marsh is a critical factor in directing the ecological functions that a particular restoration site could provide.

Strategically restoring tidal wetlands gradually would provide a range of the above habitat values depending on the initial site conditions (mainly elevation),
the local and regional physical evolution drivers, and location in the Marsh. The ecosystem functions a restored site provides will change over time, with benefits to particular species increasing or decreasing with site evolution. Initially subsided sites may provide primarily subtidal aquatic habitat until the surface has accreted enough sediment for vegetation colonization; that process could take many years to decades (Figure 1) in the more subsided areas that are away from adequate sediment supply, and some locations could remain as open water indefinitely. Subtidal aquatic habitats provide many benefits to numerous species. Diving ducks would have significant foraging habitat, the extent of which varies with the tidal cycle and thus water depth. Submerged and floating aquatic vegetation would provide significant food resources for birds and fish. Phytoplankton and zooplankton production in the water column would support the food web. These areas may provide spawning substrate for some resident fish species.

Note: This plot is for the lower, saline region of the San Francisco estuary and applies to sites sheltered from wind-wave action. The shaded bar identifies the approximate Spartina colonization elevation. Prediction is based on tides at the San Francisco Presidio, no sea level rise, and 550 kilograms per cubic meter (kg/m³) dry density of inorganics typical for San Francisco Bay. Spartina is not found within the marsh; therefore, this is used as an example to depict the relationship between breaching of levees and colonization elevation.

Figure 1. Approximate Timelines of Accretion as a Function of Sediment Supply
Restoration of 5,000 to 7,000 acres of tidal wetlands will be implemented over the 30-year SMP timeframe, and benefits from individual projects would change as elevations rise, vegetation becomes established, and vegetation communities shift over time from low marsh to high marsh conditions. All restored areas are most likely to provide different types and magnitude of benefits at any given period after restoration and at different geographic locations, as local and regional conditions will determine the salinity regime, plant communities, and rate of sedimentation. Existing elevation data (LIDAR [Light Detection and Ranging]) can be used to screen potential properties considered for acquisition and restoration, followed by a more detailed topographic survey. Also, the Charter acquisition considerations shown in Table 1 will be used to screen potential sites. In the interim, a range of subtidal habitat–ecosystem functions will be provided. Additional site-specific analysis, environmental review, and permitting would occur and tier from the SMP EIS/EIR once sites have been selected.

The specific actions that will be implemented as part of the tidal restoration component of the SMP are listed below.

### 3.1.1. Selecting Restoration Sites

Lands suitable for restoration of tidal wetlands will be acquired only from willing sellers. As opportunities present themselves, several factors will be considered for each site, as shown in Table 1. One overarching goal of restoration is to create a diverse mosaic of interconnected habitat types.

The total amount of existing managed wetlands and uplands that could be affected by tidal restoration and managed wetland activities is 52,112 acres. Based on hydrology and facilities, the Marsh has been divided into four regions (Figure 2). The tidal wetland restoration acreages are divided by region to achieve the total CALFED goal as described above and contribute to the USFWS tidal wetlands restoration goals. The USFWS Draft Recovery Plan for Tidal Marsh Ecosystems of Northern and Central California\(^1\) was used as a template in determining the goal of the percentage of restoration acreage per region (U.S. Fish and Wildlife Service 2010). Sites will be selected based on their ability to contribute to restoration goals for each region as shown in Table 2, as well as the considerations described in Table 1.

---

SMP = Suisun Marsh Habitat Management, Preservation, and Restoration Plan.

* The targets were developed for each region based on the different habitat conditions in each region to provide the range of environmental gradients necessary to contribute to the recovery of listed species. These targets complement and are consistent with the Draft Recovery Plan for Tidal Marsh Ecosystems of Northern and Central California. The Adaptive Management Plan will track these targets to ensure restoration benefits for listed species.

Note: Adjustments to the Adaptive Management Plan may result in changes to the targets in each region.

3.1.2. Site Preparation

Once a site has been acquired from a willing seller, the project proponent will undertake several land management activities necessary to prepare the site for restoration. These land management activities will need to occur from the time of acquisition until the time of restoration, which could last anywhere from 1 to 5 or more years.

Each restoration site will be designed to accomplish specific environmental goals by restoring historical conditions. To accomplish this, sites will need to be graded and prepared to re-create flows and hydraulic conditions. As such, ditches previously used for managed wetland flood and drain practices may be filled in with dirt, brush boxes, or other material. Depending on the timing of this activity, material removed from levees, either as breaches or grade-downs, or from grading the restoration site could be used to fill adjacent ditches. In addition to or in lieu of filling in ditches, specific restoration designs may include placement of hay bales, brush boxes, or other slow-degrading material adjacent to levee breaches that block water access to ditches and direct tidal energy into the restoration area. Additionally, restoration preparation may include digging starter channels to increase tidal water connectivity.

Moist soil management likely will be implemented during the growing season to promote the natural production of desired wetland plant species. Depending on site elevations and local salinity regime, these pre-breach managed plant communities may persist following restoration of tidal action or they may be sacrificial. Establishment of vegetation communities prior to inundation is expected to contribute to immediately providing suitable habitat to some species, to discourage establishment of nonnative species upon inundation, to provide for
early subsidence reversal, and to help capture suspended sediment once the site is restored to tidal action. Establishment of these vegetation communities is likely to increase the rate at which the tidal wetland matures, and could occur on the levees or in other areas of the restoration site.

Maintenance of levees and water control structures also may be required during the period prior to restoration of tidal action. Maintenance activities will follow the methods and approaches employed for the diked, managed wetlands. The extent of maintenance required will depend on conditions at the time of acquisition and changes in those conditions that occur over time. However, structures peculiar to managed wetlands, including duck blinds and derelict pipelines, likely will be removed. Support apparatus for water control structures often requires levee excavation and pile, culvert, flashboard riser, and gate removal. The removal of water control structures will depend on the moist soil management regime prior to breaching, but their eventual removal is expected at all sites.

3.1.3. Selecting Breach Location(s) at Restoration Site

Restoration will be accomplished by breaching and/or lowering existing exterior levees to restore tidal inundation. Breaching levees would occur after ground-disturbing activities are completed and in the summer when covered fish species are not present. Depending on site-specific goals, levee modifications will be made in various ways by manipulating the opening width, depth, and/or slope angle. Breach edges may require scour protection with rock, geotextiles, or piles. Alternatively, long reaches of levee may be graded down to lower elevations—most likely between mean sea level and mean higher-high water (MHHW). Material will be used to create topographic variability and encourage diverse plant communities and shallow tidal habitat.

Breach location, number, and size will be chosen based on two considerations. The first consideration is to maximize the ecological benefits of the restoration. Considerations will include ability to reconnect existing tidal channel networks from the site’s history as a tidal marsh if those channels remain, providing suitable connectivity to the tidal source waterways, orientation relative to winds and currents to promote natural sedimentation and access to aquatic organisms, and constructability. The second consideration is to minimize upstream tidal muting, tidal elevation changes, slough channel scour, and hydraulic changes, and restoration projects will be designed to ensure that changes in tidal flows remain below about 1 foot per second (fps). In general, breaches on larger channels or multiple breaches will reduce the effects of the increased tidal flows on tidal elevations and velocities. If feasible based on site-specific conditions, breach locations will be located in areas that have minimal or no existing tidal wetlands on channel berms or in locations where the tidal wetland habitat value is lowest (e.g., riprap levee sections).
As part of each site-specific restoration action, project proponents will use an accurate tidal hydraulics and salinity model (e.g., the Resource Management Associates [RMA] Bay-Delta model) to simulate the proposed action to ensure the impacts on scour, sedimentation, salinity, and other hydraulic processes do not exceed those described in the SMP Environmental Impact Statement/Environmental Impact Report (EIS/EIR). This information will be used to adjust designs of restoration projects and other activities to minimize adverse impacts on tidal elevations and velocities, or other site-specific characteristics, in the restoration site and/or in Marsh channels adjacent to restoration projects; minimize salinity effects at upstream Delta locations; and potentially create benefits related to scour and sedimentation.

### 3.1.4. Upgrading or Constructing New Exterior Levees

To protect adjacent properties from increased risk of flooding, existing interior levees may be upgraded or new exterior levees will be constructed prior to breaching the levee. These new or upgraded levees will include brush boxes or other biotechnical wave dissipaters to protect the levee from wind and wave erosion.

Habitat levees that include benches or berms also may be constructed, which will provide similar wind- and wave-action protection as well as opportunities for high marsh/upland transition habitat. The construction of habitat levees will depend on cost and availability of fill. Habitat levees are low, wide, gently sloping vegetated levees, which may be overtopped during storm surges with nominal eroding or destabilizing. Actual details of the location and number of levees will be identified on a site-specific basis as habitat restoration projects are developed. The levee designs will be engineered appropriately at the time of the site selection. Actual detail of each levee will also be developed on a site-specific basis once the location for the levee is selected; however, the upper substrate or upper layer of the habitat levee would be composed of non-compacted material that would be suitable for planting and establishment of marsh vegetation. The levees created as part of tidal habitat restoration will have an extension of the levee berm on the bay side (i.e., on the restoration project side). The standard section of levee (e.g., base and crown) will be composed of the compacted material, but the extended berm will have non-compacted material and will be suitable for planting and the establishment of marsh vegetation. Habitat levees are designed to allow intermittent flooding; minimize dispersal and denning of terrestrial predators; reestablish facsimiles of marsh topographic gradients; accommodate natural patterns of debris deposition and shoreline disturbance; and provide wave-energy buffers (Interagency Ecological Program 2007).

Habitat levees may be planted and seeded with native marsh species and/or allowed to colonize naturally with native and naturalized species. This habitat will promote intertidal zones and mudflats that support various species that rely on a gradually transitioning marsh plain. Habitat levee design and locations will
vary by site but are expected to include the widening of existing interior levees by 15 to 30 feet with a gradual slope or the construction of new interior levees or islands. Specifically, these benches or berms will be designed to create mid and high marsh habitat for dependent species and will be guided at least partially by information obtained through the adaptive management process. It is expected that benches or berms that support habitat for these species will benefit many other species.

Habitat levees will be constructed from resources available at the time of construction and may include channel dredged material collected in bays and sloughs in the plan area, dredged material from outside the plan area, or material excavated within the tidal restoration area or other areas of the Marsh.

3.2. Implement Managed Wetland Activities on 44,000 to 46,000 Acres

The managed wetlands of Suisun Marsh are managed specifically for duck hunting activities but also provide important habitat for a variety of resident and migratory waterfowl and shorebirds and other native and special-status species; protection of these areas is a goal of many agencies and programs, including the Central Valley Joint Venture program and CALFED. These wetlands, which are managed for a diversity of wetland vegetation and other wetland wildlife food plants, are important as feeding and roosting areas for species such as geese, mallards, pintails, widgeons, and gadwalls. Managed wetlands also provide breeding habitat for shorebirds, which nest in a wide range of habitats from unvegetated wetland flats to uplands. Spring drawdowns practiced by Suisun Marsh wetland managers in conjunction with adjacent uplands provide ideal foraging conditions for migrating shorebirds.

Managed wetlands provide valuable habitat for a variety of non-waterfowl birds, mammals, reptiles, and amphibians. Birds such as Suisun song sparrow, salt marsh common yellowthroat, shorebirds, and ring-necked pheasant forage and nest in the managed wetlands. Managed wetlands support mammals such as SMHM, northern river otter, coyote, raccoon, striped skunk, black-tailed jackrabbit, common muskrat, and tule elk, as well as native reptiles and amphibians (e.g., western pond turtle, gopher snake).

Managed wetlands face challenges and constraints such as aging water management facilities, threatened and endangered species regulations, subsidence, mosquito abatement regulations, and water quality issues, including salinity. Additionally, the aging levee system, which is difficult to maintain because of a lack of appropriate levee source materials and regulatory constraints, compromises the managed wetland system.

The intended outcomes of the managed wetlands activities described below are to maintain and improve habitat conditions and minimize or avoid adverse effects of wetland operations. For managed wetlands, the optimum flood and drain cycle is 30 days. The activities described below provide a suite of tools that can
be used to maintain and improve levee stability and the 30-day flood and drain cycle. As described above, the restoration and enhancement goals of the ERPP include protecting and enhancing 40,000 to 50,000 acres of managed wetlands. The SMP assumes that managed wetlands are enhanced by improving levees and the flood and drain cycle because it allows managed wetlands to be managed as effectively as possible.

The ability for managed wetlands to improve habitat is also dependent on the availability of lower-salinity water. DWR/Reclamation facilities and salinity stations are used to reduce water salinity and to distribute less saline water to managed wetlands. These facilities and stations must be maintained in order to function as intended.

Most of the managed wetland activities described below are already occurring in the Marsh. Some of the current activities will be modified, and new activities will be conducted. Many of the current activities will qualify for the SMPA PAI Fund, which is described below. Under the SMP, many of these activities will increase in frequency, primarily because of an increase in funding provided by the PAI Fund.

3.2.1. Increased Frequency of Currently Implemented Managed Wetland Activities

DFG, DWR, and landowners (as represented by SRCD) currently maintain their facilities and/or properties in the Marsh by implementing the actions listed below. Additionally, Reclamation contributes funding to DWR to implement operations and maintenance of facilities that mitigate the effects of the CVP/SWP, including Roaring River Distribution System (RRDS), Morrow Island Distribution System (MIDS), Goodyear Slough Outfall, salinity monitoring stations, and other facilities and/or properties. Table 3 gives a comprehensive description of most of the activities conducted by these agencies and landowners in the Marsh, although the activities each implements depend on their individual facilities, properties, and other factors. Some of these actions are expected to increase in frequency because of the increase in effort to support the managed wetland targets as well as the PAI Fund (described below), and to ensure continuing functionality of state/federal facilities. The current level of activity combined with the proposed new activities make up the total work needed to support managed wetland operations. Increasing the current level of work and implementing the new activities will help SRCD and DFG meet the SMP managed wetland goals related to levees and flood and drain cycles and help DWR and Reclamation meet their contractual and mitigation requirements for the effects of the SWP and CVP. All activities will be implemented by DFG, landowners (as represented by SRCD), and/or DWR except as noted. Descriptions of each activity are provided in the subsections following Table 3.

cy = cubic yards.

### 3.2.2. Repairing Existing Interior and Exterior Levees

This action involves the improvement or repair of levees by using spoils from other permitted activities such as clearing interior ditches, constructing new interior ditches, or grading pond bottoms. Vegetation growth on levees can require mowing to maintain condition and to assess repair needs. The spoils will be placed on the crown of the levee with an excavator, dozer, or box scraper. On rare occasions, exterior levee integrity is compromised (from rodent holes, storm damage, or unanticipated overtopping of the levee crown), allowing uncontrollable tidal flows to enter the managed wetland that can cause levee breaches. If the exterior levee breach can be repaired using on-site material consistent with existing permit terms and conditions, the levee integrity is restored on the next appropriate low tide cycle. See managed wetlands environmental commitments (Section 4) for additional discussion of this activity. Aggregate base rock may be placed on the crown of levees to prevent road surface degradation. Work generally will occur in late summer, and approximately 500 linear feet of levee can be repaired per day.

### 3.2.3. Coring Existing Interior Levees

The coring of levees is intended to stop the flow of water through rodent holes and cracks in levees. To core a levee, typically a 2-foot-wide trench (depending on the width of the excavator bucket) is excavated in the levee crown using a long-reach excavator or backhoe, and the material is placed on the crown of the levee adjacent to the excavation site. The trench then is backfilled immediately
using the same material that was excavated. The material is compacted during
the backfilling process to seal the levee. If a rodent hole is identified, its entire
length may need to be excavated to stop the flow of water and prevent future
burrowing by small mammals. Coring of levees generally is performed between
July and September, and approximately 700 feet can be completed in 1 day.

3.2.4. Grading Pond Bottoms for Water Circulation

To improve water circulation by re-contouring low areas and raising pond
bottoms and provide material for levee maintenance, material is graded from
high-ground areas or pond bottoms. The raising of low pond bottom areas
improves circulation and drainage in the managed wetlands. Grading also can
include the creation or maintenance of swales, typically 2 feet deep with gradual
slopes. This work is completed with a box scraper pulled by a low–ground
pressure dozer or tractor. Work is generally done in June through August.
Approximately 700 cubic yards can be graded per day.

3.2.5. Creating Pond Bottom Spreader V-Ditches

V-ditches are 18-by-18-inch or 24-by-24-inch ditches created by pulling a
V-ditch plow behind a tractor. These V-ditches facilitate circulation and
drainage of low areas and sinks. Occasionally, a ditch may be constructed in
high areas to improve drainage by connecting an isolated wet area to other
draining wet areas. Typically, these ditches silt in quickly and last only 1 to
2 years after creation. These ditches normally are created after the ponds have
drained for the season, generally in June through August, and 2,000 feet can be
constructed per day. Spoil materials typically remain on the sides of the V-
ditches, although they may be spread back into the pond bottom to further
improve the low areas, or they can be flattened adjacent to the V-ditch.

3.2.6. Repairing Existing Interior Water Control
Structures

This repair involves the replacement of component parts of pipes through interior
levees (gates, stubs, or couplers) but not replacement of the pipe itself. Work is
done by hand (uncoupling the old structure and re-coupling the new structure),
and generally a ground crew removes the damaged structure and installs the new
structure on the end on the existing pipe. This work typically is completed in the
summer, when the managed wetlands are dry.
3.2.7. Replacing Pipe for Existing Water Control Structures or Installing New Interior Water Control Structures

This activity includes the replacement of a pipe for an existing interior water control structure or the installation of a pipe for a new interior water control structure. If a new structure is being installed, the new structure is assembled on the crown of the levee, a trench is excavated laterally through the levee, the new pipe is placed in the trench, the trench is backfilled, and the fill is compacted. If a pipe is being replaced, the trench is excavated at the site of the old pipe, and that pipe is removed. Similar to installing new pipe, the replacement pipe is placed in the trench and backfilled. However, when feasible, new drainage pipes will be placed where they can be consolidated or drain into an existing ditch. Occasionally, an interior ditch cannot be drained sufficiently for pipe replacement. In these instances sheet piles may be used to retain the water temporarily until the pipe is replaced.

Many water control structures have walkways that run from the levee to the end of the pipe. These walkways include pilings, walkway boards, and handrails. These structures strengthen the gate by providing a grounded structure for frame attachment, and they provide a means by which wetland managers can access the gate for operation. Any necessary repair to these structures typically is done during pipe replacement. However, some repairs may need to be done more frequently, especially replacement of walkway boards or handrails.

This work typically is completed in the summer when the managed wetlands are dry.

3.2.8. Installing New Blinds and Relocating, Replacing, or Removing Existing Blinds

Duck blinds are plastic, fiberglass, or metal structures (3’ x 4’ x 8’) placed in the ground to conceal the hunter. When an in-ground blind is replaced, the old blind is excavated from the ground, and a new blind is placed in the void, which can be as deep as 4 feet. This work is completed with a dozer and/or excavator. The blind is placed and secured with vertical timbers and cross timbers that are pushed into the ground adjacent to the blind. Then material from the pond bottom is graded to conceal the sides of the blind.

3.2.9. Discing Managed Wetlands

Discing is done on the landside of levees in the spring or late summer to clear problematic vegetation, reduce the production of vector mosquitoes, break up the soil for seedbed preparation, smooth excavated material, fill cracks in soil, or create fire breaks. A disc is pulled behind a tractor or dozer. Depending upon the wetland management and vegetation objectives, discing can occur annually in
upland areas to promote annual grasses and cereal grain production and once every 2 to 5 years in wetland areas to set back plant succession. Discing is voluntarily limited to one fifth of a property area per year (Suisun Resource Conservation District 1998).

### 3.2.10. Installing Drain Pumps and Platforms

Drain pumps are installed on wooden platforms built to support them. The pump and platform are installed on the inland side of the exterior levee. Occasionally, the pump discharge pipe will be set high in the profile of the exterior levee so that the pipe does not limit levee access but allows discharge at high tidal levels.

### 3.2.11. Replacing Riprap on Interior Levees

Riprap is replaced on interior levees in the minimum amount necessary for bank stabilization and in areas around water control structures where water flow and eddies erode the ditch bank and interior levee toe. Riprap will be placed on interior levee banks only in those areas with existing riprap. Riprap is placed on the interior levees using a long-reach excavator that is located on the levee crown. Approximately 300 feet of riprap can be placed per day. Riprap generally is replaced during July through September.

### 3.2.12. Replacing Riprap on Exterior Levees

Riprap is replaced on the tidal side of exterior levees in the minimum amount necessary for bank stabilization. Riprap will be placed on exterior levee banks only in those areas with existing riprap. Those areas that receive direct wave impacts historically have been fortified with riprap and require periodic maintenance. Riprap is placed on the tidal side of exterior levees using a long-reach excavator that is located on the levee crown, or by barge with a dragline or clamshell dredge. The barge method is used less frequently, as it requires greater channel widths and depths and is more expensive. Riprap generally is replaced during July through September.

### 3.2.13. Coring Existing Exterior Levees

This activity is the same as described for interior levees.
3.2.14. Repairing Exterior Water Control Structures (Gates, Couplers, and Risers)

Repairing exterior water control structures involves the replacement of components of pipes through exterior levees (gates, stubs, or couplers) but does not involve the replacement of the pipe itself. All work is completed at low tide to allow access to the pipe and typically does not involve any excavation of sediments from the exterior slough. The repairs are generally done during July through September. In-water work is done by hand (uncoupling the old structure and re-coupling the new structure), and generally a ground crew lifts the damaged structure out of the water and lowers the new structure into place.

3.2.15. Installing or Replacing Pipe for Existing Exterior Flood or Dual-Purpose Gates

This activity is the replacement of an exterior water control structure (pipe, gates, stubs, and couplers) that is used to either flood or drain managed wetlands. There are no restrictions on the size of a drainpipe. For floodgates and dual-purpose gates (flood and drain) that divert water from tidal sloughs, however, the overall capacity of the diversion for that parcel may not be enlarged. In the past, water control structures typically were constructed of corrugated metal pipe. Because of the corrosive environment of the Marsh, these pipes often begin leaking and fail in 8 to 15 years. If an exterior pipe leaks, habitat management and maintenance activities would be compromised as a result of uncontrollable flooding of the managed wetland. Therefore, metal pipes typically are replaced with high-density polyethylene (HDPE) pipes.

When a pipe is replaced, a new pipe and appurtenant structures are assembled on the crown of the levee with the appropriate control structure components attached to each end of the pipe. A trench is excavated in the exterior levee over the old pipe, and the pipe is removed. All replacement activity is completed in one low tide. Replacement pipes typically are placed in the same location as the existing structure, the trench is backfilled, and the backfilled material is compacted. Either a dozer or an excavator is used to excavate the trench, and generally an excavator is used to install the replacement pipe. The backfill material is compacted with a dozer and/or excavator. Replacement of the pipes takes approximately 4 days and generally is done March through September. The first day is mobilization of equipment and materials, the second day is assembly and preparation for installation, the third day is installation, and the fourth day is demobilization and site clean-up.

If a new drainpipe is required, it will be installed at a location where discharge channels already exist or exterior levees have minimal vegetation. The new structure is assembled on the crown of the levee, usually with a flap gate or screw flap on the outside and flashboard riser or screw gate on the inside. Installing a new drainpipe requires the same types of equipment and takes the same amount of time as replacing an old drainpipe.
3.2.16. Installing, Repairing, or Re-installing Water Control Bulkheads

Bulkheads are built to stabilize and strengthen levees exposed to highly energetic water flows or wave energy. These structures typically are installed near water control structures and prevent the erosion of soils at the toe of the levee and ditch banks. Exterior work is done at low tide and does not involve any excavation of sediments from the exterior slough. In-water work is done by hand (unbolting the old boards and/or bolting a new structure together), and generally a ground crew lifts the old boards out of the water and lowers the new boards into place. A new bulkhead may be constructed to strengthen newly excavated sections of levee, and to help avoid additional turbidity after installation of exterior water controls by containing loose soils that otherwise may fall into the exterior slough. Bulkheads can be constructed from wood or vinyl or metal sheetpile. This activity generally will be implemented in the summer months.

3.2.17. Removal of Floating Debris from Pipes, Trash Racks, and Other Structures

Floating vegetative debris and other debris, such as wood and trash, often accumulate in front of pipes, trash racks, and other structures. This debris typically is removed using a long-reach excavator. Material is disposed of outside the Marsh. Work is done annually, generally during the summer months.

3.2.18. Installing Alternative Bank Protection such as Brush Boxes, Biotechnical Wave Dissipaters, and Vegetation on Exterior and Interior Levees

As described above, vegetation applications, including brush boxes, may be appropriate and effective mechanisms for controlling erosion of levees. Pursuant to the 1994 Biological Opinions (BOs) from NMFS and the USFWS, SRCD was required to employ levee maintenance methods that do not use riprap. Brush boxes use natural materials and native plants for capturing sediment to stabilize and protect exterior levees while also providing fish habitat. The installations generally are done during July through September.

Brush boxes, brush bundles, and ballast buckets are placed below the mean high water mark and anchored with tree stakes. Brush boxes and brush bundles are generally dead branches that are staked into the ground or wrapped in coconut fiber. Ballast buckets are organic, biodegradable buckets planted with native wetland species such as tule, three-corner bulrush, and Baltic rush. As the technology is developed further, alternative materials or installation methods may be used. The installation of brush boxes and ballast buckets does not involve any in-water work because all work will be done at low tide. This work is done...
entirely by hand, reducing the sedimentation that can occur with mechanical work. After the build-up of sediment and the growth of native plants over time, the exterior levee will be stabilized and protected from further erosion, and habitat will be established for fish and the macroinvertebrates on which they feed.

Integrated vegetation solutions are desirable to provide low maintenance “living” bank protection and wave-energy dissipation. Applications of these solutions are limited by the local channel velocities and depth, wind fetch, and exposure to wake. If the tidal hydraulic regime is suitable for the establishment of vegetation capable of resisting high channel velocities and wave energy, vegetation will be incorporated into the erosion protection design. This will reduce the future maintenance costs of erosion protection. The following criteria will be considered in determining the appropriateness of vegetation, either by itself or in combination with riprap, at each site.

- When channel velocities are low enough to prevent loss, vegetation solutions can be installed to halt erosion processes along levee slopes and natural channel bank sections.
- If channel depth on the face of the levee slope is less than 3 feet below mean tide level (MTL), i.e., mid tide level, and the levee slope is less than 3:1 (H:V), vegetation solutions can be installed to halt erosion processes along levee slopes and natural channel bank sections.
- If levee slopes can provide suitable foundations, brush boxes can be installed at various elevations to create a “benched” sequence up the slope and reduce or stop erosion in areas where scallop failures have occurred.
- If shallow water, shallow slopes, benches, or shoal exists, vegetation can be installed to greatly reduce wake energy and provide a low-maintenance erosion-reduction measure.
- If fetch length is less than 1,000 feet in the direction of the predominant southeast to southwest winds during high-water conditions (e.g., winter storms, spring tides), or prevailing winds during all other times (typically from the west) vegetation solutions should be applied to the upper slope of the levee to dissipate wind-driven waves and reduce erosion potential.

3.2.19. Constructing Cofferdams in Managed Wetlands

Cofferdams are temporary earthen structures used to cross interior ditches or prevent interior water from flowing into construction sites, in support of other permitted construction activities (e.g., exterior pipe replacement) and required best management practices (BMPs). Cofferdams are temporary in nature and are constructed from material from the levee toe, pond-bottom grading, or other excavated areas in the managed wetlands. The volume of material needed to transverse the ditch is limited to that required to stop the flow of water and provide adequate width to support equipment access to both sides of the ditch. During installation, a long-reach excavator or dozer places or pushes material
from the adjacent levee crown or field area into the ditch. Upon completion of the associated work activities, the cofferdam or crossing is excavated and removed from the ditch, and the ditch is restored to its original width and depth. Upon removal of the cofferdam, all material is placed on the crown and backslope of the exterior levee or is spread out over the adjacent interior ditch bank or levee. An alternative to cofferdams is sheetpile that can be driven into the levee with a long-reach excavator and removed upon completion of construction. Sheetpiles could be used instead of or in conjunction with cofferdams. This activity generally will be implemented in the summer months.

3.2.20. Suisun Marsh Salinity Control Gate Repair and Maintenance

Flashboards are installed and removed on an annual basis by means of either a land-based crane on the banks of Montezuma Slough or a barge crane. Repairs and maintenance include servicing, replacing, and installing sections and pieces of the radial gates or boat locks that are connected to or associated with the entire facility. Most work is done above water from a boat or the superstructure while sections are hoisted out of the water. This activity is conducted by DWR.

3.2.21. Roaring River Distribution System Fish Screen Cleaning

The fish screens are cleaned by successively lifting each of the stationary vertical screen panels out of the water and pressure washing the silt and vegetation accumulation off of the screens. During the flood-up season (generally August through October), this activity can be conducted up to once a day. During the rest of the year, this activity is conducted less frequently on an as-needed basis. This activity is conducted by DWR.

3.2.22. Installing New Fish Screen Facilities

Fish screens are installed at managed wetland water intakes (flood pipes) to prevent fish from swimming or being drawn into managed wetlands. The installation of fish screens was permitted in the 1995 RGP (diversions are screened).

Wetland impacts from screening diversions to protect fish will not exceed 1,000 square feet per year or a total of 30,000 square feet over the 30-year plan period. All Suisun Marsh screens will be designed to comply with USFWS delta smelt approach velocities of 0.2 fps, which are well below required approach velocities for salmon.

There are many different designs for fish screens in the Delta and Suisun Marsh. Site-specific considerations, such as acreage served, diversion volume, and
channel and diversion point configuration, will dictate screen design. The stainless steel conical 8-foot, 10-foot, and 12-foot fish screens have proved to be the most efficient design for small diversions screened in Suisun Marsh. These screens were designed to be removable from the crown of the exterior levee with a standard boom truck or excavator. This aspect of the design allows normal maintenance to be conducted in the dry, and the screens can be removed from the tidal slough and placed on a storage platform for inspection and maintenance. Normal maintenance includes power washing the screens, replacing cathodic protection (zinc or magnesium anodes), replacing cleaning brushes, and general inspection.

Typically, fish screens are installed at an existing diversion structure; therefore, there is an existing channel or basin in the tidal area and a supply ditch in the managed wetland. However, consolidation of unscreened diversions may require a new diversion location to serve multiple wetland units at one location. The fish screen platform is supported by four pilings that are pushed into the bay mud at the toe of the exterior levee. The conical fish screen support platform and diversion pipe are placed on top of these support pilings and installed through the exterior levee. These construction methods are similar to exterior pipe replacement and bulkhead repair or installation. All other work activities for screen installation are completed at the toe of the exterior levee on the landside of the levee. These activities include water control installation, storage platform construction, and control center platform installation. This activity generally will be implemented in the summer months.

3.2.23. Salinity Monitoring Station Maintenance, Repair, and Replacement

Infrequent major maintenance activities do not involve work done in the water. This includes repairs to walkways, equipment housing, or other wood, plastic, or metal structures. This also includes installation, removal, replacement, repair, or modification of monitoring instrumentation within the equipment housing. These activities are done twice per year.

Weekly maintenance activities include collecting data from the electronic equipment at the site and the calibration and cleaning of the probes. With the exception of lowering the probes in the water, these activities are done above the water or adjacent to the water on the levee bank.

Activities to be conducted periodically in the water by hand include cleaning or replacing the probe mounting equipment, resetting of water stage gage, cleaning probe pipes, and replacing the dimple collar to suppress wave action. On the remaining stations with stilling wells, clearing accumulated sediment from the stilling well is done by flushing the stilling well with water pumped from the adjacent area.

Stilling well replacement and walkway/platform piling replacement includes removal by tractors and trucks operated from the existing roadway/levee and
excavators or cranes operated from the roadway/levee or barge. Work generally is scheduled during the dry months of summer and fall. This activity is performed by DWR about once every 5 to 10 years at a site.

DWR gradually is moving away from the use of stilling wells and moving toward using pressure transducers to measure water surface elevation. Pressure transducers (as well as the other transducers in the bundle) are suspended in the water above the bottom.

3.2.24. Salinity Station Relocation, Installation, and Removal

Salinity stations need to be relocated, installed, or removed due to regulatory requirements, physical constraints, the need to obtain more reliable data, the data no longer being required, or for other reasons. Maintenance equipment may include trucks, bucket excavators, small cranes, boats, barges, and other equipment as required. Work generally is scheduled during the dry months, June through September.

When a salinity station is removed, it is done by hand when feasible. Otherwise, tractors and trucks operated from the existing roadway/levee and excavators or cranes operated from the roadway/levee or barges are used. All components of the station will be removed. This includes the stilling well culvert, and pilings supporting the walkway will be removed from the levee slope/river bottom. Materials from the removed station are disposed of at an approved off-site location. The total disturbance will not exceed 400 square feet. The removal of a monitoring station usually takes about 8 hours over the course of approximately 3 days.

New monitoring stations are installed on a levee when possible or in water when location on a levee is not feasible. A new station may include installation of salinity measurement equipment with equipment housing. Stations that cannot be located on the levee will require a platform to support the equipment housing, a walkway to access the platform, and pilings to support the platform and walkway. Stilling wells may be installed. Alternatively, pressure transducer equipment will be attached to structures in the water, such as pilings, to enable measurements to be taken in the water column without requiring disturbance of the substrate during installation or maintenance. The footprint for the walkway (actual fill) is less than 2 cubic feet. Installation of a monitoring station usually takes approximately 4 days, involves the use of a truck to haul equipment, and may require an excavator and small boat to install the stilling basin. The total disturbance will not exceed 50 square feet. This activity is conducted by DWR.
3.3. Modification of Currently Implemented Activities

Only three activities currently implemented will be modified under the SMP. The activities themselves—clearing existing interior ditches, constructing new interior ditches, and repairing exterior levees—will not change, but how the activities are administered will change. These activities will be implemented by DFG, landowners (as represented by SRCD), and/or DWR. This includes RRDS, MIDS, Goodyear Slough Outfall, and other facilities and/or properties.

3.3.1. Clearing Existing Interior Ditches

This action is the removal of accumulated silt, emergent vegetation, and aquatic vegetation from interior ditches with an excavator to eliminate water-flow restrictions. Approximately 900 linear feet of ditch can be cleared in 1 day. The RRDS includes a square-shaped 40-acre intake area that receives water from the water control structures behind the fish screen and allows sediment to settle out of the water prior to its flowing into the RRDS ditch. Although this area is not linear like a ditch, it is similar to ditches in that it is an area with open water, boarded by levees, that may have emergent vegetation growth due to excess silt accumulation. Removal generally will be done during the months of June through September. A long-reach excavator, harvester, or other drag methods may be used to remove the material.

The material will be spread evenly on adjacent land. However, spoils also may be sidecast and left adjacent to the ditch for up to 1 year, then must be used for an authorized activity (levee maintenance or grading) or removed to an area outside Corps jurisdiction (crown of a levee). In this case, spoils are moved using a dozer or box scraper. Currently, sidecast materials may be left in place to dry for only a month. SRCD, DFG, DWR, and Reclamation propose that this period be extended to a year to ensure that all materials are dried before they are put to beneficial use.

3.3.2. Constructing New Interior Ditches

This action is the removal of pond bottom material with an excavator to create a new interior ditch for improved water circulation. Approximately 600 linear feet of ditch can be constructed in 1 day, and work generally will be conducted during the months of June through August. A long-reach excavator may be used to remove the silt and spread materials evenly on adjacent land. However, spoils may be sidecast and left adjacent to the ditch for up to 1 year; then they must be used for an authorized activity (levee maintenance or grading) or removed to an area outside Corps jurisdiction (crown of a levee). Spoils are moved using a dozer or box scraper.
Similar to clearing existing ditches, sidecast materials currently may be left in place to dry for only a month. SRCD, DFG, DWR, and Reclamation propose this period be extended to a year to ensure that all materials are dried before put to beneficial use.

### 3.3.3. Repairing Existing Exterior Levees

The most common practices for repairing exterior existing levees in Suisun Marsh involve the removal of accumulated silt and vegetation from water circulation ditches in managed wetlands and placement of spoil material on the crown of adjacent levees to raise the crown to its original or design height and/or improving interior side slopes. Materials may be imported from an upland source within or outside the Marsh for beneficial uses of dredged materials or from the Long-Term Management Strategy (LTMS). A potential additional material source, dredging from tidal sloughs, is described below under Section 3.4, New Activities.

Repair of existing levees typically occurs from June through September. Approximately 800 linear feet can be completed in 1 day.

It is unlikely that a significant amount of levee repair material would be lost to the outboard side of an exterior levee below the mean high water line. Any material that might trickle down the outside slope of the levee from the crown probably would not affect vegetated areas and may cause only slight and very temporary turbidity.

This activity currently is limited based on acreage of each parcel protected by the exterior levee. The change is to limit work based on actual lineal footage of each ownership. This change was proposed because some small-acreage properties may have significant lengths of exterior levee (e.g., a long, narrow parcel), and a large acreage property may have minimal or no exterior levees but be protected by the small-property exterior levee. This administrative change would provide landowners with a more appropriate limit for maintenance of exterior levees. Placement of up to 1.5 cubic yards of levee material per linear foot on average for annual work activities will occur. One levee segment may require no work in a given year, and a different levee segment may require 3.0 cubic yards per linear foot because of flood damage. This will average out over the individual properties’ total levee system. This slight change in how permitted volumes are calculated is not expected to change the overall patterns of activities conducted in the Marsh. However, the frequency of work is expected to increase to meet the enhancement objective.

### 3.4. New Activities

New activities are activities that have not been implemented in the Marsh, or that have not been implemented in so long that they are not considered part of the existing baseline condition. These new activities will be implemented by DFG,
landowners (as represented by SRCD), and/or DWR. This includes RRDS, MIDS, Goodyear Slough Outfall, and other facilities and/or properties. These new activities are described below.

3.4.1. **Dredging from Tidal Sloughs as Source Material for Exterior Levee Maintenance and to Remove Sediment around Fish Screens and Other Areas**

A dredging program will be implemented to provide materials for deferred and anticipated levee maintenance needs. A total of 3 million cubic yards of materials will be dredged from major and minor tidal sloughs and bays over the 30-year SMP implementation period. However, over time, as tidal restoration occurs, the number of exterior levees in the Marsh may decrease, thus reducing the amount of dredging required to maintain Marsh levees. Any reduction in dredging will occur over time and will be concurrent with the implementation of the restoration. This activity will be performed during the dredging windows of August through November.

Up to approximately 100,000 cubic yards of material will be dredged annually. However, as described above, as tidal restoration occurs the number of exterior levees in the Marsh may decrease, thus reducing the amount of dredging required to maintain Marsh levees. The annual allotment will be divided between state and private property, depending on need, and limited to 2.1 cubic yards per linear foot of channel, based on the linear extent of exterior levees on each property or the length of dredger cut. This limitation will be provided as a general guideline; however, flexibility would be necessary in case of special conditions, such as catastrophic levee failure. The proposed volume may be reduced, in any given year, if supplemental material is available through beneficial reuse of suitable dredged materials (e.g., LTMS or other operations).

Some exterior levee segments have vegetation growth on the levee toe that extends out into the bay or slough. Repair of levee segments with this vegetation will be avoided if the tidal berm is more than 50 feet wide. Dredging could be done within dredger cuts, which transect wide berms, and salinity stations located on the edge of such berms. Dredging from the center channel will be done to avoid emergent vegetation, and other areas with vegetation will be avoided. The approximate cubic yards and acreage of other habitat types per region proposed for dredging per year is shown in Tables 4 and 5. Minor sloughs include all sloughs except Montezuma and Suisun. Dredger cuts are small, linear channel areas isolated by or transecting a vegetated berm. These are channels that were created immediately adjacent to the toe of the exterior levees during original levee construction or are channels that run from water control structures to bays or sloughs that were previously created to facilitate water drainage.

Dredging activities will be tracked by SRCD using geographic information systems (GIS) to ensure that it does not occur more than once every 3 years in any location, and would not remove material deeper than 4 feet per dredging cycle. The actual dredging locations will be based on needed levee improvements, but will be limited by region, annual limits, habitat types, and frequency in any one location as described above.

A clamshell dredge or long-reach excavator will be used to dredge in the Marsh. The long-reach excavator will dredge from the levee crown or from a barge. Clamshell dredging could take place either from a barge within the slough channel or from the top of a levee, depending on restrictions caused by vegetation on channel banks or the width of a channel. Barge clamshell dredges are not self-propelling and therefore need a small tugboat to maneuver in the channel. From a barge, the operation will begin when the bucket assembly, attached by a boom (up to 100 feet), is lowered into the channel to collect sediments. It will scoop up to 5 cubic yards of consolidated bay mud and deposit it on the land side of the levee or crown adjacent to the channel. In limited instances, materials may be used for exterior levee maintenance in areas not adjacent to the dredged material source. The clamshell dredge or long-reach excavator may sit on top of the levee and scoop up to 5 cubic yards of consolidated bay mud from the channel bottom, using the same method as from a barge, and deposit the dredged material on the landside backslope, crown, or the levee slope on the bay/slough side if it is devoid of vegetation.
Once material is placed, an excavator bucket will be used to compact the material against the levee to make it as smooth as possible. After 2–3 months of drying time, the material will be disced and graded to integrate the new materials with the existing levee. Minimal materials enter the interior managed wetland or bay/slough because the materials are deliberately placed and kept on the crown and slopes of the levee.

Dredging could occur in the center of slough channels, adjacent to water control structures or culverts, in salinity station locations, in the location of the Suisun Marsh Salinity Control Gates, adjacent to fish screen structures, and in historical dredger cuts. Some exterior levee segments have vegetation growth on the levee toe that extends out into the bay and/or slough. Repair of levee segments with this vegetation will be avoided by not dredging adjacent to tidal berms more than 50 feet wide, dredging from the center channel to avoid emergent vegetation often found along levee slopes, and avoiding other areas with vegetation.

Dredging in human-made dredger cuts, which are linked directly to the water control infrastructure of the managed wetlands, fish screens, and transect-wide berms will improve drainage issues that have resulted from siltation. Siltation in some instances has restricted flap gates from opening, dammed water in the drainage channel, and clogged trash racks. This reduces the management capabilities and habitat quality on managed wetland units and reduces the effectiveness of state/federal facilities.

Similarly, some of the 16 fish screen structures and the RRDS fish screen experience significant siltation problems. Silt is deposited around these screens, which impedes the operation of the screen and screen-cleaning brushes. Every few years a relatively small amount of material will be removed from the fish screen basins (about 20 to 100 cubic yards each) by dredging. (This amount is included in the total 3 million cubic yards proposed for dredging in the Marsh.) Alternative measures (trying to move silt by hand) have been ineffective.

Dredging around fish screens will be done during low tide to minimize in-water work and minimize turbidity. As the tide returns, the fish screen will be opened to allow turbidity to be drawn into the managed wetland. Dredge spoils will be placed on the crown or landside slope of the exterior levee adjacent to the fish screen. In instances where material cannot be used adjacent to the dredging site, the material may be used on other levees within Suisun Marsh, following the same environmental commitments as identified in the plan.

### 3.4.2. Placing New Riprap in Areas That Were Not Previously Riprapped

The levee system in Suisun Marsh is continually under the pressure of tide stage, wind fetch, eroding currents, and boat-wake damage. With sea level rise and climate change these pressures are expected to increase. Over time, protective vegetated berms and levee toes erode and expose the levee foundation to the erosive forces of wind, water, and logs. Many of the areas that require riprap have been treated, and their continued maintenance is described above. This
activity addresses those areas that currently do not have riprap but that may be determined in the future to require such treatment.

This new activity will place up to 6,000 feet of new riprap over the 30-year plan period on the side slopes of interior water conveyance ditches (i.e., interior levees) and up to 2,000 feet of new riprap on the side slopes of exterior levees on newly exposed areas not previously riprapped. (This is in addition to the replacement of riprap described above.) No more than 200 linear feet of new riprap will be placed annually on the interior levees. Riprap is placed on the levee using a long-reach excavator or a clamshell or dragline dredge. Placement of riprap will be done from June through September. Riprap materials are transported to the site with a 10-wheel dump truck with a capacity of 16 cubic yards or by barge with a 400 cubic yard capacity. For interior levees, this activity is needed occasionally where the velocity of water flowing through an exterior water control structure causes scouring eddies and bank erosion of inter-levee toes.

New riprap will be placed only when it has been determined that the specific conditions of each site would not support other types of erosion control. Riprap will be applied only under the following circumstances:

- Levees exposed to channel velocities that are too high to support vegetation. Depending on soil type, it may be possible for levee material to withstand short durations that exceed 6 fps.
- Channel depth on the face of the levee slope is deeper than 3 feet below Mean Tide Level (MTL, i.e., mid tide) and the levee slope is steeper than 3:1 (H:V); riprap will be applied to reduce erosion potential without consideration for incorporation of vegetation.
- Levee face typically is exposed to vessel wakes year-round and not located in a 5 mph zone; riprap will be applied in areas where erosion persists.
- Fetch length exceeds 1,000 feet in the direction of the predominant southwest to southeast winds during high water conditions (e.g., winter storms, spring tides) or prevailing winds during all other times (typically from the west); riprap will be applied to the upper slope of the levee to dissipate wind-driven waves and reduce erosion potential.

Where new riprap is placed, integrative vegetation also will be applied where it is biologically appropriate.

If new riprap is placed on either interior or exterior levees, BMPs will be implemented to reduce the environmental effect as described below in the Environmental Commitments section.
3.4.3. Constructing New Interior Levees for Improved Water Control and Habitat Management within the Managed Wetland Units

Interior levees are embankments that allow management of water inside exterior levees on the managed wetlands. The interior levees are not exposed to tidal action. The purpose of interior levees is to isolate specific areas within the managed wetland to allow independent water control or different water elevations in those areas. The crown width of these levees is normally 10 feet or less, with a crown height of 3 feet above pond bottom, 1 foot of freeboard, and a side slope of 2:1 on both sides.

Interior levees can be constructed in numerous ways: (1) by excavating a new or existing water conveyance ditch and stacking the excavated material to create an interior levee, (2) recontouring a ponded area and pushing up material with a dozer, (3) placing material with a box scraper to create a levee from high ground or pond bottom areas, or (4) importing materials and placing with an excavator or dozer. Interior levees generally will be constructed during the summer months when managed wetlands are dry. Approximately 400 feet of levee can be constructed per day.

3.5. Preservation Agreement Implementation Fund

The SMPA PAI Fund is proposed to fund certain permitted activities to support mitigation obligations for the CVP and SWP operations. It is funded by DWR and Reclamation as part of the CVP and SWP mitigation for impacts on the Marsh, as described in the Revised SMPA. The PAI Fund will not include activities beyond what is described above for managed wetland activities, but rather will provide a funding mechanism for landowners to perform needed improvements more frequently for improved water management capabilities to fulfill Reclamation and DWR mitigation obligations. As described below, the PAI Fund applies only to specific work activities.

The PAI Fund will be part of a mitigation strategy for the effects of the CVP and SWP operations on water quality in the Marsh. The PAI Fund will contribute to the funding of some activities needed to improve managed wetland facilities operations by establishing a single cost-share funding mechanism that combines the three formerly proposed SMPA Amendment 3 actions into the PAI Fund. The type of improvement determines which cost-share program will apply. These activities will remain as distinct elements under the new PAI Fund, consistent with the objectives and guidelines of each program, cost-share requirements, and regulatory permitting compliance requirements.

The Joint-Use Facility Improvements (JUFI) program will provide funds on a 75/25 cost-share basis for infrastructure improvement to increase efficient and cooperative use of joint-use water delivery systems to managed wetlands. Joint-
use facility structures may include but are not limited to interior levees, water conveyance ditches, water control structures, and permanent pumps. Funded activities include construction of new facilities and improvements to existing facilities.

The PAI Fund includes two programs: the 75/25 cost-share program and a 50/50 cost-share program. The 75/25 cost-share program will provide funds for infrastructure improvements that are necessary for the property to meet the 30-day flood and drain cycle objective for managed wetlands. Reimbursement of approved expenditures is limited to the purchase and installation of new, larger, lowered, or relocated discharge facilities to enable the individual owners to meet the 30-day flood and drain cycle. Funds made available by this program will not be used for regular maintenance or for fish screen construction.

The 50/50 cost-share program will provide funds for management and infrastructure improvements that are necessary to improve leaching and drainage efficiency of individual clubs. Eligible activities include cleaning, widening, deepening, and creating new primary and secondary ditches; adding V-ditches or drainage swales; raising elevations of pond bottom sinks; installing or improving interior water control structures; coring interior levees; offsetting electrical and fuel costs for portable and stationary pumps during spring leaching periods only; and offsetting fish screen electrical costs.

These funds, totaling $3.7 million, could be used for improvements as shown in Table 6 below.

3.6. Protection of Other Habitat Types

The SMP is not specifically intended to restore, protect, or enhance habitats besides existing managed wetlands and properties acquired for tidal wetlands restoration. However, the Principal Agencies recognize the importance of other habitats in the Marsh. As such, when properties are restored, the specific project proponent will protect sensitive habitats that may be located within the bounds of that property. In these instances, the following actions will be implemented as feasible.

- Protect and enhance existing tidal wetlands, vernal pool, riparian, and aquatic habitat functions and values by installing fencing to enable improved grazing management.

- Maintain trees, including nonnative eucalyptus, wherever feasible, which provide limited roosting and nesting habitat for raptors, herons, egrets, and other native species in the Marsh.

- Modify and/or set back existing levees to expand the floodplain and restore natural riparian processes.

- Remove and/or modify barriers to upstream fish movement/migration within the project area.

- Plant native riparian trees and shrubs to increase habitat diversity and structure.

- Identify sources of low–dissolved oxygen (DO) water in sloughs and bays, and where feasible, implement strategies for increasing DO concentrations in receiving waters.

- Increase natural connectivity between the shallow high productivity marsh plain habitat and adjacent nutrient rich channels and sloughs.

Of the restored areas, a certain portion is expected to become tidal aquatic habitat. The percent cover of tidal aquatic habitat within tidal wetlands areas (Rush Ranch, Lower Joice Island, and Hill Slough) in Suisun Marsh was estimated based on existing tidal wetlands, the Integrated Regional Wetland Monitoring Pilot Project (BREACH), and GIS and site visits. The analysis demonstrated that tidal aquatic habitat accounts for an average of approximately 5 to 15% of the total area of established tidal wetlands. Assuming this relationship holds true for future restored tidal wetlands, an increase of 250–1,050 acres of tidal aquatic habitat would be expected to result when the SMP is fully implemented and sites develop into fully functioning tidal marshes.

Over the 30-year SMP implementation period, it is expected that the exact habitat amount provided by restored areas will depend on the existing elevation of the site, sedimentation rates and accretion, and sea level rise. The amount of subtidal aquatic habitat is expected to decrease gradually as sediment accretes and emergent tidal vegetation is established at each restoration site. As this happens, the site will be restored to a tidal wetland. However, the rate of accretion and the rate of sea level rise will dictate the end result, and the actual timeframe for such progression depends on the site-specific conditions, but significant geomorphic
changes are decadal. Locations with large subsidence and low sediment concentrations may never return to emergent marsh and instead remain as open water. Adaptive management, as described below, also will be used to improve restoration designs to achieve desired results.
4. Environmental Commitments

As part of the plan implementation, individual project proponents will incorporate certain environmental commitments and BMPs into specific projects to avoid or minimize potential impacts as applicable. Project proponents and the appropriate agencies also will coordinate planning, engineering, and design phases of the project. The environmental commitments are divided between restoration activities and managed wetland activities. For restoration activities, project proponents are defined as any state, federal, or local agency; landowner; or implementing body of a tidal restoration action in the Marsh. For managed wetland activities, the SMPA Agencies (SRCD, DFG, DWR, and/or Reclamation) are the project proponents and are responsible for implementing the environmental commitments, depending on the activity.

4.1. Restoration Environmental Commitments

The following BMPs and environmental commitments will be implemented during tidal wetland restoration activities. The environmental commitments discussed below apply to the activities described above in Section 3.1, Tidal Wetland Restoration.

4.1.1. Standard Design Features and Construction Practices

In preparing the SMP, the Principal Agencies determined the following design features and construction practices to be potentially feasible and implementable measures to reduce or mitigate certain short-term, construction-related effects. These measures will be implemented at a site-specific level, as appropriate, depending on the location of construction, potential effects of the specific project, and surrounding land uses. The identified measures are:

- Stopping work immediately if a conflict with a utility facility occurs and contacting the affected utility to (1) notify it of the conflict, (2) aid in coordinating repairs to the utility, and (3) coordinate to avoid additional conflicts in the field.

- Constructing structures in accordance with California Building Code and County General Plan Standards to resist seismic effects and to meet the implementation standards outlined in the Solano County General Plan.

- Ensuring that changes within the Suisun Marsh channels will not significantly affect navigation and emergency access by having Rio Vista and Vallejo Coast Guard Stations review plans to assess safety issues associated with changes when there is potential for in-channel work to affect access.
Implementing BMPs to minimize any disease-carrying mosquitoes and threats to public health if it is found that project components pose a threat to public health.

Controlling construction equipment access and placement of fill to maintain acceptable loading based on the shear strength of the foundation material.

Minimizing degradation of wetland habitats where feasible, i.e., work will be conducted from levee crown.

Implementing BMPs and minimization measures to minimize water quality impacts such as temporary turbidity increases. See Erosion and Sediment Control Plan below.

Inspecting all equipment for oil and fuel leaks every day prior to use. Equipment with oil or fuel leaks will not be used within 100 feet of wetlands.

Requiring the construction contractor to remove all trash and construction debris after construction and to implement a revegetation plan for temporarily disturbed vegetation in the construction zones.

Maintaining waste facilities. Waste facilities include concrete wash-out facilities, chemical toilets, and hydraulic fluid containers. Waste will be removed to a proper disposal site.

4.1.2. Access Point/Staging Areas

Project proponents will establish staging areas for equipment storage and maintenance, construction materials, fuels, lubricants, solvents, and other possible contaminants in coordination with resource agencies. Practices and procedures for construction activities along city and county streets will be consistent with the policies of the affected local jurisdiction.

Staging areas will have a stabilized entrance and exit and will be located at least 100 feet from bodies of water unless site-specific circumstances do not provide such a setback, in which case the maximum setback possible will be used. If an off-road site is chosen, qualified biological and cultural resources personnel will survey the selected site to verify that no sensitive resources would be disturbed by staging activities. If sensitive resources are found, an appropriate buffer zone will be staked and flagged to avoid impacts. If impacts on sensitive resources cannot be avoided, the site will not be used. An alternate site will be selected.

Where possible, no equipment refueling or fuel storage will take place within 100 feet of a body of water. Vehicle traffic will be confined to existing roads and the proposed access route. Ingress and egress points will be clearly identified in the field using orange construction fence. Work will not be conducted outside the designated work area.
4.1.3. Erosion and Sediment Control Plan

For projects that could result in substantial erosion, project proponents will prepare and implement an erosion and sediment control plan to control short-term and long-term erosion and sedimentation effects and to restore soils and vegetation in areas affected by construction activities. The plan will include all the necessary local jurisdiction requirements regarding erosion control and will implement BMPs for erosion and sediment control as required.

An erosion control plan will be developed to ensure that during rain events construction activities do not increase the levels of erosion and sedimentation. This plan will include the use of erosion control materials (baffles, fiber rolls, or hay bales; temporary containment berms) and erosion control measures such as straw application or hydroseeding with native grasses on disturbed slopes, and floating sediment booms and/or curtains to minimize any impacts that may occur from increased mobilization of sediments.

4.1.4. Stormwater Pollution Prevention Plan

For projects that involve grading or disturbance of more than 1 acre, a stormwater pollution prevention plan (SWPPP) will be developed by a qualified engineer or erosion control specialist and implemented prior to construction. The objectives of the SWPPP will be to (1) identify pollutant sources associated with construction activity and project operations that may affect the quality of stormwater and (2) identify, construct, and implement stormwater pollution prevention measures to reduce pollutants in stormwater discharges during and after construction. The project proponents and/or their contractor(s) will develop and implement a spill prevention and control plan as part of the SWPPP to minimize effects of spills of hazardous, toxic, or petroleum substances during construction of the project. Implementation of this measure will comply with state and federal water quality regulations. The SWPPP will be kept on site during construction activity and during operation of the project and will be made available upon request to representatives of the Regional Water Quality Control Board (Regional Water Board). The SWPPP will include but is not limited to:

- A description of potential pollutants to stormwater from erosion.
- Management of dredged sediments and hazardous materials present on site during construction (including vehicle and equipment fuels).
- Details of how the sediment and erosion control practices comply with state and federal water quality regulations.
- A description of potential pollutants to stormwater resulting from operation of the project.
4.1.5. Noise Compliance

The project proponents and/or their contractors will comply with local noise regulations when construction activities occur near residences by limiting construction to the hours specified by Solano County. It is assumed that construction activities will occur during normal working hours, between 7:00 a.m. and 6:00 p.m., Monday through Friday, and between 8:00 a.m. and 5:00 p.m., Saturday and Sunday.

Additionally, when it is determined through site-specific analysis that construction has the potential to occur near residences, noise-reduction practices listed below will be implemented.

- Use electrically powered equipment instead of internal combustion equipment where feasible.
- Locate staging and stockpile areas and supply and construction vehicle routes as far away from sensitive receptors as possible.
- Establish and enforce construction site and haul road speed limits.
- Restrict the use of bells, whistles, alarms, and horns to safety warning purposes.
- Design equipment to conform to local noise standards.
- Locate equipment as far from sensitive receptors as possible.
- Equip all construction vehicles and equipment with appropriate mufflers and air inlet silencers.
- Restrict hours of construction to periods permitted by local ordinances.
- Locate redirected roadways away from sensitive receptors.

4.1.6. Traffic and Navigation Control Plan and Emergency Access Plan

For projects that would substantially affect traffic or navigation patterns, or could result in hazardous road or waterway conditions, the project proponents, in coordination with affected jurisdictions, will develop and implement a traffic and navigation control plan, which will include an emergency access plan to reduce construction-related effects on the local roadway and waterway systems and to avoid hazardous traffic and circulation patterns during the construction period. All construction activities will follow the standard construction specifications and procedures of the appropriate jurisdictions, and will avoid major construction activities on days known or expected to have a significant increase in traffic as a result of events in the Marsh.

The traffic and navigation control plan will include an emergency access plan that provides access into and adjacent to the construction zone for emergency vehicles. The emergency access plan, which requires coordination with
emergency service providers such as the Coast Guard before construction, will require effective traffic and navigation direction, substantially reducing the potential for disruptions to response routes.

The traffic and navigation control plan will include but not be limited to the following actions, depending on site-specific conditions.

- Coordinating with the affected jurisdictions on construction hours of operation.
- Following guidelines of the local jurisdiction for road closures caused by construction activities.
- Installing traffic control devices as specified in the California Department of Transportation’s (Caltrans’) *Manual of Traffic Controls for Construction and Maintenance Works Zones* (2004).
- Notifying the public of road closures in the immediate vicinity of the open trenches in the construction zone and of temporary closures of recreation trails.
- Posting signs that conform to the California Uniform State Waterway Marking System upstream and downstream of the dredge areas to warn boaters of work.
- Providing access to driveways and private roads outside the immediate construction zone.
- Coordinating with Solano County to monitor and repair road damage to levee roads and any other roads damaged during construction to the extent allowed by law, depending on the specific project proponent. A memorandum of understanding (MOU) may be implemented for specific restoration projects and could include the following as suggested by Solano County:
  - The restoration project will be responsible for the cost of maintaining, repairing, paving and/or reconstructing roads affected during construction, operation, and maintenance of the restoration project.
  - Repairs will be implemented to comply with the current County Road Improvement Standards, except that repairs to damaged paved sections may be made within 5 inches of asphalt concrete at the discretion of the County, while repairs to damaged gravel sections of road will replace the preexisting depth of aggregate base but not less than 12 inches in depth.
- Coordinating with the Union Pacific Railroad prior to beginning any work within the right-of-way of a rail line to ensure that the integrity of the rail line is maintained and to minimize disruptions to service.
- Coordinating with emergency service providers before construction to develop an emergency access plan for emergency vehicles into and adjacent to the construction zone; the emergency access plan will require effective traffic direction, substantially reducing the potential for disruptions to response routes.
4.1.7. **Recreation Best Management Practices**

The project proponents will implement measures related to recreation and recreation facilities to decrease impacts.

- Avoid nesting habitats and other sensitive areas, such as important roosting and foraging sites during critical nesting periods.

Temporary impacts on boating access may be minimized by these measures.

- Not allowing construction to occur during major summer holiday periods.
- Maintaining boat access to prime areas.
- Providing public information regarding alternate access.
- Posting warning signs and buoys in channels, upstream of and downstream of all construction equipment, sites, and activities during construction.
- Posting signs describing alternate boating routes in convenient locations when boating access is restricted.
- Minimizing water-level fluctuation during construction.

4.1.8. **Mosquito Abatement Best Management Practices**

As described in Section 7.8, Public Health and Environmental Hazards, the Solano County Mosquito Abatement District (SCMAD) is concerned that tidal restoration has the potential to increase mosquito production in the Marsh. However, tidal restoration will be designed to minimize such effects. To further reduce the potential for this effect to occur, SCMAD has recommended several measures to reduce the potential for the production of, and subsequent spread of diseases carried by, mosquitoes. Specific project proponents will develop site-specific plans to address mosquito production for each restoration activity based on the following recommendations, which will be implemented prior to removal or breaching of any levee or water control structure.

- Develop a management program consistent with Marsh-wide management actions for the control of mosquitoes.
- If necessary, obtain an engineering survey to locate depressions that would retain tidal water and design site restoration to promote water drainage.

4.1.9. **Hazardous Materials Management Plan**

A hazardous materials spill plan will be developed prior to construction of each action. The plan will describe the actions that will be taken in the event of a spill. The plan also will incorporate preventive measures to be implemented (such as vehicle and equipment staging, cleaning, maintenance, and refueling) and contaminant (including fuel) management and storage. In the event of a
contaminant spill, work at the site immediately will cease until the contractor has contained and mitigated the spill. The contractor will immediately prevent further contamination, notify appropriate authorities, and mitigate damage as appropriate. Adequate spill containment materials, such as oil diapers and hydrocarbon cleanup kits, will be available on site at all times. Containers for storage, transportation, and disposal of contaminated absorbent materials will be provided on the project site.

The project proponents and their contractors will not use any hazardous material in excess of reportable quantities, as specified in Title 40 Code of Federal Regulations (CFR) Part 355, Subpart J, Section 355.50, unless approved in advance by the Office of Emergency Services (OES), and will provide to the OES in the annual compliance report a list of hazardous materials contained at a project site in reportable quantities. The reporting of hazardous materials in excess of reportable quantities of Title 40 CFR Part 355 is required annually to Solano County Environmental Health Services Division as the Solano County Certified Unified Program Agency (CUPA).

For large-scale projects, the project proponents will prepare a risk management plan (RMP). The RMP will be submitted to the U.S. Environmental Protection Agency (EPA) and will reflect the comments of the Solano County CUPA. An RMP addresses acutely hazardous materials such as chlorine gas, ammonia gas, hydrogen chloride, flammable gases. This document is required to be submitted to both the EPA and Solano County Environmental Health Services Division as the CUPA. The plan will describe procedures, protective equipment requirements, and training and contain a checklist. At least 60 days before the start of construction, or a lesser period of time mutually agreed upon, the project proponents will provide the final RMP and the safety plan to the Certified Property Manager (CPM).

4.1.10. Air Quality Best Management Practices

The following control practices will be used to offset any air quality issues that may arise (Bay Area Air Quality Management District 1999).

**Basic Control Measures**

The following controls will be implemented at all construction sites.

- Treat all graded surfaces to prevent nuisances from dust or spillage on roads or adjacent properties.
Enhanced Control Measures

The following measures will be implemented at construction sites greater than 4 acres in area.

- Hydroseed with native or noninvasive species appropriate to that specific location or apply (nontoxic) soil stabilizers to inactive construction areas (previously graded areas inactive for 10 days or more).
- Limit traffic speeds on unpaved roads to 15 mph.
- Install sandbags or other erosion control measures to prevent silt runoff to public roadways.
- Replant vegetation with native or noninvasive species appropriate to that specific location in disturbed areas as quickly as possible.

Additional Air Quality Best Management Practices

In addition to the above BMPs, the following measures will be required in order to further reduce construction emissions:

- Maintain properly tuned engines.
- Minimize the idling time of diesel-powered construction equipment to 2 minutes.
- Use alternative-powered (e.g., hybrid, compressed natural gas, biodiesel, electric) construction equipment.
- Use add-on control devices such as diesel oxidation catalysts or particulate filters.
- Require all contractors to use equipment that meets California Air Resources Board’s most recent certification standard for off-road heavy-duty diesel engines.

4.1.11. Visual/Aesthetic Best Management Practices

For projects that have the potential to affect views or create a new source of light or glare, project proponents will identify sensitive view receptors for site-specific analysis and ensure that contractors minimize fugitive light from portable sources used for nighttime operations. Also, a visual barrier will be installed to prevent light spill from truck headlights in areas with sensitive view receptors.

4.1.12. Inadvertent Discovery of Cultural Resources

Federal and state laws and regulations outline the courses of action required in the event of inadvertent discoveries of cultural resources, including human remains. Section 106 of the National Historic Preservation Act (NHPA) allows
federal agencies to plan for post-Section 106 review, or inadvertent, discoveries of cultural resources prior to authorization of a federal action or undertaking (36 CFR 800.13[a]). One avenue for planning is through a programmatic agreement (PA) (see 36 CFR 800.13[a][2]). Such PAs must define the parties responsible for action in the event of cultural resource discoveries, communication protocols, response times, and specific action items. The cultural resources analysis in the SMP EIS/EIR identifies a PA as a critical element in mitigating significant effects on cultural resources; the PA will include provisions for inadvertent discoveries.

Federal and state laws and regulations impose additional requirements specific to the discovery of human remains and associated artifacts. On federal or tribal land, human remains discoveries are subject to the Native American Grave Protection and Repatriation Act (NAGPRA). Additionally, Reclamation has specific policies for the implementation of the NAGPRA provisions (Reclamation Directives and Standards LND 07-01). For human remains discoveries on non-federal land, the requirements of the California Public Resources Code and Health and Safety Code apply, as described below. In the event that human remains are discovered inadvertently during ground-disturbing activities, the lead state or federal agency will implement the following measures. These measures also will be discussed, with explicit treatment of roles and responsibilities under the various applicable regulations, in the PA referenced previously.

- The contractor immediately will cease work within 100 feet of the find. All construction personnel will leave the area. Vehicles and equipment will be left in place until a qualified archaeologist identifies a safe path out of the area. The on-site supervisor will flag or otherwise mark the location of the find and keep all traffic away from the resource. The on-site supervisor immediately will notify the lead state or federal agency of the find.

- The lead federal agency is responsible for compliance with NAGPRA (43 CFR 10) if inadvertent discovery of Native American remains occurs on federal lands. The lead federal agency is responsible for compliance with state laws relating to the disposition of Native American burials (Public Resources Code [PRC] 5097 and California Health and Safety Code 7050.5[b]) for human remains discoveries on non-federal lands.

- If human remains of Native American origin are discovered during ground-disturbing activities on non-federal land, the lead state or federal agency must comply with state laws relating to the disposition of Native American burials, which fall within the jurisdiction of the Native American Heritage Commission (NAHC) (PRC 5097). If human remains are discovered or recognized in any location other than a dedicated cemetery, the lead state or federal agency will not allow further excavation or disturbance of the site or any nearby area reasonably suspected to overlie adjacent human remains until:
  - the Solano County coroner has been informed and has determined that no investigation of the cause of death is required; and
  - if the remains are of Native American origin,
- the descendants of the deceased Native Americans have made a recommendation to the landowner or the person responsible for the excavation work for means of treating or disposing of, with appropriate dignity, the human remains and any associated grave goods as provided in PRC 5097.98; or
- the NAHC was unable to identify a descendant or the descendant failed to make a recommendation within 48 hours after being notified by the NAHC.

- If any previously unknown historic or archeological artifacts are discovered while accomplishing the authorized work, the landowner must stop work immediately and notify the Corps. The activity is not authorized until the requirements of Section 106 of the NHPA have been satisfied.
- Work is not authorized within 100 feet of archeological site CAL-SOL-13.

4.1.13. Biological Resources
Best Management Practices

The following section outlines the potential BMPs that will be implemented to avoid or minimize impacts on biological resources. The BMPs that are implemented for each specific project will depend on the project location, potential to adversely affect biological resources, and guidance and requirements set forth by resource agencies through informal and formal consultations. Environmental commitments, including an erosion and sediment control plan, SWPPP, hazardous materials management plan, spoils disposal plan, and environmental training content will be reviewed by NMFS, USFWS, and DFG 30 days prior to construction activities commencing at a restoration site. Any adverse effects on special-status species, critical habitat, or essential fish habitat (EFH) attributable to construction activities may require implementation of additional avoidance or mitigation measures. NMFS, USFWS, and DFG will be consulted, and additional avoidance and mitigation measures may be implemented on a site-specific basis.

General

- No firearms (except for federal, state, or local law enforcement officers and security personnel) will be permitted at the project site to avoid harassment, killing, or injuring of wildlife.
- No pets will be permitted at the project site to avoid harassment, killing, or injuring of wildlife.
- Native vegetation trimmed or removed on the project site will be stockpiled during work. After construction activities, removal of temporary mats and construction-related materials, and application of native seed mix have been completed, stockpiled native vegetation will be reapplied over temporarily disturbed wetlands to provide temporary soil protection and as a seed source.
Where vegetation removal is required, work will be conducted using hand-held tools to enable wildlife to escape. If any areas with pickleweed or vegetation within 50 feet of the edge of pickleweed need to be cleared for project activities, vegetation shall be removed only with non-mechanized hand tools (i.e., trowel, hoe, rake, and shovel). No motorized equipment, including weed whackers and lawn mowers, shall be used to remove this vegetation. Vegetation shall be removed under the supervision of a qualified biologist approved by DFG and USFWS. If a mouse of any species is observed within the areas being removed of vegetation, DFG and USFWS shall be notified. Vegetation removal may begin when no mice are observed and shall start at the edge farthest from the salt marsh or the poorest habitat and work its way toward the salt marsh or the better salt marsh habitat.

Removal of vegetation in wetland habitat will be conducted with a qualified biological monitor present. This monitor will watch for special-status wildlife species and temporarily stop work if special-status species are encountered. Wildlife will be allowed to escape before work is resumed. Monitors with the appropriate qualifications to handle special-status species will be allowed to move special-status species to safe locations as permitted by their authorizations.

Temporarily affected wetlands will be restored by removing construction-related debris and trash. Affected areas will be seeded with a seed mix of local native wetland species.

Worker Training

Project proponents will provide training to field management and construction personnel on the importance of protecting environmental resources. Communication efforts and training will take place during preconstruction meetings so that construction personnel are aware of their responsibilities and the importance of compliance.

Construction personnel will be educated on the types of sensitive resources located in the project area and the measures required to avoid impacts on these resources. Materials covered in the training program will include environmental rules and regulations for the specific project and requirements for limiting activities to the construction right-of-way and avoiding demarcated sensitive resources areas. Training seminars will educate construction supervisors and managers on:

- The need for resource avoidance and protection.
- Construction drawing format and interpretation.
- Staking methods to protect resources.
- The construction process.
- Roles and responsibilities.
- Project management structure and contacts.
Environmental commitments.

Emergency procedures.

If new construction personnel are added to the project, the contractor will ensure the personnel receive the mandatory training before starting work. A representative will be appointed during the employee education program to be the contact for any employee or contractor who might inadvertently kill or injure a listed species or who finds a dead, injured, or entrapped individual. The representative’s name and telephone number will be provided to the USFWS before the initiation of ground disturbance.

Special-Status Plant Species Protection

A complete botanical survey of restoration areas will be completed using the USFWS’s Guidelines for Conducting and Reporting Botanical Inventories for Federally Listed, Proposed and Candidate Plants (September 23, 1996) (U.S. Fish and Wildlife Service 1996) and DFG’s Protocols for Surveying and Evaluating Impacts to Special Status Native Plant Populations and Natural Communities (November 24, 2009) (California Department of Fish and Game 2009) and/or DFG's Guidelines for Assessing the Effects of Proposed Projects on Rare, Threatened, and Endangered Plants and Natural Communities (May 8, 2000).

Special-status plant surveys required for project-specific permit compliance will be conducted within 1 year prior to initiating construction. The purpose of these surveys will be to verify the locations of special-status plants identified in previous surveys are extant, identify any new special-status plant occurrences, and cover any portions of the project area not previously identified. The extent of mitigation of direct loss of or indirect impacts on special-status plants will be based on these survey results.

Locations of special-status plants in proposed construction areas will be recorded using a global positioning system (GPS) unit and flagged.

If initial screening by a qualified biologist identifies the potential for special-status plant species to be directly or indirectly affected by a specific project, the biologist will establish an adequate buffer area to exclude activities that would directly remove or alter the habitat of an identified special-status plant population or result in indirect adverse effects on the species.

Access may be restricted around restoration sites where necessary to protect special-status plant populations through appropriate management plans and the design of the tidal marsh restoration. This may include signage, buffers, seasonal restrictions, and design or no access, depending on the sensitive species in question.

The project proponents will oversee installation of a temporary, plastic mesh–type construction fence (Tensor Polygrid or equivalent) at least 1.2 meters (4 feet) tall around any established buffer areas to prevent encroachment by construction vehicles and personnel. A qualified biologist will determine the exact location of the fencing. The fencing will be strung
tightly on posts set at maximum intervals of 3 meters (10 feet) and will be checked and maintained weekly until all construction is complete. The buffer zone established by the fencing will be marked by a sign stating:

This is habitat of [the special-status species being protected], a [identify the species’ status] plant species, and must not be disturbed. This species is protected by [the Endangered Species Act of 1973, as amended/California Endangered Species Act/California Native Plant Protection Act]. Violators are subject to prosecution, fines, and imprisonment.

No construction activity, including grading, will be allowed until this condition is satisfied.

- No grading, clearing, storage of equipment or machinery, or other disturbance or activity will occur until all temporary construction fencing has been inspected and approved by the qualified biologist.

- Where feasible, for stump-sprouting vegetation, construction will limit removal of woody vegetation by trimming vegetation to approximately 1 foot above ground level.

Special-Status Wildlife Species Protection

If individuals of listed wildlife species may be present and subject to potential injury or mortality from construction activities, a qualified biologist will conduct a preconstruction survey. Minimum qualifications for the qualified biologist will be a 4-year college degree in biology or related field and 2 years of professional experience in the application of standard survey, capture, and handling methods for the species of concern. However, in the case of fully protected species, no capture or handling will be done. Fully protected wildlife species are listed in Section 6.3, Wildlife. Any special-status mammal, bird, or other species observed during surveys will be reported to DFG so the observations can be added to the California Natural Diversity Database.

Mammals

Only two special-status mammal species occur in the Marsh, SMHM and Suisun shrew. Suisun shrews use habitat similar to SMHM, so any measures implemented to protect SMHM would apply to shrews. The following measures will be implemented:

- A USFWS-approved biologist, with previous SMHM monitoring and surveying experience, will identify suitable salt marsh habitat for the mouse prior to project initiation.

- Disturbance to wetland vegetation (i.e., pickleweed [Salicornia spp.]) will be avoided to the extent feasible in order to reduce potential impacts on SMHM habitat. If wetland vegetation (i.e., pickleweed [Salicornia spp.]) cannot be avoided, it will be removed by hand (and/or by another USFWS- and DFG-approved method). The USFWS-approved biologist will be on site to monitor all wetland vegetation removal activities.

- The upper 6 inches of soil excavated within SMHM habitat will be stockpiled separately and replaced on top of the backfilled material.
Vegetation will be removed using hand tools (and/or by another USFWS- and DFG-approved method).

- In construction and staging areas where habitat is to be disturbed, vegetation must be cleared to bare ground or stubble no higher than 1 inch.

- Work will be scheduled to avoid extreme high tides (6.5 feet or above, as measured at the Golden Gate Bridge) when there is potential for SMHM to move to higher, drier grounds. All equipment will be staged on existing roadways away from the project site when not in use.

- To prevent SMHM from moving through the project site during construction, temporary exclusion fencing will be placed around a defined work area before construction activities start and immediately after vegetation removal. The fence should be made of a material that does not allow SMHM to pass through or over, and the bottom should be buried to a depth of 2 inches so that mice cannot crawl under the fence. Any supports for the SMHM exclusion fencing must be placed on the inside of the project area.

- Prior to the start of daily construction activities during initial ground disturbance, the USFWS-approved biological monitor will inspect the SMHM-proof boundary fence to ensure that it has no holes or rips and the base is still buried. The fenced area also will be inspected to ensure that no mice are trapped in it. Any mice found along and outside the fence will be closely monitored until they move away from the construction area.

- If a SMHM is discovered, construction activities will cease in the immediate vicinity of the individual until DFG and USFWS are contacted and the individual has been allowed to leave the construction area.

- A DFG- and USFWS-approved biologist with previous SMHM experience will be on site during construction activities occurring in wetlands. The biologist will document compliance with the project permit conditions and avoidance and conservation measures. The biologist has the authority to stop project activities if any of the requirements associated with these measures is not being fulfilled. If the biologist has requested work stoppage because of take of any of the listed species, the USFWS and DFG will be notified within 1 day by email or telephone.

**Birds**

The project proponents will perform preconstruction surveys to determine whether nesting birds, including migratory birds, raptors, and special-status bird species, are present within or immediately adjacent to the project sites and associated staging and storage areas if activities would occur during active nesting periods. Bird species using the managed wetland habitat include waterfowl, shorebirds, Suisun song sparrow, Suisun common yellowthroat, and several other resident and migratory songbirds.

- The project proponents will remove all woody and herbaceous vegetation from construction areas (earthwork areas) during the nonbreeding season (September 1–February 1) to minimize effects on nesting birds.
During the breeding season, all vegetation subject to impact will be maintained to a height of approximately 6 inches to minimize the potential for nesting.

If construction occurs during the breeding season and not all affected vegetation has been removed, a qualified biologist will survey the construction area for active nests and young migratory birds immediately before construction.

If active nests or migratory birds are found within the boundaries of the construction area, the project proponents will develop appropriate measures and coordinate with DFG to determine an acceptable buffer width.

Inactive migratory bird nests (excluding raptors) located outside the construction areas will be preserved. If an inactive migratory bird nest is located in the area of effect, it will be removed before the start of the breeding season (approximately February 1).

Impacts on great blue heron rookeries will be avoided; mature trees will not be removed, and nearby work will occur outside the nesting season.

Raptors

Preconstruction surveys will be performed before and during the raptor nesting season (bimonthly, i.e., two times per month) to identify existing nests that may be used during the nesting season.

Raptors may nest from later winter through mid-summer; therefore, multiple nesting season surveys will performed.

DFG will be notified of all raptor nests located during the preconstruction surveys. If a raptor nest is located within the recommended buffer, the project proponents will coordinate with DFG to determine an acceptable buffer width.

If an active raptor nest is found outside the construction areas, a buffer zone will be created around the nest tree. For special-status species, a larger buffer will be required (e.g., 0.5-mile Swainson’s hawk buffer). The project proponents will coordinate with DFG prior to project implementation to determine the species-specific buffer widths.

**California Clapper Rail and California Black Rail**

If construction activities are necessary during the breeding season, preconstruction surveys for California clapper rail and black rail will be conducted at and adjacent to areas of potential tidal and managed wetlands habitat for California clapper rail and black rail. The surveys will focus on potential habitat that may be disturbed by construction activities during the breeding season to ensure that these species are not nesting in these locations. Survey methods will follow the protocols used by DFG during previous rail surveys in Suisun Marsh (California Department of Fish and Game 2007). The specific project proponent will implement the following survey protocols.

Surveys should be initiated sometime between January 15 and February 1. A minimum of four surveys should be conducted. The survey dates should
be spaced at least 2 to 3 weeks apart and should cover the time period from the date of the first survey through the end of March or mid-April. This will allow the surveys to encompass the time period when the highest frequency of calls is likely to occur.

- Listening stations will be established at 150-meter intervals along roads, trails, and levees that will be affected by plan implementation.
- California clapper rail and California black rail vocalization recordings will be played at each station.
- For California clapper rails, each listening station will be occupied for a period of 10 minutes, followed by 1 minute of playing California clapper rail vocalization recordings, then followed by an additional minute of listening.
- For black rails, each listening station will be occupied for 1 minute of passive listening, 1 minute of “grr” calls followed by 30 seconds of “ki-ki-krrr” calls, then followed by another 3.5 minutes or passive listening.
- Surveys will be conducted at sunrise and sunset.
- Sunrise surveys will begin 60 minutes before sunrise and conclude 75 minutes after sunrise (or until presence is detected).
- Sunset surveys will begin 75 minutes before sunset and conclude 60 minutes after sunset (or until presence is detected).
- Surveys will not be conducted when tides are greater than 4.5 National Geodetic Vertical Datum (NGVD) or when sloughs and marshes are more than bankfull.
- California clapper rail and California black rail vocalizations will be recorded. A GPS receiver will be used to identify call location and distance. The call type, location, distance, and time will be recorded on a data sheet.

If California clapper rail or black rail is present in the immediate construction area, the following measures will apply during construction activities.

- To avoid (or minimize) the loss of individual California clapper rails or black rails, activities within or adjacent to California clapper rail or black rail habitat will not occur within 2 hours before or after extreme high tides (6.5 feet or above, as measured at the Golden Gate Bridge), when the marsh plain is inundated, because protective cover for California clapper rails is limited and activities could prevent them from reaching available cover.
- To avoid (or minimize) the loss of individual California clapper rails or black rails, activities within or adjacent to tidal marsh areas will be avoided during the California clapper rail breeding season from February 1 through August 31 each year unless surveys are conducted to determine California clapper rail locations and California clapper rail and black rail territories can be avoided. Figure 3 shows the areas of known clapper rail breeding habitat.
- If breeding California clapper rails or black rails are determined to be present, activities will not occur within 700 feet of an identified calling center. If the intervening distance across a major slough channel or across a substantial barrier between the California clapper rail calling center and any
Figure 3
California Clapper Rail Habitat in Suisun Marsh
activity area is greater than 200 feet, it may proceed at that location within the breeding season.

- **Exception:** Only inspection, maintenance, research, or monitoring activities may be performed during the California clapper rail or black rail breeding season in areas within or adjacent to California clapper rail breeding habitat with approval of the USFWS and DFG under the supervision of a qualified biologist.

**California Least Tern**

- No activities will be performed within 300 feet of an active least tern nest during the least tern breeding season, April 15 to August 15 (or as determined through surveys).

- **Exception:** Only inspection, maintenance, research, or monitoring activities may be performed during the least tern breeding season in areas within or adjacent to least tern breeding habitat with approval of the USFWS and DFG under the supervision of a qualified biologist.

**Biological Monitoring**

- The project proponents will provide a biologist/environmental monitor who will be responsible for monitoring implementation of the conditions in the state and federal permits (CWA Section 401, 402, and 404; ESA Section 7; Fish and Game Code Section 1602 and/or 2050; project plans [SWPPP]; and EIS/EIR mitigation measures).

- The biologist/environmental monitor will determine the location of environmentally sensitive areas adjacent to each construction site based on mapping of existing land cover types and special-status plant species. If such maps are not available, the biologist/environmental monitor will map and quantify the land cover types and special-status plant populations in the proposed project footprint prior to construction.

- To avoid construction-phase disturbance to sensitive habitats immediately adjacent to the project area, the monitor will identify the boundaries of sensitive habitats and add at least a 100-foot buffer, where feasible, using orange construction barrier fencing. The fencing will be mapped on the project designs. Erosion-control fencing also will be placed at the edges of construction where the construction activities are upslope of wetlands and channels to prevent washing sediment off site. The sensitive habitat and erosion-control fencing will be installed before any construction activities begin and will be maintained throughout the construction period.

- The biologist/environmental monitor will ensure the avoidance of all sensitive habitat areas outside direct project footprints, including patches of tidal wetland along channel banks, during dredging operations, to the extent practical.

- Plants for revegetation will come primarily from natural recruitment. Plants imported to the restoration areas will come from local stock, and to the extent
possible, local nurseries. Only native plants will be used for restoration efforts.

**Construction Period Restrictions**

Timing of restoration construction activities will depend on the type of activity, presence or absence of sensitive resources, tides, and/or water management in wetlands. In general, landside work will occur between July and September. In-water activities will be conducted during the months of August through November (Figure 4). Working outside this window will require additional approvals from the resource agencies. Other timing restrictions may be necessary during the hunting season, such as limiting work to days other than Saturday, Sunday, and Wednesday.

### 4.1.14. Nonnative Plant Control

The project proponents will include the following measures in the project construction specifications to minimize the potential for the introduction of new noxious weeds and the spread of weeds previously documented in the project area.

- Use certified, weed-free, imported erosion control materials (or rice straw in upland areas).
- Coordinate with the county agricultural commissioner and land management agencies to ensure that the appropriate BMPs are implemented.
- Educate construction supervisors and managers on weed identification and the importance of controlling and preventing the spread of noxious weeds.
- Clean equipment at designated wash stations after leaving noxious weed infestation areas.
- Treat isolated infestations of noxious weeds identified in the project area with approved eradication methods at an appropriate time to prevent further formation of seed, and destroy viable plant parts and seed.
- Minimize surface disturbance to the greatest extent possible.
- Use certified weed-free native mixes for any restoration planting or seeding as may be necessary, as provided in the revegetation plan developed in cooperation with DFG. Mulch with certified weed-free mulch. Rice straw may be used to mulch upland areas.
- Use native, noninvasive species or nonpersistent hybrids in erosion control plantings to stabilize site conditions and prevent invasive species from colonizing.

*Work Activity Windows for Sensitive Species*
4.2. Managed Wetland Activities
Environmental Commitments

The SMPA agencies and private landowners have been maintaining property and/or facilities in the Marsh for more than 3 decades and have operated in compliance with existing BOs from USFWS and NMFS. Implementation of the SMP will include continuation of monitoring, fish screening, and other ongoing requirements and programs. Implementation of the SMP will include submitting biological assessments to USFWS and NMFS. Terms and conditions of the revised BOs will be followed. Any adverse effects on special-status species, critical habitat, or essential fish habitat (EFH) will be addressed by the project proponent, and any additional measures will be followed in compliance with California Endangered Species Act, ESA, and EFH authorizations.

4.2.1. Standard Design Features and Construction Practices

- When possible, drain pipes will be relocated to drain into larger receiving sloughs with good tidal circulation to avoid and minimize the degradation of water quality in receiving waters.

- All new and/or replacement drain pipes will be located on the largest possible sloughs, or sloughs with the highest levels of tidal circulation possible, to minimize or lessen the possibility of degraded water quality conditions.

- Management options, including vegetation management and diversion timing and location, will be pursued to avoid and minimize occurrence of low-DO water conditions in managed wetlands.

- New exterior drain structures will be installed where the discharge channel already exists. The new drain will not be placed on emergent vegetation. The pipe will be installed at low tide. No in-water work is authorized.

- Landowners importing any material besides rock material from outside the Suisun Marsh must contact the Regional Water Board before importation. Landowners must obtain the Regional Water Board’s concurrence that the imported material is acceptable before use.

- Material excavated from existing spreader ditches and creation of new spreader ditches may be sidecast adjacent to the ditch. Excavated material will be no more than 12 inches in height.

- Exterior pipes will be placed below the depth of emergent vegetation.

- Pipe replacement as well as repair, replacement, or installation of exterior water control structures will not change the existing use or diversion capacity.

- All pipes will be pre-assembled before installation to minimize work time.
All material will remain on the crown or interior side of the levee during the repair of exterior existing levees, the coring of existing exterior levees, and the installation of drain pumps and platforms.

All bulkheads will be in place prior to backfilling the bulkhead during installation, repair, or re-installation of water control structures.

Installation of drain pumps and platforms will be done entirely within the managed wetland; although discharge pipes will comply with permit terms and conditions for exterior discharge pipe installation.

All work to be performed on the exterior side of levees will commence and be completed within a 6-hour period, from 3 hours prior to low tide to 3 hours after low tide.

Construction equipment used for projects will be checked each day prior to work and, if necessary, action will be taken to prevent fluid leaks. If leaks occur during work, the Corps, its permittee, or the contractor will contain the spill and remove the affected soils.

All contractors must have a supply of erosion and pollution control materials on site to facilitate a quick response to unanticipated storm events or emergencies.

No in-water work will occur during the repair of existing exterior levees; the coring of existing levees; pipe replacement at the exterior flood or dual-purpose gate; pipe replacement at the existing exterior drain gate; installation, repair, or re-installation of water control bulkheads; installation of drain pumps and platforms; or installation of new exterior drain structures.

Emergent vegetation will not be disturbed during the following activities: repair of existing exterior levees, replacement of existing riprap on exterior levee, or installation of the new exterior drain structure.

No fresh concrete, cement, silts, clay, soil, or other materials will be discharged to Marsh waters.

4.2.2. Reporting Requirements

Proposed work reports must be submitted to the Corps, NMFS, State Lands Commission, and Regional Water Board by the first day of each month. When the first day falls on a weekend, the report will be due the following Monday.

The SRCD will prepare an annual report that summarizes the amounts and locations of activities performed. This report will be submitted to the Corps, EPA, NMFS, USFWS, State Lands Commission, and the Regional Water Board. This report must include an estimate regarding temporarily affected wetlands and describe any additional minimization methods (i.e., replacing a metal pipe with HDPE pipe to lessen future maintenance needs).

The Corps and applicant will provide a written annual report to NMFS by December 31 of each year. The report will be submitted to the NMFS Santa
Rosa Area Office, Attention: Supervisor of Protected Resources Division,  
777 Sonoma Avenue, Room 325, Santa Rosa, California 95404-6528. The report will contain, at a minimum, the following information.

i. **Project-related activities**—The report will include the type, size, and location of specific actions (on exterior pipe replacement and installation and riprap placement) undertaken; dates when specific actions began and were completed; a description of BMPs implemented to minimize project effects; photographs taken before, during, and after the activity from photo reference points; and a discussion of specific project performance or efficacy.

ii. **Unanticipated project effects**—The report will include a discussion of any unanticipated project effects or unanticipated levels of project effects on salmonids, green sturgeon, and/or critical habitat and a description of any and all measures taken to minimize those unanticipated effects as well as a statement regarding whether the unanticipated effects had any effect on ESA-listed fish or critical habitat.

iii. **Gate closures and diversion curtailment**—The report will summarize compliance monitoring for gate closures and diversion curtailments.

iv. **Observations of salmonids and green sturgeon**—The report will document observations of any salmonids or green sturgeon occurring in the action area during project actions.

A summary of the results of water quality monitoring or evaluation of the wetland management operational modifications used is no longer required. This information was previously provided by SRCD and DFG in 2008, 2009, and 2010 to NMFS.

### 4.2.3. Riprap

Riprap replacement may occur in the minimum amount necessary on the slopes of interior ditches where rock has been washed away and on exterior levees where rock has been washed away or subsided.

- Riprap will not be placed directly on emergent vegetation (e.g., tules, *Scirpus* spp.).
- Emergent vegetation will not be uprooted during the placement of riprap, nor will it be displaced by riprap.
- Riprap placement on the exterior side of the levee will commence and be complete within a 6-hour period, from 3 hours prior to low tide to 3 hours following low tide.

### 4.2.4. Dredging Practices

Dredging has the potential to result in adverse environmental effects if it leads to the release of fine-grained sediments or increasing turbidity, or if it remobilizes contaminated materials. The following preliminary environmental commitments
will be implemented as part of the proposed dredging program to avoid and/or minimize effects on aquatic resources in Suisun Marsh.

- All construction facilities and working platforms required for dredging operations will maintain an operating environment free of fuel spills.
- Runoff generated on the job site will be controlled.
- Dredging activities will occur only between August 1 and November 30.
- Removal of emergent vegetation will be avoided where feasible, although areas of vegetation may need to be disturbed during construction to provide site access, adequate volume of material for construction, and proper water flow at the site. Any unavoidable loss of emergent tidal vegetation from dredging activities in bays, major sloughs, minor sloughs, and dredger cuts will be compensated for by implementing tidal wetland restoration at a 3:1 ratio or 2:1 if restoration is done in advance of the loss.
- Dredging will be avoided within 200 feet of storm drain outfall and urban discharge locations, unless suitable preconstruction contaminant testing is conducted (coordination and consulting with the Dredged Material Management Office (DMMO) relative to evaluation and placement of the materials).
- A berm will be constructed on the channel side of the levee crown to prevent runoff into adjacent aquatic habitats.
- Releases of discharge water from managed wetlands will be limited following dredged material placement.
- The extent of dredging disturbance will be limited based on slough channel habitat classification and plan region as identified in Tables 4 and 5.
- Alternate boating routes will be identified if dredging impedes navigation.

4.2.5. Biological Resources
Best Management Practices

Below are environmental commitments for special-status plants, birds, and fish. Any suspected take of listed species will be reported immediately to DFG and the SRCD, who will immediately contact USFWS or NMFS. Any carcasses of listed fish will be frozen in a whirl-pak bag and retained until instructions are received from the applicable agency.

Biological Monitoring

The project proponents will monitor implementation of environmental commitments pertaining to dredging, riprap placement, or work on the water side of exterior levees that removes vegetation and will provide a biologist/environmental monitor who will be responsible for monitoring implementation of the conditions of any state and federal permits (CWA Sections 401, 402, and
Plants

An on-site field inspection for special-status plants will be conducted by a USFWS-approved biologist for managed wetlands activities on the water side of exterior levees. This includes all water control structure replacement and riprap placement, except when a headwall is present; installation of exterior water control structures; alternative bank protection placement; and dredging and other facility maintenance activities that remove vegetation. Special-status plants include:

- soft bird’s beak (*Cordylanthus mollis* ssp. *mollis*)
- salt marsh bird’s beak (*C. maritimus* ssp. *maritimus*)
- hispid bird’s beak (*C. mollis* ssp. *hispidus*)
- Delta tule pea (*Lathyrus jepsonii* var. *jepsonii*)
- Mason’s lilaeposis (*Lilaeopsis masonii*)
- Suisun thistle (*Cirsium hydrophilum* var. *hyrdophilum*)
- Suisun Marsh aster (*Aster lentus*)
- alkali milk-vetch (*Astragalus tener*)
- heartscale (*Atriplex cordulata*)
- brittlescale (*Atriplex depressa*)
- valley spearscale (*Atriplex joaquiniana*)

If a special-status plant is found during a survey, it will be avoided, and a map showing the location of the plant will be provided to DFG, the Corps, and USFWS no later than 7 calendar days after the survey is completed. If a special-status plant cannot be avoided during the proposed work and it is not listed as threatened or endangered, the plant will be carefully transplanted to the nearest suitable habitat provided this action and the proposed transplantation site are determined by DFG to be adequate to offset any impact. If approved by DFG, a qualified representative of SRCD or DFG may conduct the transplantation. If DFG does not determine that transplantation will offset the impact, a restoration plan will be prepared and implemented, after DFG approval, that will be able to ensure that impacts on the plant population are offset. This determination by DFG will include an assessment of species distribution, the abundance in the Marsh, and the level of proposed impact.

If a federally listed threatened or endangered plant is found that cannot be avoided during the proposed work, the qualified representative of SRCD or DFG will notify the Corps immediately so it can consult with the USFWS. If determined necessary by USFWS and if a federally listed plant cannot be avoided during the proposed work, the plant will be carefully transplanted to the nearest
suitable habitat provided this action and the proposed transplantation site are determined by USFWS to be adequate to offset any impact. If approved by USFWS, a qualified representative of SRCD or DFG may conduct the transplantation. If USFWS does not determine that transplantation will offset the impact, a restoration plan will be prepared and implemented, after USFWS approval, that will be able to ensure that impacts on the plant population are offset. This determination by USFWS will include an assessment of species distribution, abundance in the Marsh, and the level of proposed impact.

Birds

- Limit work in California clapper rail habitat between February 1 and August 31 unless surveys indicate that California clapper rail is not present. Figure 3 depicts the areas of habitat to be avoided during this time.
- Impacts on great blue heron and egret rookeries will be avoided and minimized by removing mature trees only outside the nesting season and maintaining a 500-foot buffer between roost sites and managed wetland activities during the nesting season.
- Managed wetland activities in the vicinity of active raptor nests will not be implemented during breeding season.

Fish

- To minimize entrainment losses of fish throughout the Marsh, water control structures will be consolidated and/or equipped with state-of-the-art fish screens when practicable and as funding allows. Intakes that present the highest risk of entrainment to salmonid smolts will be given the highest priority, including intakes located on Montezuma, Suisun, and Cordelia Sloughs.
- Any new or enlarged exterior water intakes and/or control structures will be screened in accordance with DFG’s criteria unless DFG and the Corps determine that the structure would not adversely affect any listed species and the Corps obtains concurrence for any federally listed species with that determination from NMFS and/or USFWS as applicable.
- Water control structures will be installed or replaced only during low tides (within a 6-hour period, from 3 hours prior to low tide to 3 hours following low tide) when there is the least chance of affecting fish.
- SRCD and DFG will continue to identify and prioritize placement of water control structures that require fish screens in consultation with the Corps, NMFS, and the USFWS. The SRCD and DFG will seek funding to install screens at the highest-priority sites.
- Water control structures will be operated to minimize impacts on listed fish, taking into consideration seasonal timing and water quality (e.g., structures may be installed or replaced during low tides (within a 6-hour period, from 3
hours prior to low tide to 3 hours following low tide) when there is the least chance of affecting fish).

- All in-water work will be done by hand and during low tide (within a 6-hour period, from 3 hours prior to low tide to 3 hours following low tide) as part of the following activities: repair, replacement, or installation of exterior water control structures; pipe replacement at the exterior flood or dual-purpose gate; pipe replacement at the existing exterior drain gate; and installation of the new exterior drain structure.

- All levee repairs and pipe replacements will be restricted to the dry season and not done in the rain.

- Repairs of existing exterior levees, to stop the flow of tidal waters entering into the managed wetlands, will be completed within 7 days of the breach for coverage under the RGP/SMP.

- Fish screens will be installed on any new or enlarged water control structures.

- No more than 1,000 square feet of wetlands per year throughout the Marsh will be filled during installation of fish screens.

- A biologist or on-site monitor will evaluate each site during project implementation of exterior pipe replacement or riprap placement on exterior levees to document project actions for the purpose of identifying any condition that could adversely affect salmonids, green sturgeon, or their habitat. Whenever conditions are identified that could adversely affect salmonids, green sturgeon, or their habitat in a manner not described in the opinion, Reclamation, USFWS, the Corps, its permittee, or the contractor will notify a NMFS biologist immediately.

- If Reclamation, USFWS, the Corps, its permittee, or the contractor identifies a project-related condition that could adversely affect salmonids, green sturgeon, or their habitat in a manner not anticipated, the Corps, its permittee, or the contractor will be responsible for rectifying such changes in a timely manner.

- If the managed wetlands are subject to uncontrolled tidal flow, dewatering of the managed wetland area will be conducted through the use of existing gravity tidal drainage gates as much as possible. DFG will be consulted to determine whether fish salvage efforts are needed prior to completely dewatering the site.

### Water Diversion Restrictions

- SRCD will notify DFG, NMFS, and the Corps of the starting and closing dates of duck hunting season annually at least 1 month prior to the start of the season. Landowners diverting water from sloughs designated by NMFS (Montezuma Slough and its tributaries, lower Nurse Slough [from the confluence with Denverton Slough to Montezuma], Denverton Slough; Cuttoff Slough [including Spring Branch Slough, first and second Mallard Branch Slough]; Suisun Slough, [from downstream of the confluence with Boynton Slough to Grizzly Bay; and Chipps Island]) will use no more than
25% of the water control structure’s diversion capacity from November 1 to the last day of duck hunting season. These landowners are prohibited from diverting water from designated sloughs from February 21 to March 31. The purpose of these diversion restrictions is to protect migrating salmonids. Table 7 describes the diversion restrictions.

Table 7. Inches of Water Discharged through Pipe for Salmonid Restriction

<table>
<thead>
<tr>

Landowners diverting water from sloughs designated by NMFS (i.e., Montezuma Slough and its tributaries, lower Nurse Slough [from the confluence with Denverton Slough to Montezuma], Denverton Slough; Cuttoff Slough [including Spring Branch Slough, first and second Mallard Branch Slough]; Suisun Slough, [from downstream of the confluence with Boynton Slough to Grizzly Bay; and Chipps Island]) will use only 35% of the water control structure’s intake capacity between April 1 and May 31. If, during this time, two out of the three DFG 20-millimeter trawl surveys sites (sites 606, 609, and 610) predict delta smelt densities greater than 20 delta smelt individuals per 10,000 cubic meters over a 2-week sampling period, all diversions from these sloughs will use only 20% of the water control structure’s intake capacity. Survey trawls will take place at least once every 14 days between April 1 and May 31. Table 8 below determines delta smelt diversion restrictions.

Table 8. Inches of Water Discharging through Pipe for Delta Smelt Restriction

</tbody>
</table>
While diversion restrictions are in place, SRCD and DFG will monitor gate closures. If an open gate is observed, they will immediately contact the landowner, and the gates will be brought into compliance (i.e., closed).

4.2.6. Construction Period Restrictions

Timing of construction activities will depend on the type of activity, presence or absence of sensitive resources, tides, and/or water management in wetlands. In general, in-water work associated with exterior levee activities will occur between August 1 and November 30, which avoids most of the special-status fish species. Additionally, most of the managed wetland activities are expected to be implemented from June to September when the wetlands are dry enough to conduct these activities (Figure 4). Activities may be conducted during other times of the year, depending on the potentially affected species for each site-specific case. Activities occurring during the hunting season will not occur on Saturday, Sunday, or Wednesday when such activities have a reasonable possibility of disrupting access to hunting or represent a safety concern. Furthermore, construction will not occur during major summer holiday periods, and adequate warnings signs, postings, and/or notices will be provided upstream and downstream of all construction equipment, sites, and activities to warn recreational boaters. Finally, signs describing alternate boating routes will be posted when construction activities limit and/or restrict boating access.

4.2.7. Hazardous Materials Management Plan

A hazardous materials spill plan will be developed for the managed wetland activities. The plan will describe the actions that will be taken in the event of a spill. The plan also will incorporate preventive measures to be implemented (such as vehicle and equipment staging, cleaning, maintenance, and refueling) and contaminant (including fuel) management and storage. In the event of a contaminant spill, work at the site immediately will cease until the contractor has contained and mitigated the spill. The contractor immediately will prevent further contamination, notify appropriate authorities, and mitigate damage as appropriate. Adequate spill containment materials, such as oil diapers and hydrocarbon cleanup kits, will be available on site at all times.

4.2.8. Cultural Resources

- If any previously unknown historic or archeological artifacts are discovered while accomplishing the authorized work, the landowner must stop work immediately and notify the Corps. The activity is not authorized until the requirements of Section 106 of the NHPA have been satisfied.
- Work is not authorized within 100 feet of archeological site CAL-SOL-13.
5. **Plan Implementation Strategy**

The SMP is predicated on the assumption that each Principal Agency will implement or approve activities in the Marsh consistent with the SMP and its own mission and jurisdictional authority. The primary components of the strategy are to:

- Implement the environmental commitments and mitigation measures in the SMP EIS/EIR and other required state and federal permit measures to ensure that resources are protected and that restoration and managed wetland goals are met simultaneously.
- Implement adaptive management to ensure impacts described in the SMP EIS/EIR are not exceeded and to improve the ecological effectiveness of restoration over the period of implementation of the SMP.
- Prepare annual reports on the status of SMP restoration and managed wetland activities.

5.1. **Meeting Restoration and Managed Wetland Goals Simultaneously**

The SMP will contribute to recovery of many species in the Marsh. Based on the analysis in the SMP EIS/EIR, implementation of the SMP restoration and managed wetland activities and environmental commitments will provide sufficient tidal restoration and resource protection of fish and wildlife resources to both offset potential impacts on those resources and contribute to recovery of listed species. As such, both restoration and managed wetland activities will proceed simultaneously, and implementation will be planned to carefully monitor and mitigate the effects of SMP activities.

The managed wetland activities will be implemented only if at least one third of the total restoration activities will be implemented in each of the 10-year increments. Therefore, it is expected that, for example, 1,600–2,300 acres in the Marsh will be restored by year 10, an additional 1,600–2,300 acres will be restored by year 20, and the full 5,000–7,000 acres will be restored by year 30. This will ensure that all actions will be implemented in a timeframe similar to that of the impacts and that restoration efforts will contribute toward recovery throughout the plan implementation period. If these 10-year incremental SMP restoration goals are met, both the managed wetland activities and tidal restoration will continue to ensure that the SMP goals will be met. Options for addressing conditions in which these incremental goals are not met are described below. Under this strategy, the restoration and managed wetland goals will be achieved concurrently. How the restoration acres will be applied for purposes of other regulatory permitting requirements (i.e., recovery vs. mitigation) will be specified through each permit as applicable.
5.2. Project-Specific Implementation

The SMP likely will rely on several restoration actions to meet the restoration goals. Some sites have been identified as available for restoration (e.g., Hill Slough), and other properties that have the characteristics desired for restoration are anticipated to become available for purchase (see Table 1). The SMP attempts to describe a typical restoration action in an effort to fully describe the potential impacts of the restoration element of the SMP because the SMP EIS/EIR is intended to provide as much environmental analysis as possible with the limited site-specific information relative to the 30-year plan implementation. In some site-specific instances, the project proponent will be able to rely solely on the SMP EIS/EIR for the California Environmental Quality Act (CEQA) and/or National Environmental Policy Act (NEPA) compliance, and under other circumstances, the SMP EIS/EIR may be tiered from or supplemented to disclose all potential environmental impacts. The approach for each restoration action will be determined by the specific lead agencies and will be based on the SMP EIS/EIR, project-specific design components, consideration of any new information (including that obtained through implementation of the Adaptive Management Plan [AMP]), or other factors.

The managed wetland activities will be implemented by the SMPA Agencies, including SRCD, which represents private landowners and reclamation districts in the Marsh, as described for each activity, and this EIS/EIR discloses all resulting potential impacts. As such, additional CEQA and/or NEPA documentation is not expected to be required over the 30-year plan implementation period for the management activities.

5.3. Adaptive Management

Adaptive management is essential to keeping the SMP on track toward its objectives, while avoiding and minimizing potential impacts associated with the implementation of SMP actions. The adaptive management process will use data from monitoring the effectiveness of implemented actions, research addressing uncertainties associated with the plan, and other information to inform changes to plan implementation. The adaptive management process will permit changes to be made that will assist in the design of future steps. It also will assist project proponents in understanding the restored system and will aid their ability to explain management actions to Marsh neighbors and the general public. Figure 5 depicts a diagram of the adaptive management process.

Restoration practitioners have found that, because knowledge of natural and social systems is incomplete, systems will respond in unexpected ways. Surprises are also inherent in restoration because nature is variable and unpredictable, especially at large spatial scales and over long timeframes. Adaptive management allows project proponents, Suisun Adaptive Management Advisory Team (AMAT) or the Charter Principals Group to prepare for and respond to events, ranging from unexpected changes in habitat to vandalism. When and where such events occur may not be predictable, but part of the
The adaptive approach is to anticipate the range of events and system responses that might occur and develop a process for dealing with them when they happen. Monitoring and adaptive management can help prevent unintended consequences of implementing actions under the SMP or, when they occur, can avoid unnecessary recurrence, help to minimize any negative impacts, and address issues before they become substantial.

The AMP (Appendix A) was prepared in accordance with the Department of Interior Adaptive Management Technical Guide (Williams et al. 2009) and uses the concepts of passive and active adaptive management. Through passive adaptive management, the Suisun Marsh Charter Principals Group will learn how to ensure better attainment of the SMP’s objectives based on the measured success of previous actions (as indicated by effectiveness monitoring results). The SMP also will take an active adaptive management approach by encouraging project proponents to identify uncertainties applicable to their specific projects and carry out targeted studies to resolve uncertainties related to the best approaches for achieving project-specific objectives. Project proponents could design and implement experimental pilot projects to test the relative efficacy of several approaches for attaining an objective and evaluate different monitoring techniques.

The Sacramento–San Joaquin Delta Reform Act of 2009 (Act) created the Delta Stewardship Council (DSC), disbanded the CBDA, and transferred CBDA’s CALFED responsibilities to the DSC. Therefore, the coordination that occurred among the Principal Agencies and CBDA staff during preparation of the SMP will be transferred to coordination with DSC staff. As the DSC generally is recognized as a clearinghouse of scientific information related to Delta planning efforts in support of the goal of improving water supply reliability and ecosystem functions, tidal restoration planning efforts during implementation of the SMP will include coordination with DSC staff.

While tidal restoration project planning and design rely ultimately on the project proponents for each project, the AMAT will provide a network of technical staff from the Principal Agencies and other agencies involved in Suisun Marsh planning issues, including the DSC, as appropriate. The SMP’s adaptive management approach will involve stakeholders, including the DSC, and include periodic independent science review of SMP implementation by the Delta Science Program. An MOU among the AMAT agencies will be pursued defining the roles and responsibilities of the members with respect to achieving the SMP objectives and implementing adaptive management. The AMAT will make recommendations to the Suisun Principal Agencies as appropriate.

The SMP will occur over a 30-year implementation horizon. The SMP’s adaptive management approach will allow project proponents, AMAT, or the Charter Principals Group to learn from their actions and will:

- Generate science-based information for project proponents.
- Convert information into effective management decisions.
Figure 5
Adaptive Management Process
- Involve stakeholders, including the DSC, to help provide management direction.
- Store and organize information for use by current and future decision-makers and stakeholders.
- Include periodic independence science review of plan implementation and advice using the Delta Science Program.

5.3.1. Adaptive Management Approach

Project implementation will be guided by the best available information but will be monitored and implemented with the goal of increasing understanding about the science of restoration. The opportunities for restoration and research are unknown because of the inability to predict where restoration projects will occur. As described above, the SMP is consistent with the Recovery Plan in splitting restorable acreage into specific regions in order to provide a range of environmental gradients necessary to contribute to the recovery of multiple listed species. Implementation of the SMP Mitigation Monitoring and Reporting Program (Appendix B) will inform adaptive management decision-making and tidal restoration planning efforts.

This adaptive management approach is designed to assist in achieving the SMP objectives by providing a guided approach to learning from restoration, research, monitoring and management actions, and actions that have uncertainties. Results of effectiveness monitoring may indicate that some restoration and management measures are less effective than anticipated. To address these uncertainties, the monitoring and adaptive management program will:

- Ensure impacts on benthic communities from dredging activities described and analyzed in the SMP EIS/EIR are not exceeded.
- Gage the effectiveness of restoration projects and techniques to implement SMP objectives.
- Track project-specific targets to ensure restoration benefits listed species.
- Propose alternative or modified measures as the need arises consistent with available funding.
- Be used to improve future restoration designs to achieve desired physical and ecological results.

As such, potential monitoring associated with adaptive management falls into two categories. The first category is monitoring required to ensure impacts analyzed in the EIS/EIR are not exceeded. This will be accomplished by benthic community recovery monitoring during implementation of the dredging program as described in Chapter 2 of the SMP EIS/EIR. Benthic monitoring will be implemented by the SRCD and DFG in accordance with the requirements of the USFWS and NMFS BOs on the effects of the SMP.
The other potential category of monitoring that will occur under the SMP will be based on key uncertainties and will be considered for implementation as applicable for each tidal restoration project to assess project outcomes. Currently, monitoring in the Suisun Marsh is being carried out by a number of agencies and organizations (see Section 5.4, Monitoring). This monitoring will provide additional information toward the key uncertainties.

5.3.2. Conceptual Models and Uncertainties

During preparation of the SMP, conceptual models were developed for several resource categories, including wetlands, tidal marsh and aquatic habitat, levees, scalar transport and geometry, and water quality. These conceptual models have been developed to assist projects with information regarding the current scientific understanding of the Marsh and identify uncertainties and potential actions. The models can be used to assist with selecting, designing, and predicting outcomes of project-specific design and objectives. These conceptual models include Organic Matter, Mercury, Levee, Tidal and Aquatic, and Managed Wetlands and are accessible at:

Despite the extensive scientific information available, the SMP conceptual models identified a number of scientific uncertainties and knowledge data gaps that still exist. However, not all the uncertainties can be resolved before restoration starts. In fact, many data gaps can be addressed only by implementing restoration actions and learning from the results. Therefore, these uncertainties form the basis for potential monitoring that could apply to specific restoration projects. Each restoration project will be unique and have distinct questions appropriate for monitoring or additional scientific studies. All new information gathered will be combined with existing monitoring data for the Marsh and collected to formalize knowledge, develop expectations of future conditions and outcomes that can be tested by further monitoring, and assess the likelihood of outcomes. Conceptual models are templates for organizing information and will require revision and updating based on monitoring results and new scientific knowledge.

In addition to the resource-specific uncertainties identified in the conceptual models, climate change and changes to Delta outflow are two overarching long-term uncertainties that have been identified and may affect the Marsh. The effects of rising sea levels on tidal marshes are dependent on the relative rate of sea level rise versus rates of sedimentation and accretion of the marsh surface. Sea level rise will cause salinity levels to increase up the estuary as tides push higher up bays, rivers, and sloughs. The Suisun Bay and the Delta may become saltier. Closer study is needed of the potential amount and extent of salinity and habitat change, and the species-level effects of these changes. The maintenance of tidal marsh habitat area during sea level rise requires (1) space for tidal marshes to expand upward into adjacent habitats as sea and tide levels increase; (2) available sediment adequate to support marsh accretion rates equal to or
greater than the rate of sea level rise; (3) stable erosion rates, or at least rates that
do not defeat marsh accretion. The first of these requirements—room for
marshes to “move up” in elevation—is especially problematic in many areas of
the San Francisco Bay estuary where tidal marsh abuts a dike, levee, seawall, or
other human barrier at its landward edge. The requirement for moderate erosion
rates is also of concern, given that climate change and sea level rise in California
are expected to be accompanied by increased storm severity and maximum wave
heights. Sediment supply for marsh accretion is not yet well understood.

The SWP and CVP operations affect Suisun Marsh salinities by regulating Delta
outflow through upstream reservoir storage and releases and Delta exports.
Several other plans and policies are being developed that have the potential to
affect the Marsh. These plans are in varying stages of development, and details
on how they would affect the Marsh are limited at this time. As information is
made available for these uncertainties, it will be incorporated into tidal
restoration planning efforts as appropriate in the future.

5.3.3. Plan Response to Predicted Sea Level Rise

The SMP EIS/EIR evaluated the long-term alternatives for the SMP over a
30-year planning horizon, including consideration of global climate change and
relative sea level rise on habitat distributions, ability to support target ecological
functions, and flood hazards. Relative sea level rise—or the rate of sea level rise
expected to be observed locally—is a product of global sea level rise, tectonic
land movements, and local subsidence and sedimentation. The rate of global sea
level rise is expected to continue along a global warming–induced trajectory, and
model-based predictions of sea level rise range from low estimates of 0.18 to
0.38 meter and high estimates of 0.26 to 0.59 meter by the end of the twenty-first
century (Intergovernmental Panel on Climate Change 2007). A regional study
estimates that the sea level will increase in California between 12 and 17 inches
(0.3 and 0.4 meter) by 2050 and between 20 and 55 inches (0.5 and 1.4 meters)
by 2099 (San Francisco Bay Conservation and Development Commission 2009).
More recent Ocean Protection Council (OPC) estimates are consistent with these
estimates (Vermeer and Rahmstorf 2009). Although significant uncertainty
exists regarding these rates, ongoing research regarding the primary factors
affecting global and regional sea level rise continues to narrow the uncertainties
and refine future estimates.

Looking forward, if sea level rise matches the mid-range of the
Intergovernmental Panel on Climate Change (IPCC) (2007) predictions and
sediment availability to the Marsh remains the same, sustainable vegetated tidal
marshes are expected to develop in the tidally restored ponds within the plan’s
30-year planning horizon. If higher rates of sea level rise prevail, tidally restored
areas within the SMP area may persist as intertidal unvegetated mudflats or
shallow open-water habitat for prolonged periods. Many tidally restored
wetlands still would be expected to accrete sediment and eventually support
vegetated tidal marsh, except at a slower rate, although some restorations in
Suisun could remain unvegetated well into the foreseeable future.
Higher than anticipated sea level–rise rates that result in delayed or arrested marsh establishment could hinder the progression toward tidal wetlands, resulting in a mix of habitats, including managed wetlands, tidal wetlands, open-water, and subtidal aquatic habitats. Sea level rise represents only one of many uncertainties that could affect the ultimate habitat mix.

A number of features can be built into the restoration efforts to support achieving long-term ecological functions. Providing for the tidal wetland to advance “upslope” can be achieved through constructing a gradually sloping wetland/upland transition zone at interior sites and selecting restoration sites at the wetland-upland edge of Suisun that provide an elevation gradient over which tidal wetland could shift upslope as sea level rises. Promoting early emergent vegetation can help to capture sediment for marsh accretion, and it can enhance the accumulation of organic matter in the developing wetland sediments. This could be accomplished by managing lands prior to restoring tidal action to promote wetland plant biomass accumulation that reverses subsidence.

The potential for sea level rise is acknowledged in the site selection considerations and therefore will be a recurring consideration based on best available science for each restoration project. Administration of this criterion will recognize the dynamic nature of the land/water interactions, including subsidence, sediment accretion potential, and biomass accumulation potential. This will enable project designs to be based on habitat trajectory (as opposed to current or static conditions) over the 30-year planning horizon. This approach will help minimize “sunk cost” of habitat and facility investments as well as help ensure that the targeted habitat type occurs as planned. In addition to site selection and project design considerations, the AMP provides a framework for adapting to sea level rise.

Wetland operations and levee maintenance will be adjusted over time with sea level rise. Flood protection levees will be designed to accommodate future sea level rise, either with higher crown elevations at the time of initial construction or with the flexibility to add levee height in the future. Ongoing levee maintenance will maintain levee crown elevations as needed to provide continued flood protection with sea level rise. In general, raising levee crown heights requires widening the levee footprint in order to maintain levee stability. Wetlands also will be more difficult to drain by gravity at low tide, thereby reducing water management ability, which can be offset mainly through increased use of pumps for managed wetland drainage, with some clubs continuing to be gravity-drained but with greater management options to take best advantage of every low tide.

5.4. Monitoring

5.4.1. Ongoing Monitoring

Monitoring is ongoing in the Marsh to varying degrees on public and private lands and public waters. For example, the Interagency Ecological Program is composed of state and federal agencies, as well as university and private
scientists, who conduct long-term monitoring and applied research in the San Francisco estuary directed toward effective management. Several ongoing monitoring programs exist in the Marsh.

- **Salt Marsh Harvest Mouse Surveys:** These surveys are conducted annually by DFG and DWR to monitor SMHM populations.

- **California Clapper Rail and Black Rail Surveys:** These surveys are conducted annually by DFG to monitor clapper rail and black rail breeding pairs.

- **Suisun Marsh Vegetation Surveys:** These surveys are conducted every 3 years by DFG to monitor vegetation changes throughout the Marsh. An aerial survey is flown every 3 years and using GIS, produces a precise vegetation map with detailed descriptions of vegetation types. This survey is used to support monitoring of SMHM and California clapper rail habitat, and can be used by private landowners to evaluate managed wetlands habitat response to management activities. Recently, this monitoring has included breach and channel network evolution for the Blacklock Tidal Restoration Project.

- **Water Quality Monitoring:** DWR maintains water quality and tide stage monitoring stations throughout the Marsh as part of the California Data Exchange Center (CDEC) monitoring network. These stations measure a variety of parameters, depending on the station, that may include precipitation, water temperature, wind speed and direction, and atmospheric pressure on an hourly basis. Data are telemetered to CDEC so tide stage can be monitored remotely.

- **Interagency Ecological Program Database:** This database contains data collected by UC Davis, DFG, and the USFWS, including fishery, benthos, nutrient, pesticide, bioassay, water-weather condition, and survey fish tag data (<http://www.water.ca.gov/iep>).

- **Blacklock Restoration Project:** This tidal restoration project has a monitoring plan that includes levee breach geometry, inundation regime monitoring, marsh surface-elevation changes/sedimentation accretion, slough network evolution, native marsh vegetation, wildlife, water quality, methyl mercury, and erosion of adjacent sloughs.

- **SRCD, DFG and Private Lands Reporting:** Annually, SRCD compiles a summary report of actual annual managed wetlands maintenance work completed under the Corps RGP3. In compliance with this permit, DFG and SRCD also conduct compliance inspections for diversion restrictions and submit report to the regulatory agencies.

- **DFG Grizzly Island Wildlife Area:** DFG conducts annual surveys for wintering waterfowl and breeding surveys for tule elk, pheasant, and waterfowl.

- **Audubon Society Christmas Bird Count:** These data are collected annually to study long-term health and status of bird populations across North America. Surveys are conducted in the Marsh every year as the
Benicia (CABE) count circle (<http://birds.audubon.org/christmas-bird-count>).

- **Tricolored Blackbird Surveys**: These surveys are carried out every 3 years during April. DFG participates in this statewide survey coordinated by Audubon California (<http://tricolor.ice.ucdavis.edu/>).

- **Solano County Mosquito Breeding Habitat Monitoring**: Adult mosquitoes are routinely monitored (7-night cycles) throughout the Solano County Mosquito Abatement District. Each week (from April through October) the samples are identified after which the findings are sent to the California Department of Health Services Vector Borne Disease Section (<http://www.solanomosquito.com/aboutus.html>).

Several other monitoring programs are being implemented that could provide useful information in the SMP adaptive management decision making process.

- **South Bay Salt Ponds Project**: USFWS is monitoring similar restoration targets and objectives.

- **Dutch Slough Restoration Project**: DWR is monitoring fish hypotheses, water quality hypotheses, and miscellaneous bio-geomorphic hypotheses.

- **Napa River Salt Marsh Restoration Project**: DFG is monitoring wildlife use of evolving tidal habitats.

- **Bay Delta and Tributaries (BDAT)**: BDAT contains environmental data concerning the San Francisco Bay-Delta and provides public access to those data. More than 50 organizations contribute data voluntarily to this project. The database includes biological, water quality, and meteorological data. These can be used to gage the health of the estuary and to manage water.

- **UC Davis Fish and Invertebrate Study**: This monthly study uses multiple methods to sample fish in shallow, brackish-water habitat and has been designed since inception to monitor the status of fishes in the Marsh.

- **Time-Series Databases**: Hydrodynamics and water quality data of the California Bay-Delta Tributary collected by various agencies at more than 120 stations (mostly fixed-position stations) using the data storage system, which is suitable for time-series data and was developed by the Hydrologic Engineering Center of the Corps.

- **California Waterfowl Association**: Waterfowl nesting surveys are conducted on the Grizzly Island Wildlife Area to help monitor and assess waterfowl populations.

Information from these monitoring efforts is currently reported to the Suisun Environmental Compliance Advisory Team for use in agency planning efforts.
5.4.2. Environmental Impact Statement/Environmental Impact Report Monitoring

As previously mentioned, because there is scientific uncertainty regarding recovery times for benthic communities, SRCD and DFG will initiate a benthic community monitoring program concurrent with the implementation of the new dredging program in accordance with the USFWS and NMFS BOs. The objectives of this monitoring are to determine benthic community richness and abundance prior to and following dredging at selected sites, with an extended post-dredging component to determine species reestablishment of disturbed areas over an appropriate period of time. The purpose of this effort is to confirm the potential impacts of dredging on benthic invertebrate communities in the vicinity of dredging activities and to make necessary adjustments to the dredging program to ensure that the anticipated effects as analyzed in the SMP EIS/EIR and BOs are not exceeded.

5.4.3. Potential Tidal Restoration Project Monitoring

Under the SMP each tidal restoration project will have its own specific objectives in support of the overall SMP tidal restoration objective of implementing 5,000 to 7,000 acres of tidal marsh restoration in the Marsh and contributing to recovery of listed species consistent with the Recovery Plan. Therefore, as applicable to project-specific objectives, project-specific monitoring will be recommended based on the previously described uncertainties during project planning and design. Project proponents will be responsible for implementing monitoring as incorporated into project planning documents. The approach for each restoration action will be determined by the specific lead agencies and will be based on the SMP EIS/EIR, project-specific design components, consideration of any new information (including that obtained through the SMP adaptive management), or other factors. Each project will create a monitoring plan that clearly identifies each monitoring activity, expected results, and responsible party for each monitoring activity.

During project monitoring planning, project proponents will (1) assemble all available data; (2) determine priorities; (3) identify focal species or suites of species, if appropriate; (4) identify performance indicators; and (5) develop monitoring protocols if none exist.

To make monitoring useful, choices of ecological attributes to monitor and how to monitor them (e.g., frequency, extent, intensity) must be linked closely to the management situation that motivates the monitoring in the first place. There are always limits on staff and funding for monitoring, and it is important to choose design protocols that will provide the most useful information within those limits. Protocol design should be based on the purposes of monitoring and the way in which monitoring data will be analyzed.
When possible, monitoring methods will be designed to collect data from multiple parameters. For example, aerial photographs or satellite images can show the extent of tidal marsh, connectivity of habitats, form and location of channels, and changes in invasive plant populations. After choosing parameters and methods, monitoring protocols must be used and, if not in existence, must be developed. These protocols must be designed to collect enough data at a scale and frequency that allow project proponents to discern spatial differences and trends through time. Monitoring will be targeted at specific mechanisms thought to underlie measures and or actions and be used to assess results. Monitoring actions will be prioritized, and considerations should include feasibility of implementation, availability of funding, and uncertainty of outcome. Capturing baseline condition information, if it is not already available, will be a component of any project-specific monitoring plan.

There are several types of monitoring that will be implemented as part of tidal restoration projects under the SMP.

- Compliance monitoring will be built into project-specific permit requirements.
- Performance monitoring will identify whether project-specific actions are achieving their expected outcomes or targets.
- Mechanistic monitoring will demonstrate whether the mechanisms thought to link actions to desired outcomes are working as predicted.

Project monitoring needs to be designed to help reduce uncertainty, be measurable with observable responses to project implementation, noting that subtle differences in responses before and after project implementation seldom are detected. Tidal restoration project proponents will receive input from the AMAT (further described in Section 5.4.1 below) and Suisun Principals regarding project planning, design, and monitoring. In addition, it is recommended that each individual tidal restoration project seek the input of other science-based work groups to develop goals, objectives, and performance measures for each restoration project, as applicable.

The following sections summarize categories for which key uncertainties have been identified (as listed in the previous section) and potential monitoring that could be recommended, as applicable, for specific tidal restoration projects.

**Managed Wetland Enhancement**

There is scientific uncertainty regarding the potential effects of tidal restoration on species currently using managed wetlands. As the SMP’s purpose is to create an acceptable balance between protection and enhancement of managed wetlands and the species that use them, and the restoration and protection of tidal wetlands, monitoring in this category will be crucial to balanced implementation of the SMP. Monitoring in this category will be closely integrated with existing monitoring efforts in the Marsh.
Objectives of this monitoring will include gaining information related to one or more of the following key uncertainties.

- Managed wetland enhancement effects on resident and migratory wildlife species and plant populations.
- Regional waterfowl habitat availability and quality and the effects of managed wetland enhancement actions on indicators of waterfowl use.

**Tidal Restoration**

The expected outcome of tidal restoration is the creation of marsh habitat for endangered soft bird’s-beak (*Cordylanthus mollis* ssp. *mollis*), endangered Suisun thistle (*Cirsium hydrophilum* var. *hydrophilum*), endangered California clapper rail (*Rallus longirostris obsoletus*), and endangered SMHM (*Reithrodontomys raviventris*) which will contribute to the recovery goals in the USFWS’s Suisun Bay Area Recovery Unit. There is uncertainty associated with the ways tidal restoration may change natural processes during SMP implementation. Tidal marsh development will vary depending on its location within the Marsh.

Evaluating primary productivity at a tidal restoration site attempts to determine whether a restoration project supports native fish species, including Chinook salmon, delta and longfin smelt, and other pelagic organisms by increasing the production of nutritionally valuable phytoplankton and zooplankton. An understanding of the magnitude of fish food production and release from restored tidal marshes in the Marsh is critical to determining the ability of restored intertidal marshes to aid in the recovery of pelagic species.

Objectives of this monitoring will include gaining information related to one or more of the following key uncertainties.

- Use of newly restored tidal habitats by special status plant and wildlife species.
- Tidal restoration effects on resident and migratory wildlife species and plant populations.
- Regional waterfowl habitat availability and quality and the effects of tidal restoration actions on indicators of waterfowl use.
- Producer population growth in newly restored tidal habitats.
- Nutrient cycling.
- Zooplankton growth and availability in newly restored tidal habitats.
- Native and nonnative fish habitat use and residence time in newly restored tidal habitats.
**Water Quality**

Multiple factors contribute to the degradation of water quality in the Marsh, including increased salinities from tidal restoration projects, some flooding and drainage practices in managed wetlands, minimal tidal exchange in dead-end sloughs, urban runoff, and naturally occurring contaminants such as mercury. Improvement of water quality and water quality management practices will benefit ecological process for all habitats, including managed and tidal wetlands.

In cooperation with regional monitoring and research efforts, sediment and water quality monitoring could be conducted at several tidal restoration project sites. Ongoing information can be used adaptively to correct long-term construction and management plans and activities associated with restoration. Water quality parameters that could be monitored include salinity, temperature, DO, and methylmercury.

Objectives of this monitoring will include gaining information related to one or more of the following key uncertainties.

- Carbon production with tidal restoration and potential for transport to Delta pumps and contribution to trihalomethane production.
- Burial or exposure of existing mercury deposits in the Marsh.
- Marsh biota exposure to mercury and reducing potential for methylmercury exposure and transport in tidal restoration site design.
- Effects of short-term pulses of methylmercury versus long-term annual concentrations.

**Hydrodynamic Modeling**

Hydrodynamic modeling is employed as a planning and predictive tool to investigate alternative breach options for tidal restoration projects. Hydrodynamic modeling at a planned and/or naturally occurring breach could be used as an indicator of outcome and a possible diagnostic tool to evaluate changes in tide stage, inundation regimes, or increased salinities that were not anticipated. Cross-sectional profiles of any additional natural breaches (of significant size) should be conducted where appropriate.

The previous sections describe a few examples of monitoring that could be implemented for tidal restoration projects under the SMP, based on key uncertainties identified in the conceptual models. However, this is not intended to be an all-inclusive list, and it is recognized that specific tidal restoration projects will have individual objectives and there may be monitoring for projects that is not captured here. Additional monitoring elements could include those developed for the Recovery Plan, the Bay Delta Conservation Plan Independent Science Advisors, or the DSC. In addition, uncertainties not identified here could be realized during specific tidal restoration project design, and through information learned from completed tidal restoration project monitoring. Such
information will be used to update the conceptual models and this SMP adaptive management approach.

5.5. Adaptive Management Implementation

5.5.1. Roles and Responsibilities

To implement adaptive management, an effective decision-making structure must be developed to complete the loop between information from monitoring and the use of that information in decision-making. To be effective, it must be flexible and designed to be adjusted in the face of uncertainties as outcomes from management actions and other events become better understood. The following structure has been collaboratively working on Marsh issues for more than 10 years and will continue through the implementation of the SMP. The structure for decision-making is designed to achieve these functions.

- Convert information into effective management decisions.
- Incorporate independent science into plan implementation.
- Provide a forum for project development and collaboration.
- Involve the public/landowners to help provide management direction.
- Store and organize information for use by decision-makers and the public.

Suisun Marsh Charter Group Principals

The Suisun Marsh Charter Group Principal Agencies collaboratively have prepared the SMP. The Principals include agency managers from DFG, DWR, Reclamation, USFWS, and SRCD that have experience with Marsh issues, policies, and permits. The Principal agencies are ultimately responsible for decisions that are implemented regarding the SMP. Projects will be reviewed for consistency with the SMP goals and objectives. Principal agency actions related to the SMP are as follows and are further described in the SMP.

Adaptive Management Advisory Team

While project planning and design rely ultimately on the project managers for each restoration project, a network of staff from state and federal agencies will provide an interface for effective science, management, and outreach partnerships. The AMAT will be composed of technical staff from DFG, DWR, SRCD, Reclamation, USFWS, and the DSC with invitations to other entities to participate as appropriate. SRCD will be the lead of the AMAT and will convene meetings and call upon DWR, DFG, Reclamation, USFWS, and the DSC. Project proponents are encouraged to use the AMAT and their knowledge of the Marsh for project development and support and as a forum to coordinate and cooperate for the benefit of the overall restoration goals. An MOU among the
AMAT agencies will be pursued defining the roles and responsibilities of the members with respect to achieving the SMP objectives and implementing adaptive management. While retaining their existing individual land management authorities, project proponents will coordinate with the AMAT to develop project planning and design documentation, quantify specific restoration objectives and targets, and develop monitoring and research plans and schedules to assess the effectiveness of implemented actions in achieving SMP goals and objectives and addressing uncertainties associated with assumptions used to develop the plan. Coordination with the AMAT does not preclude project proponents from their regulatory due diligence. No regulatory authority has been delegated to the AMAT. Each AMAT participating agency retains its own regulatory authority. The AMAT will make recommendations to the Principals as appropriate.

The AMAT will:

- Provide access to detailed and updated conceptual models that synthesize existing knowledge of the Marsh.
- Provide access to ongoing monitoring.
- Review proponents’ projects, restoration targets, and monitoring plans.
- Evaluate whether each project is contributing toward the overall SMP objectives.
- Make recommendations for project additions or changes.
- Conduct periodic reviews of project results.
- Incorporate a feedback loop that links implementation and monitoring to a decision-making process.
- Conduct periodic independent science review of plan implementation using the Delta Science Program.
- Improve restoration designs to achieve desired SMP results.
- Make recommendations to the Principal Agencies regarding implementation of the SMP.
- Submit, every other year, an implementation status report to DFG, NMFS, USFWS, and other regulatory agencies as required.

Information Management

As funding and staff become available for site-specific projects, and in accordance with permit requirements (BOs), data storage and access, including monitoring and/or GIS data, will be collected and made available to act as a link for planning future projects. The AMAT will be responsible for data storage and access, including monitoring and/or GIS data, and act as a link for all data collected. Data collected by this group also will include other relevant projects from around the Bay such as the San Francisco Bay and Napa Salt Ponds.
Restoration Projects. The AMAT will ensure that monitoring data and reports are made widely available, including to the Principal Agencies.

**Stakeholder Participation**

Local stakeholder involvement is essential to meet the SMP objectives. Stakeholders will provide input to the AMAT to help guide restoration and adaptive management actions. The Stakeholder Group could include local public agencies, including SRCD; landowners; and other interested parties to provide ongoing, local landowner–derived input to the Principals on adaptively managing implementation of the SMP.

### 5.5.2. Project Success Criteria

The U.S. Department of the Interior Adaptive Management Technical Guide defines adaptive management as successful if progress is made toward achieving management goals through a learning-based (adaptive) decision process (Williams et al. 2009). It also indicates that successful adaptive management shows recognizable progress toward achieving objectives in a reasonable time frame, implements learning-based management with stakeholder involvement, and is consistent with all applicable laws and regulations. The SMP project success criteria are based on meeting the targets of restoring 5,000 to 7,000 acres of tidal wetlands habitat and protecting and enhancing 40,000 to 50,000 acres of seasonal wetland habitat.

Restoration of tidal wetlands is consistent with the *Draft Recovery Plan for Tidal Marsh Ecosystems of Northern and Central California*. The goal of the Draft Recovery Plan is the comprehensive restoration and management of tidal marsh ecosystems in five recovery units; Suisun Bay, San Pablo Bay, the Central/South San Francisco Bay, Central Coast, and Morro Bay Recovery Units. Restoring 5,000 to 7,000 acres of tidal wetlands will aid in the recovery of the California clapper rail, SMHM, Suisun thistle, and soft bird’s-beak, with the Suisun Bay Recovery Unit.

Because of the long timeframe for tidal marsh evolution and the difference in wildlife values of various types of tidal habitats, it is difficult to determine the end-point for project success. Projects related to, or tiered from, the SMP should incorporate post-construction monitoring and adaptive management to assess whether natural processes can sustain the long-term evolution of tidal marsh.

As elements and processes of managed wetland are constantly changing, adaptive management should be incorporated annually to track and determine the success of enhancement projects.

For each individual project tiered from the SMP, a clear timeline of monitoring will be developed in a manner to document results that will require a
modification of the project, or identify possible new actions needed for the project to perform as intended.

5.5.3. **Assessment of Monitoring Results**

As monitoring data become available, the AMAT will review them for specific projects to assess how successful the individual tidal restoration projects are being at meeting their specific objectives. Also, the AMAT annually will review available monitoring data to assess progress toward achieving the overall SMP objectives. The AMAT will provide recommendations on additional monitoring needs and changes to restoration design based on review of past projects.

5.5.4. **Feedback Loop and Decision-Making**

Technical learning will occur over a relatively short term, during which objectives, alternatives, and other elements remain unchanged. On the other hand, learning about the decision process itself will occur through periodic revisiting of the SMP adaptive management elements over the longer term. The AMAT will act primarily as a feedback loop for new knowledge assimilated from ongoing actions and individual enhancement and restoration projects. An important role of the AMAT will be ensuring clear communication of the current understanding of existing baseline condition data to project proponents during the planning process. Also, the AMAT will provide a forum to advise project proponents of adverse conditions potentially affecting tidal restoration projects early in the planning process. As appropriate, the AMAT will advise the Principal Agencies of the need for changes to the SMP objectives and/or implementation strategy based on new information from project-specific monitoring.

As described below in Section 5.6, the SMPA agencies (Reclamation, SRCD, DWR, and DFG) will submit implementation status reports no less frequently than every other year to DFG, NMFS, and USFWS, and other regulatory agencies that will describe the implemented restoration activities, monitoring, application of adaptive management, results of adaptive management, and any activities that are being planned.

5.6. **Annual Reporting**

To track the progress of restoration and managed wetland activities, the SMPA agencies (Reclamation, SRCD, DWR, and DFG) will submit implementation status reports annually to DFG, NMFS, and USFWS and other regulatory agencies that will describe the implemented restoration activities, monitoring, application of adaptive management, results of adaptive management, and any activities that are being planned, will be submitted no less frequently than every other year.
The SMPA agencies will report the status of restoration and managed wetlands in each report. Additional information will be included in the SMP Biological Assessments and BOs. In general, reports will include the following information.

- The location, extent, and timing of land acquisition for tidal restoration.
- The location, extent, and timing of restoration planning, protection, enhancement, restoration, or creation of tidal wetlands.
- Status of restoration planning for acquired properties.
- Descriptions of conservation agreements, lands acquired in fee title, interagency memorandums of agreement, or any other agreements entered into for the purposes of protecting, enhancing, or restoring tidal or managed wetlands.
- Descriptions of the previous year’s managed wetland activities, including a description of how actual impacts compare to impacts analyzed in the EIS/EIR (this information can be used to determine whether additional CEQA or NEPA documentation is required for future discretionary actions).
- Descriptions of monitoring results, including any actions that will be implemented as a result of this information.
- A summary of how implemented activities compare to SMP goals in terms of habitat types, managed wetland operations, acreage goals, and species composition.

If any report indicates that restoration or managed wetland targets are not being met or have the potential not to be met, the SMPA agencies along with NMFS and USFWS will convene to determine how to proceed to get plan implementation on track. The mutually agreeable plan of action may include a range of potential solutions, including:

- Changes to the manner in which the SMP is implemented.
- Temporarily or permanently adjusting certain SMP provisions through an amendment or other process.
- Slowing or stopping aspects of the managed wetland activities permit issuance until restoration catches up with impacts.

Monitoring and Adaptive Management Plan

I. Introduction

A. Background

Suisun Marsh (Marsh) is the largest contiguous brackish water marsh remaining on the west coast of North America and is a critical part of the San Francisco Bay/Sacramento-San Joaquin River Delta (Delta) estuary ecosystem. It encompasses more than 10% of California’s remaining natural wetlands and serves as the resting and feeding ground for thousands of birds migrating on the Pacific Flyway. In addition, the Marsh consists of several habitat types that provide essential habitat for more than 221 bird species, 45 animal species, 16 reptilian and amphibian species, and the salmon fishery by providing important tidal rearing areas for juvenile fish.

Managed wetlands are the most common land cover type in the Marsh, accounting for approximately 51,416 acres, or 66.5% of the Marsh. Managed wetlands in the study area provide valuable nesting, foraging, and wintering habitat for waterfowl and shorebirds. Managed wetlands also provide nesting and foraging area for several special status species, such as salt marsh harvest mouse, Suisun shrew, California black rail, California clapper rail, western pond turtle, Suisun song sparrow, and salt marsh common yellowthroat. Managed wetlands also provide habitat for raptors, songbirds, and numerous wildlife species.

Bays and sloughs comprise approximately 25% of the Marsh. Bays and sloughs provide foraging habitat for several species of diving ducks, cormorants, grebes, and other waterfowl that are permanent residents or that winter in the Marsh. The upper reaches of the sloughs provide foraging habitat for waterfowl species, kingfishers, piscivorous birds and wading birds. Shallow freshwater aquatic areas provide rearing, escape cover, and foraging habitat for reptiles and amphibians and may be used as foraging habitat by river otters and raccoon. This habitat also provides the largest area of habitat for fish species in the Marsh. Section 6.1 of the SMP EIS/EIR contains further information on fish habitat in the Marsh.

Tidal wetlands make up approximately 7.5% of the Marsh and are divided into three zones – low marsh, middle marsh, and high marsh. The low tidal zone receives tidal inundation twice a day and provides habitat for shorebirds, California clapper rail, California black rail, other wading birds, and many fish species. Dominant plant
species in the low tidal zone include hardstem bulrush and common bulrush. The middle tidal wetlands marsh provides foraging habitat for salt marsh harvest mouse and Suisun shrew, as well as common and special-status bird species, and shorebirds; this marsh zone also provides nesting and foraging habitat for Suisun song sparrow and salt marsh yellowthroat, and when inundated, for fish species. Dominant plant species in the middle tidal zone include pickleweed, saltgrass, and American bulrush. The high tidal wetland zone provides escape cover for salt marsh harvest mouse, Suisun shrew, California clapper rail during periods when the middle and low zones are inundated. The high marsh zone provides foraging and nesting habitat for special status species, such as salt marsh harvest mouse, and Suisun shrew; and provides foraging and nesting habitat for shorebirds, California clapper rail, California black rail, and other birds. Dominant plant species in the high tidal zone include saltgrass, pickleweed, annual grasses, baltic rush, and is critical habitat for special-status plant species such as, Suisun Thistle, Soft Bird's-beak, Suisun Aster, Delta Tule Pea, and Mason's Lilaeopsis. Sections 6.2 and 6.5 of the SMP EIS/EIR contain further information on tidal marsh vegetation and wildlife in the Marsh.

B. Suisun Marsh Plan Objectives

The Suisun Marsh Habitat Management, Preservation and Restoration Plan (SMP) is the result of a collaborative effort among federal, state, and local agencies working with scientists and the public to develop a plan to protect and enhance the Pacific Flyway and existing managed wetland values, natural wetland functions, tidal habitats, endangered species, water quality, and levee integrity. The SMP is a 30-year comprehensive plan that addresses habitats and ecological processes, public and private land use, levee system integrity, and water quality through tidal restoration and managed wetland activities. The SMP will guide near-term and future actions related to the various uses of the Marsh’s resources with the focus on achieving an acceptable multi-stakeholder approach to the restoration of tidal wetlands and the management of managed wetlands and their functions. As such, the SMP is a flexible, science-based, management plan for the Marsh, consistent with the revised Suisun Marsh Preservation Agreement (SMPA) and California Bay-Delta Authority (CALFED) Ecosystem Restoration Program Plan (ERPP) targets for the Suisun Marsh Ecological Management Zone, which will contribute to the US Fish and Wildlife Service’s (USFWS) Draft Recovery Plan for Tidal Marsh Ecosystems of Northern and Central California (Recovery Plan). The SMP will set the regulatory foundation for future actions, and relies on the incorporation of existing science and information developed through adaptive management.

The SMP’s purpose is to create an acceptable balance between protection and enhancement of managed wetlands, and the restoration and protection of tidal wetlands. As such, this adaptive management plan (AMP) targets multi-species benefits, rather than focusing on individual species. As described in Chapter 1 of the SMP EIS/EIR, the SMP objectives include:
Habitats and Ecological Processes – Implement the CALFED ERPP targets for the Suisun Marsh Ecological Management Zone by restoring 5,000 to 7,000 acres of tidal marsh and protection and enhancement of 40,000 to 50,000 acres of managed wetlands. Create an acceptable balance between protection and enhancement of managed wetland habitats for waterfowl and other resident and migratory wildlife species, and restoration and protection of tidal wetland habitat and other aquatic and terrestrial habitats in the Marsh to contribute to the recovery of threatened and endangered species, improve ecological processes, and reduce stressors such as invasive species and other contaminants.

Public and Private Land Use - Maintain the heritage of waterfowl hunting and other recreational opportunities and increase the surrounding communities’ awareness of the ecological values of the Marsh. Managed wetlands and publicly owned lands in the Marsh provide important wetlands for migratory waterfowl and other wetland-dependent species and opportunities for heritage hunting, bird watching, and other recreational activities.

Levee System Integrity – Maintain and improve Marsh levee system integrity to protect property, infrastructure, and wildlife habitats from catastrophic flooding; support tidal restoration; and maintain water quality standards in the Marsh and Delta; and

Water Quality – Protect and, where possible, improve, water quality for beneficial uses in the Marsh. Multiple factors contribute to the degradation of water quality in the Marsh, including some flooding and drainage practices in managed wetlands, minimal tidal exchange in dead-end sloughs, urban runoff, and naturally occurring contaminants such as mercury. Improvement of water quality and water management practices will benefit the ecological process for all habitats, including managed and tidal wetlands.

C. Role of Adaptive Management

Adaptive management is the process of learning by doing and then using the results to improve management actions (Walters and Holling, 1990). Figure 1a, at the end of this document, depicts the general adaptive management process. It also involves ongoing, real-time learning and knowledge creation. In an adaptive management approach, resource management and restoration policies are viewed as scientific experiments. This concept is important because the environmental outcomes of management policies are often uncertain. To be effective, decision-making processes must be flexible and designed to be adjusted in the face of uncertainties as outcomes from management actions and other events become better understood.

Adaptive management is essential to keeping the SMP on track toward its objectives, while avoiding and minimizing potential impacts associated with the
implementation of SMP actions. The information produced through adaptive management will permit changes to be made that will assist in the design of future steps. Adaptive management will assist project proponents in understanding the restored system and will aid in their ability to explain management actions to Marsh neighbors and the general public.

Restoration practitioners have found that, because knowledge of natural and social systems is incomplete, systems will respond in unexpected ways. Surprises are also inherent in restoration because nature is variable and unpredictable, especially at large spatial scales and over long time frames. Adaptive management allows managers to prepare for and respond to events, ranging from unexpected changes in habitat to vandalism. When and where such events occur may not be predictable, but part of the adaptive approach is to anticipate the range of events and system responses that might occur and develop a process for dealing with them when it happens. Monitoring and adaptive management can help to prevent unintended consequences of implementing actions under the SMP or, when they occur, can avoid unnecessary reoccurrence, help to minimize any negative impacts and address issues before they become substantial.

The SMP will occur over a 30-year implementation horizon. The SMP’s adaptive management approach will allow managers to learn from their actions and will:

- Generate science-based information for managers;
- Convert information into effective management decisions;
- Involve stakeholders to help provide management direction; and
- Store and organize information for use by current and future decision-makers and stakeholders.

This AMP has been prepared in accordance with the Department of Interior Adaptive Management Technical Guide (Williams et al. 2009) and uses the concepts of passive and active adaptive management. Through passive adaptive management, the Suisun Marsh Charter Principals Group will learn how to ensure better attainment of the SMP’s objectives based on the measured success of previous actions (as indicated by effectiveness monitoring results). The SMP will also take an active adaptive management approach by encouraging project proponents to identify uncertainties applicable to their specific project and carry out targeted studies to resolve uncertainties related to the best approaches for achieving project specific objectives. Project proponents could design and implement experimental pilot projects to test the relative efficacy of several approaches for attaining an objective and evaluate different monitoring techniques.

Project implementation will be guided by the best available information, but will be monitored and implemented with the goal of increasing our understanding about the
science of restoration. The opportunities for restoration and research are unknown due to the inability to predict where restoration projects will occur. As described in Chapter 1 of the SMP EIS/EIR, the SMP is consistent with the Recovery Plan in splitting restorable acreage into specific regions in order to provide a range of environmental gradients necessary to contribute to the recovery of multiple listed species. Implementation of the SMP Mitigation Monitoring and Reporting Program (Appendix F) will inform adaptive management decision making and tidal restoration planning efforts.

This AMP is designed to assist in achieving the SMP objectives by providing a guided approach to learning from restoration, research, monitoring and management actions, and actions which have uncertainties. Results of effectiveness monitoring may indicate that some restoration or management measures are less effective than anticipated. To address these uncertainties, the monitoring and adaptive management program will:

- Ensure impacts to benthic communities from dredging activities described and analyzed in the SMP EIS/EIR are not exceeded
- Gauge the effectiveness of restoration projects and techniques to implement SMP objectives
- Track project-specific targets to ensure restoration benefits listed species
- Propose alternative or modified measures as the need arises consistent with available funding and
- Be used to improve future restoration designs to achieve desired physical and ecological results;

As such, potential monitoring done under this AMP falls into two categories. The first category is monitoring required to ensure impacts analyzed in the EIS/EIR are not exceeded. Benthic community recovery monitoring during implementation of the dredging program as described in Chapter 2 of the SMP EIS/EIR is the only monitoring in this category. This benthic monitoring will be implemented by the Suisun Resource Conservation District (SRCD) and Department of Fish and Game (DFG) in accordance with the requirements of the USFWS and National Marine Fisheries Service (NMFS) Biological Opinions (Opinions) on the effects of the SMP.

The other potential category of monitoring that would occur under the SMP would be based on key uncertainties and would be considered for implementation as applicable for each tidal restoration project to assess project outcomes. Currently, monitoring in the Suisun Marsh is being carried out by a number of agencies and organizations (see Section II Monitoring). This monitoring will also provide additional information towards the key uncertainties.
D. SMP Conceptual Models and Uncertainties

During preparation of the SMP, conceptual models were developed for several resource categories, including managed wetlands, tidal marsh and aquatic habitat, levees, scalar transport and geometry, and water quality. These conceptual models have been developed to assist projects with information regarding the current scientific understanding of the Marsh, and identify uncertainties and potential actions. The models can be used to assist with selecting, designing, and predicting outcomes of project-specific design and objectives. These conceptual models include: Organic Matter, Mercury, Levee, Tidal and Aquatic, and Managed Wetlands, and are accessible at http://www.fws.gov/sacramento/ea/news_releases/2010_News_Releases/SuisunMP_EIS-EIR_DraftRelease.htm

Despite the extensive scientific information available, the SMP conceptual models identified a number of scientific uncertainties and knowledge data gaps that still exist. However, all the uncertainties cannot be resolved before restoration starts. In fact, many data gaps can only be addressed by implementing restoration actions and learning from the results. Therefore, these uncertainties form the basis for potential monitoring that could apply to specific restoration projects. Each restoration project will be unique and have distinct questions appropriate for monitoring or additional scientific studies. All new information gathered will be combined with existing monitoring data for the Marsh and collected to formalize knowledge, develop expectations of future conditions and outcomes that can be tested by further monitoring, and assess the likelihood of outcomes. Conceptual models are templates for organizing information and will require revision and updating based on monitoring results and new scientific knowledge. A list of uncertainties identified in the conceptual models that could be monitored as appropriate for specific tidal restoration projects can be found in the Attachment 1 of this AMP.

In addition to the resource-specific uncertainties identified in the conceptual models, climate change and changes to Delta outflow are two overarching long term uncertainties that have been identified and may affect the Marsh. The effects of rising sea levels on tidal marshes are dependent upon the relative rate of sea level rise versus rates of sedimentation and accretion of the marsh surface. Sea level rise will cause salinity levels to increase up the estuary as tides push higher up bays, rivers, and sloughs. The Suisun Bay and the Delta may become saltier. Closer study is needed of the potential amount and extent of salinity and habitat change, and the species-level effects of these changes. The maintenance of tidal marsh habitat area during sea level rise requires (1) space for tidal marshes to expand upward into adjacent habitats as sea and tide levels increase; (2) available sediment adequate to support marsh accretion rates equal to or greater than the rate of sea level rise; (3) stable erosion rates, or at least rates that do not defeat marsh
accretion. The first of these requirements - room for marshes to “move up” in elevation – is especially problematic in many areas of the San Francisco Bay Estuary where tidal marsh abuts a dike, levee, seawall, or other human barrier at its landward edge. The requirement for moderate erosion rates is also of concern, given that climate change and sea level rise in California are expected to be accompanied by increased storm severity and maximum wave heights; trends that are already suggested by available data (Wilkinson 2002, Bromirski et al. 2004). Sediment supply for marsh accretion is not yet well understood.

The State Water Project and Central Valley Project operations affect Suisun Marsh salinities by regulating Delta outflow through upstream reservoir storage and releases and Delta exports. As described in Chapter 1 of the SMP EIS/EIR, there are several other plans and policies currently being developed that have the potential to affect the Marsh. These plans are in varying stages of development, and details on how they would affect the Marsh are limited at this time. As information is made available for these uncertainties, it will be incorporated into tidal restoration planning efforts as appropriate in the future.

II. Monitoring

A. Ongoing monitoring

Monitoring is ongoing within the Marsh to varying degrees on public and private lands, and public waters. For example, the Interagency Ecological Program is comprised of state and federal agencies, as well as university and private scientists, who conduct long-term monitoring and applied research in the San Francisco Estuary directed towards effective management. Several ongoing monitoring programs currently exist in the Marsh:

- Salt Marsh Harvest Mouse Surveys: These surveys are conducted annually by DFG and DWR to monitor salt marsh harvest mouse populations.

- California Clapper Rail and Black Rail Surveys: These surveys are conducted annually by DFG to monitor clapper rail and black rail breeding pairs.

- Suisun Marsh Vegetation Surveys: These surveys are conducted every three years by DFG to monitor vegetation changes throughout the Marsh. An aerial survey is flown every three years and using GIS, produces a precise vegetation map with detailed descriptions of vegetation types. This survey is used to support monitoring of salt marsh harvest mouse and California clapper rail habitats, and can be used by private landowners to evaluate managed wetlands habitat response to management activities. Recently, this monitoring has included breach and channel network evolution for the Blacklock Tidal Restoration Project.
• Water Quality Monitoring: DWR maintains water quality and tide stage monitoring stations throughout the Marsh as part of the California Data Exchange Center (CDEC) monitoring network. These stations measure a variety of parameters depending on the station which may include precipitation, water temperature, wind speed and direction, and atmospheric pressure on an hourly basis. Data is telemetered to CDEC so tide stage can be monitored remotely.

• Interagency Ecological Program Database: This database contains data collected by UC Davis, DFG, and the USFWS, including: fishery, benthos, nutrient, pesticide, bioassay, water-weather condition, and survey fish tag data. (http://www.water.ca.gov/iep)

• Blacklock Restoration Project: This tidal restoration project has a monitoring plan which includes levee breach geometry, inundation regime monitoring, marsh surface elevation changes/sedimentation accretion, slough network evolution, native marsh vegetation, wildlife, water quality, methyl mercury, and erosion of adjacent sloughs.

• SRCD: DFG and Private Lands Reporting: Annually, SRCD compiles a summary report of actual annual managed wetlands maintenance work completed under the US Army Corps of Engineers Regional General Permit #3. In compliance with this permit, DFG and SRCD also conduct compliance inspections for diversion restrictions and submit report to the regulatory agencies.

• DFG Grizzly Island Wildlife Area: DFG conducts annual surveys for wintering waterfowl, and breeding surveys for tule elk, pheasant, and waterfowl.

• Audubon Society Christmas Bird Count: This data is collected annually to study long-term health and status of bird populations across North America. Surveys are conducted in the Marsh every year as the Benicia (CABE) count circle. http://birds.audubon.org/christmas-bird-count

• Tricolored Blackbird Surveys: These surveys are carried out every three years during April. DFG participates in this statewide survey coordinated by Audubon California. http://tricolor.ice.ucdavis.edu/

• Solano County Mosquito Breeding Habitat Monitoring - Adult mosquitoes are routinely monitored (7 night cycles) throughout the Solano County Mosquito Abatement District. Each week (from April through October) the samples are identified after which the findings are sent to the California Department of Health Services Vector Borne Disease Section (http://www.solanomosquito.com/aboutus.html).
In addition, several other monitoring programs are currently being implemented that could provide useful information in the adaptive management decision making process:

- **South Bay Salt Ponds Project:** USFWS is monitoring of similar restoration targets and objectives.
- **Dutch Slough Restoration Project:** DWR is monitoring fish hypotheses, water quality hypotheses, and miscellaneous bio-geomorphic hypotheses.
- **Napa River Salt Marsh Restoration Project:** DFG is monitoring wildlife use of evolving tidal habitats.
- **Bay Delta and Tributaries (BDAT):** BDAT contains environmental data concerning the San Francisco Bay-Delta and provides public access to that data. Over fifty organizations contribute data voluntarily to this project. The database includes biological, water quality, and meteorological data. These can be used to gauge the health of the estuary and to manage water.
- **UC Davis Fish and Invertebrate Study:** This monthly study uses multiple methods to sample fish in shallow, brackish-water habitat and has been designed since inception to monitor the status of fishes in the Marsh.
- **Time-Series Databases:** Hydrodynamics and water quality data of the California Bay-Delta Tributary collected by various agencies at over 120 stations (mostly fixed-position stations), using the data storage system which is suitable for time-series data and was developed by the Hydrologic Engineering Center of the US Army Corps of Engineers.
- **California Waterfowl Association:** Waterfowl nesting surveys are conducted on the Grizzly Island Wildlife Area to help monitor and assess waterfowl populations.

Information from these monitoring efforts is currently reported to the Suisun Environmental Compliance Advisory Team for use in agency planning efforts.

**B. SMP EIS/EIR Monitoring**

As previously mentioned, because there is scientific uncertainty regarding recovery times for benthic communities, SRCD and DFG will initiate a benthic community monitoring program concurrent with the implementation of the new dredging program in accordance with the USFWS and NMFS Opinions. The objectives of this monitoring are to determine benthic community richness and abundance prior to and following dredging at selected sites, with an extended post dredging component to determine species reestablishment of disturbed areas over an appropriate period of time. The purpose of this effort is to confirm the potential impacts of dredging on
benthic invertebrate communities in the vicinity of dredging activities and to make necessary adjustments to the dredging program to ensure that the anticipated effects as analyzed in the SMP EIS/EIR and biological opinions are not exceeded.

C. Potential Tidal Restoration Project Monitoring

Under the SMP each tidal restoration project will have its own specific objectives in support of the overall SMP tidal restoration objective of implementing 5,000 to 7,000 acres of tidal marsh restoration in the Marsh and contributing to recovery of listed species consistent with the Recovery Plan. Therefore, as applicable to project specific objectives, project specific monitoring will be recommended based on the previously described uncertainties during project planning and design. Project proponents will be responsible for implementing monitoring as incorporated into project planning documents. The approach for each restoration action will be determined by the specific lead agencies and will be based on the SMP EIS/EIR, project-specific design components, consideration of any new information (including that obtained through the implementation of the AMP), or other factors. Each project will create a monitoring plan that clearly identifies each monitoring activity, expected results, and responsible party for each monitoring activity.

During project monitoring planning, project proponents will:

- Assemble all available data
- Determine priorities
- Identify focal species or suites of species, if appropriate
- Identify performance indicators
- Develop monitoring protocols if none exist

To make monitoring useful, choices of ecological attributes to monitor and how to monitor them (frequency, extent, intensity, etc.), must be linked closely to the management situation that motivates the monitoring in the first place. There are always limits on staff and funding for monitoring, and it is important to choose design protocols that will provide the most useful information within those limits. Protocol design should be based on the purposes of monitoring and the way in which monitoring data will be analyzed.

Whenever possible, monitoring methods will be designed to collect data from multiple parameters. For example, aerial photographs or satellite images can show the extent of tidal marsh, connectivity of habitats, form and location of channels, and changes in invasive plant populations. After choosing parameters and methods, monitoring protocols must be used and, if not in existence, must be developed. These protocols must be designed to collect enough data at a scale and frequency
that allows managers to discern spatial differences and trends through time. Monitoring will be targeted at specific mechanisms thought to underlie measures and or actions and be used to assess results. Monitoring actions will be prioritized, and considerations should include feasibility of implementation, availability of funding, and uncertainty of outcome. Capturing baseline condition information, if it is not already available, will be a component of any project-specific monitoring plan.

There are several types of monitoring that would be implemented as part of tidal restoration projects under the SMP:

- Compliance monitoring would be built into project-specific permit requirements

- Performance monitoring would identify whether project-specific actions are achieving their expected outcomes or targets

- Mechanistic monitoring would demonstrate whether the mechanisms thought to link actions to desired outcomes are working as predicted.

Project monitoring needs to be designed to help reduce uncertainty, be measurable with observable responses to project implementation, noting that subtle differences in responses before and after project implementation are seldom detected. Tidal restoration project proponents will receive input from the Suisun Marsh Adaptive Management Advisory Team (AMAT) (further described in Section III) and Suisun Principals regarding project planning, design, and monitoring. In addition, it is recommended that each individual tidal restoration project seek the input of other science based work groups to develop goals, objectives, and performance measures for each restoration project, as applicable.

The following sections summarize categories for which key uncertainties have been identified (as listed in the previous section), and potential monitoring that could be recommended, as applicable, for specific tidal restoration projects. Further information on these uncertainties can be found in the appendix and in the conceptual models, as previously mentioned.

1. Managed Wetland Enhancement

There is scientific uncertainty regarding the potential effects of tidal restoration on species currently utilizing managed wetlands. As the SMP’s purpose is to create an acceptable balance between protection and enhancement of managed wetlands and the species that utilize them, and the restoration and protection of tidal wetlands, monitoring in this category will be crucial to balanced implementation of the SMP. Monitoring in this category will be closely integrated with existing monitoring efforts in the Marsh.
Objectives of this monitoring would include gaining information related to one or more of the following key uncertainties:

- Managed wetland enhancement effects on resident and migratory wildlife species and plant populations
- Regional waterfowl habitat availability and quality and the effects of managed wetland enhancement actions on indicators of waterfowl use

2. Tidal Restoration

The expected outcome of tidal restoration is the creation of marsh habitat for endangered soft bird’s-beak (Cordylanthus mollis ssp. mollis), endangered Suisun thistle (Cirsium hydrophilum var. hydrophilum), endangered California clapper rail (Rallus longirostris obsoletus) (clapper rail), and endangered salt marsh harvest mouse (Reithrodontomys raviventris) (harvest mouse) which will contribute to the recovery goals in the US Fish and Wildlife Service’s Suisun Bay Area Recovery Unit. There is uncertainty associated with the ways tidal restoration may change natural processes in unexpected ways during SMP implementation. Tidal marsh development will vary depending on its location within the Marsh.

Evaluating primary productivity at a tidal restoration site attempts to determine if a restoration project supports native fish species, including chinook salmon, delta and longfin smelt and other pelagic organisms by increasing the production of nutritionally valuable phytoplankton and zooplankton. An understanding of the magnitude of fish food production and release from restored tidal marshes in the Marsh is critical to determining the ability of restored intertidal marshes to aid in the recovery of pelagic species.

Objectives of this monitoring would include gaining information related to one or more of the following key uncertainties:

- Use of newly restored tidal habitats by special status plant and wildlife species
- Tidal restoration effects on resident and migratory wildlife species and plant populations
- Regional waterfowl habitat availability and quality and the effects of tidal restoration actions on indicators of waterfowl use
- Producer population growth in newly restored tidal habitats
- Nutrient cycling
• Zooplankton growth and availability in newly restored tidal habitats

• Native and non native fish habitat utilization and residence time in newly restored tidal habitats

3. Water Quality

Multiple factors contribute to the degradation of water quality in the Marsh, including increased salinities from tidal restoration projects, some flooding and drainage practices in managed wetlands, minimal tidal exchange in dead-end sloughs, urban runoff, and naturally occurring contaminants such as mercury. Improvement of water quality and water quality management practices will benefit ecological process for all habitats, including managed and tidal wetlands.

In cooperation with regional monitoring and research efforts, sediment and water quality monitoring could be conducted at several tidal restoration project sites. Ongoing information can be used adaptively to correct long-term construction and management plans and activities associated with restoration. Water quality parameters that could be monitored include salinity, temperature, dissolved oxygen, and methyl mercury.

Objectives of this monitoring would include gaining information related to one or more of the following key uncertainties:

• Carbon production with tidal restoration and potential for transport to Delta pumps and contribution to trihalomethane production

• Burial or exposure of existing mercury deposits in the Marsh

• Marsh biota exposure to mercury and reducing potential for methyl mercury exposure and transport in tidal restoration site design

• Effects of short term pulses of methyl mercury versus long term annual concentrations

4. Hydrodynamic Modeling

Hydrodynamic modeling is employed as a planning and predictive tool to investigate alternative breach options for tidal restoration projects. Hydrodynamic modeling at a planned and/or naturally occurring breach could be used as an indicator of outcome and a possible diagnostic tool to evaluate changes in tide stage, inundation regimes or increased salinities that were not anticipated. Cross sectional profiles of any additional natural breaches (of significant size) should be conducted where appropriate.
The previous sections describe a few examples of monitoring that could be implemented for tidal restoration projects under the SMP, based on key uncertainties identified in the conceptual models. However, this is not intended to be an all-inclusive list, and it is recognized that specific tidal restoration projects will have individual objectives and there may be monitoring for projects that is not captured here. Additional monitoring elements could include those developed for the Recovery Plan, the Bay Delta Conservation Plan Independent Science Advisors, or the Delta Stewardship Council. In addition, uncertainties not identified here could be realized during specific tidal restoration project design, and through information learned from completed tidal restoration project monitoring. Such information would be used to update the conceptual models and this AMP.

III. Adaptive Management Implementation

A. Roles and Responsibilities

To implement adaptive management, an effective decision-making structure must be developed to complete the loop between information from monitoring and the use of that information in decision-making. To be effective, decision-making processes must be flexible and designed to be adjusted in the face of uncertainties as outcomes from management actions and other events become better understood. The following structure has been collaboratively working on Marsh issues for over ten years and will continue through the implementation of the SMP. The structure for decision-making specific to the Suisun Marsh (Figure 1b at the end of this document) is designed to achieve these functions:

- Convert information into effective management decisions;
- Provide a forum for project development and collaboration;
- Involve the public/landowners to help provide management direction;
- Store and organize information for use by decision-makers and the public.

1. Suisun Marsh Charter Group Principals

The Suisun Marsh Charter Group Principal Agencies (Principals) have collaboratively prepared the SMP. The Principals include agency managers from DFG, DWR, Reclamation, USFWS, and SRCD that have experience with Marsh issues, policies, and permits. The Principal agencies are ultimately responsible for decisions that are implemented regarding the SMP. Projects will be reviewed for consistency with the SMP goals and objectives. The Principals and Adaptive Management Advisory Team (AMAT, described below) will work with agencies, such as the Regional Board and other resource agencies as appropriate, regarding marsh issues (e.g., water
quality). Principal agency actions related to the SMP are as follows, and are further described in the SMP.

### Principal Agencies’ Actions Related to the Suisun Marsh Plan

PAI = Preservation Agreement Implementation.
USFWS = U.S. Fish and Wildlife Service.
DFG = California Department of Fish and Game.
NMFS = National Marine Fisheries Service.
DWR = California Department of Water Resources.
SRCD = Suisun Resource Conservation District.
CALFED = CALFED Bay-Delta Program.

¹ The PAI Fund is included in the Revised SMPA and is proposed to fund certain maintenance activities to support mitigation obligations for the CVP and SWP operations, and is described in Chapter 2.

### 2. Adaptive Management Advisory Team (AMAT)

While project planning and design relies ultimately on the project managers for each restoration project, a network of staff from state and federal agencies will provide an interface for effective science, management, and outreach partnerships. The AMAT will be comprised of technical staff from DFG, DWR, SRCD, Reclamation, and USFWS, with invitations to other entities to participate as appropriate. The AMAT is guided by the AMAT Charter (Attachment 2), the purpose of which is to:

- Summarize the SMP objectives;
• Describe how the adaptive management process will be applied in the implementation of the SMP;

• Define the mission and objectives of the AMAT;

• Describe the relationship of the AMAT to the Principals and other groups; and,

• Define the core membership and the roles and responsibilities of the AMAT.

Project proponents are encouraged to use the AMAT and their knowledge of the Marsh for project development and support and as a forum to coordinate and cooperate for the benefit of the overall restoration goals. An MOU among the AMAT agencies will be pursued defining the roles and responsibilities of the members with respect to achieving the SMP objectives and implementing adaptive management. While retaining their existing individual land management authorities, project proponents will coordinate with the AMAT to develop project planning and design documentation, quantify specific restoration objectives and targets, and develop monitoring plans and schedules. Coordination with the AMAT does not preclude project proponents from their regulatory due diligence. No regulatory authority has been delegated to the AMAT. Each AMAT participating agency retains their own regulatory authority. The AMAT will coordinate with the Suisun Principals as appropriate.

The AMAT will:

• Provide access to detailed and updated conceptual models that synthesize existing knowledge of the Marsh

• Provide access to ongoing monitoring

• Review proponents’ projects, restoration targets, and monitoring plans

• Evaluate whether each project is contributing towards the overall SMP objectives

• Make recommendations for project additions or changes

• Conduct periodic reviews of project results

• Incorporate a feedback loop that links implementation and monitoring to a decision-making process
• Improve restoration designs to achieve desired SMP results

• Make recommendations to the Principal Agencies regarding implementation of the SMP

• Submit, every other year, an implementation status report to DFG, NMFS, USFWS and other regulatory agencies as required.

3. Information Management

As funding and staff become available for site specific projects, and in accordance with permit requirements (ie, biological opinions); data storage and access, including monitoring and/or GIS data, will be collected and made available to act as a link for planning future projects. The AMAT will be responsible for data storage and access, including monitoring and/or GIS data, and act as a link for all data collected. Data collected by this group will also include other relevant projects from around the Bay such as the San Francisco Bay and Napa Salt Ponds Restoration Projects. The AMAT will ensure that monitoring data and reports are made widely available, including to the Principal Agencies

4. Stakeholder Participation

Local stakeholder involvement is essential to meet the SMP objectives. Stakeholders will provide input to the AMAT to help guide restoration and adaptive management actions. The Stakeholder Group could include local public agencies, including SRCD; landowners; and other interested parties to provide on-going, local landowner-derived input to the Principals on adaptively managing implementation of the SMP.

B. Project Success Criteria

The U.S. Department of the Interior (USDOI) Adaptive Management Technical guide defines adaptive management as successful if progress is made toward achieving management goals through a learning-based (adaptive) decision process (Williams et. al. 2009). It also indicates that successful adaptive management: shows recognizable progress toward achieving objectives in a reasonable time frame, implements learning-based management with stakeholder involvement, and is consistent with all applicable laws and regulations. The SMP project success criteria is based on meeting the targets of restoring 5,000 to 7,000 acres of tidal wetlands habitat and protecting and enhancing 40,000 to 50,000 acres of seasonal wetland habitat.

Restoration of tidal wetlands is consistent with the Draft Recovery Plan for Tidal Marsh Ecosystems of Northern and Central California. The goal of the Draft...
Recovery Plan for Tidal Marsh Ecosystems of Northern and Central California is the comprehensive restoration and management of tidal marsh ecosystems in five recovery units; Suisun Bay, San Pablo Bay, the Central/South San Francisco Bay, Central Coast, and Morro Bay Recovery Units. Restoring 5,000 to 7,000 acres of tidal wetlands will aid in the recovery of the California clapper rail, salt marsh harvest mouse, Suisun thistle, and soft bird’s-beak with the Suisun Bay Recovery Unit.

Due to the long time frame for tidal marsh evolution and the difference in wildlife values of various types of tidal habitats, it is difficult to determine the end-point for project success. Projects related to, or tiered, from the SMP should incorporate post-construction monitoring and adaptive management to assess whether natural processes can sustain the long-term evolution of tidal marsh.

As elements and processes of managed wetland are constantly changing, adaptive management should be incorporated annually to track and determine the success of enhancement projects.

For each individual project tiered from the SMP a clear time line of monitoring would be developed in a manner to document results that would require a modification of the project, or identify possible new actions needed for the project to perform as intended.

C. Assessment of Monitoring Results

As it becomes available, the AMAT will review monitoring data for specific projects to assess how successful the individual tidal restoration projects are being at meeting their specific objectives. Also, the AMAT will annually review available monitoring data to assess progress towards achieving the overall SMP objectives. The AMAT will provide recommendations on additional monitoring needs and changes to restoration design based on review of past projects.

D. Feedback Loop and Decision Making

Technical learning will occur over a relatively short term, during which objectives, alternatives, and other elements remain unchanged. On the other hand, learning about the decision process itself will occur through periodic revisiting of the AMP elements over the longer term. The AMAT will primarily act as a feedback loop for new knowledge assimilated from ongoing actions and individual enhancement and restoration projects. An important role of the AMAT will be ensuring clear communication of the current understanding of existing baseline condition data to project proponents during the planning process. Also, the AMAT will provide a forum to advise project proponents of adverse conditions potentially impacting tidal restoration projects early in the planning process. As appropriate, the AMAT will advise the Principal Agencies of the need for changes to the SMP objectives and/or implementation strategy based on new information from project specific monitoring.
As described in the Implementation Strategy Section of Chapter 2 of the SMP EIS/EIR and as consistent with regulatory permits, the SMPA agencies (Reclamation, SRCD, DWR, and DFG) will submit implementation status reports no less frequently than every other year to DFG, NMFS, and USFWS, and other regulatory agencies that would describe the implemented restoration activities, monitoring, application of adaptive management, results of adaptive management, and any activities that are being planned.

**SMP Conceptual Model Uncertainties**

**Water Quality**

**Methylmercury/Contaminants**

Are existing mercury deposits in Suisun being buried or eroded?

Is the methyl mercury that is produced in the Marsh a source to the estuary or is the estuary a source to the Marsh?

Within the Marsh, where will the exposure of methyl mercury to biota be the highest? Managed wetlands, marshes, channels? Which species are most at risk?

If tidal wetlands are created how can the methyl mercury exposure to biota be minimized? How can export to surrounding marshes and/or sloughs be minimized?

Do the discharges from the managed wetlands that have low dissolved oxygen readings also have high methyl mercury concentrations and can the discharges be regulated to minimize the methyl mercury concentrations?

Are there habitats in Suisun which are better mercury methylators? Can we learn something from these that will be useful in tidal marsh restoration?

Do biota respond to periodic pulses of available methyl mercury or is it the longterm annual concentration that is critical?

Document the distribution and forms of mercury within the Suisun Marsh.

What are the mercury transport mechanisms in the Marsh?

Determine the mass balance of mercury and methyl mercury in the Marsh.

The relative contribution of methyl mercury production in managed wetlands and tidal wetlands has not been determined.

What are the methyl mercury concentrations in fish in the Marsh?

What factors influence methyl mercury production in the Suisun Marsh?

Is the oxic-anoxic sediment interface in a given wetland the primary factor in methyl mercury production?
Are existing total mercury concentrations known for the given location? Is mercury speciation known?

Will implementation of the alternative result in a change in the amount of oxic-anoxic interface in the sediments?

What is the toxicity of Ammonia/um to pelagic organism decline (POD) (Calfed Science Workshop 2009)?

Is implementation of the alternative likely to affect the level of activity of methylating bacteria (see Methyl Mercury Conceptual Model Table 1)?

What are the effects of pollutants on food production for wildlife?

What are the effects of managed wetland drainage water on ambient water quality?

What role do managed wetlands play in dissolved organic carbon and methylated mercury production?

What is the relationship between low dissolved oxygen events and management of wetlands?

**Fish and Wildlife**

What is the current use and density of species inhabiting managed wetlands?

Will enhancing current managed wetland functions aid multiple species?

Would it benefit listed species to allow wetland managers to manage specific sections of their property for them?

Would unrestricted access to water during fresh periods and saltier water later in the year benefit listed species?

What are the effects of tidal aquatic restoration on food web productivity at levels that could support fish and wildlife?

What is the waterfowl food availability and densities on managed wetlands?

What are waterfowl food preferences in Suisun?

What habitats do ducklings use and the effects of salinity on ducklings?

What are the effects of tidal restoration on waterfowl populations?
What are the Regional habitat availability effects on indicators of waterfowl use in Suisun?

Is it possible to increase the carrying capacity of managed wetlands for waterfowl under current regulatory restrictions?

Will increasing carrying capacity for wintering waterfowl on managed wetlands enhance other wildlife values?

What are the impacts of wetland management on birds nesting in wetland areas?

Evaluate the California clapper rail for effects of contaminants, connectivity, salinity, and use of dredge material to accelerate the restoration process.

Do fish screens affect foraging of waterbirds on managed wetlands?

Evaluate the Salt marsh common yellowthroat for connectivity, effects of non-native invasive plant species, inundation regime, and brown headed cowbirds.

Evaluate the Salt marsh harvest mouse for effects of other rodent species, non-native invasive plant species, connectivity, effects of contaminants, and geomorphology.

What are the effects of tidal restoration on salt marsh harvest mouse (SMHM)?

How do bat species use the Suisun Marsh?

What is the distribution of Suisun shrew on both managed and tidal wetlands of Suisun?

What impacts does wetland management have on the Suisun shrew?

What are the impacts to wetlands by wild pigs?

What are the effects of mosquito control and management on bat populations?

What are the impacts to fish species by drain water conditions (i.e. organic matter, low DO)?

What are the impacts to fish species by unscreened diversions with current regulations on diversions?

Would additional fish-screens address potential impacts to anadromous and special status fish in the Suisun Marsh?
Is fish entrainment in managed ponds temporary (fish return to sloughs) or permanent?

What is the abundance, distribution, and detailed species composition of submerged aquatic vegetation (SAV) in Suisun Marsh?

How do waterfowl and fish use SAV in Suisun Marsh?

Explore the effects of decreased habitat connectivity in the marsh due to the SMSCG and other water control structures on aquatic species such as delta smelt, longfin smelt, splittail, and resident native species.

Investigate effects of marsh geomorphology on delta smelt and longfin smelt use of Suisun Marsh.

Determine the importance of turbidity in comparison to other water quality parameters, to longfin smelt use of Suisun Marsh.

Evaluate the importance of invertebrate community composition to delta and longfin smelt use of Suisun Marsh.

Evaluate the Central Valley fall/late-fall, Sacramento River winter-run and Central Valley spring-run Chinook salmon for habitat utilization and residence time in the marsh.

Evaluate the Central California Coast and Central Valley steelhead for habitat utilization and residence time in the marsh.

Evaluate the Green sturgeon for habitat utilization, water quality preferences and residence time in the marsh.

Research is needed on determining effects of dredging on fisheries rearing, spawning, and migration habitat in tidal sloughs.

**Salinity**

What is the relationship between applied water salinity and plant community composition and growth (poor water salinity)?

What is the leaching efficiency of applied water?

Is salinity the primary driver of ecological functions in the Suisun Marsh?

What is the distribution of phytoplankton with regard to salinity?
Identify which levees are most important to the protection of local and regional salinity, and what are their critical design features.

**Subsidence**

What is the mechanism for subsidence?

Where is subsidence occurring in the Suisun Marsh?

Specifically, where in a managed pond does subsidence take place?

How much subsidence is there and at what rate does it occur in Suisun?

What is the importance of drying ponds in August to September?

What is the re-suspension of sediment by wind and wave action?

Does the placement of mineral sediment onto peat soil cause subsidence?

How do management strategies affect soil chemistry?

What is the relationship between internal recirculation of water and sedimentation?

What is the source of sediment in internal ditches?

What are the subsidence rates in the Suisun Marsh?

Would reduced discing frequency and reflooding fallow fields to maintain a high water table slow subsidence in the Suisun Marsh?

What are the long-term trends in sediment supply into Suisun Marsh and Bay from the Delta with projected sea level rise?

Research is needed on management practices that can reduce, eliminate, or mitigate for ongoing subsidence.

Research is needed to determine the cause as well as the individual and cumulative effect of subsidence and sea level rise on levee stability.

Current and continuing studies of sea level rise should consider the associated effects on levees in Suisun Marsh. Research is needed to determine if natural geomorphic processes, such as local or regional sediment accumulation or erosion, can benefit levee program elements to an extent that will counter local or regional sea level rise.
Levees

Would the construction of new interior levees within large wetland ponds improve flooding and draining capabilities?

Would the construction of new interior levees within large wetland ponds create new habitat for multiple species?

Would dividing some ponds into smaller cells (i.e. 50 to 100 acres) reduce the need for aerial mosquito abatement?

What is the effect of future sea level rise on managed wetland levee’s and management activities?

Research is needed to determine the beneficiaries for maintenance, improvements, and environmental costs of optimum designs and layouts for successful implementation. An evaluation of an incentive program that will encourage conservation practices and/or appropriate levee design and placement that can reduce overall programmatic cost, habitat impacts, and future risk is needed.

Additional research is needed as follow-up to the linkages identified by the CALFED Levee Program between the Suisun Marsh levee system configuration and water quality in the Delta. (CALFED Suisun Marsh Levees Investigation Report, March 2001)

Research on the design of levees with additional habitat features such as extended levee berms to provide opportunities to improve the level of flood protection and create needed habitat is needed. Research on the ability of dense vegetation growth on replacing the need for rip-rap is needed.

Evaluation of the potential use of newly established upland-like habitat levee areas by terrestrial vertebrate predators and what are impacts to species of concern is needed.

Additional research is needed to evaluate if larger initial environmental impacts may be offset in the long-term through reduced maintenance requirements associated with reinforced levee slopes. At the same time, research is needed to evaluate if the larger volume of material needed can be effectively supported by the existing underlying Marsh peat soils.

Research is needed in developing a strategy for utilizing dredge material collected within Suisun Marsh and from adjacent waterways as well as alternative sources.
Invasives

What are the threats posed by *Phragmites australis* in tidal marsh and adjacent shallow aquatic habitats?

What is the status of native versus non-native stands of common reed in invaded areas?

What is the potential for establishment of *Corbula* in restoration sites?

Processes

What are the causes of decline in phytoplankton biomass in Suisun?

What is the relative importance of different mechanisms relating river flow to chlorophyll concentration?

What is the ecological difference between shallow subtidal habitat from deep subtidal habitat?

How do changes in the abiotic or biotic structure of the marsh change the processes and functions of the marsh?

Do the shallow water habitats of diked wetlands provide an inundated floodplain value (e.g. Yolo bypass)?

Determine the characteristic population growth rate of producers in donor (title restoration) habitats.

Measure nutrient cycling in both high and low productivity habitats for evidence of nutrient limitation in productive habitats and possible export of reconstituted nutrients from respiration dominant habitats.

Investigate mechanical and metabolic constraints on zooplankton growth as a function of food availability.
Attachment 2

Adaptive Management Advisory Team Charter for the
Suisun Marsh Habitat Management, Preservation and Restoration Plan

May 9, 2013

I. Background

The Suisun Marsh Habitat Management, Preservation and Restoration Plan (SMP) is a 30-year comprehensive plan that addresses habitats and ecological processes, public and private land use, levee system integrity, and water quality through tidal restoration and managed wetland activities. The SMP’s purpose is to create an acceptable balance between protection and enhancement of managed wetlands and the restoration and protection of tidal wetlands (SMP Final EIR/EIS, Volume II, Appendix E, Page E-4).

The SMP was developed and will be overseen by the Suisun Principal Agencies (the Principals). These agencies are the U.S. Fish and Wildlife Service (USFWS); U.S. Department of Interior, Bureau of Reclamation (Reclamation); California Department of Fish and Wildlife (DFW); California Department of Water Resources (DWR); National Marine Fisheries Services (NMFS); Suisun Resource Conservation District (SRCD); and the Delta Stewardship Council (successor to the CALFED Bay-Delta Program).

Guiding Principles for SMP Implementation

1. The SMP will be implemented through the application of adaptive management.
2. The SMP Adaptive Management Plan targets multi-species benefits rather than focusing on individual species.
3. The SMP will be implemented in a manner consistent with the 1977 Suisun Marsh Preservation Act, Suisun Marsh Preservation Agreement (SMPA), the Department of Fish and Game’s Ecosystem Restoration Program (ERP) Conservation Strategy, the U.S. Fish and Wildlife Service’s Draft Recovery Plan for Tidal Marsh Ecosystems of Northern and Central California, and the Delta Stewardship Council’s Delta Plan (expected to be adopted in 2013).

II. Purpose of the Charter

The SMP states that adaptive management is essential to keeping the SMP on track toward its objectives and minimizing potential impacts associated with the implementation of SMP actions (SMP Implementation Strategy, p. 65). The SMP Adaptive Management Plan calls for the formation of an Adaptive Management Advisory Team (AMAT). The purpose of the AMAT Charter is to:

- Summarize the SMP objectives;
- Describe how the adaptive management process will be applied in the implementation of the SMP;
- Define the mission and objectives of the AMAT;
- Describe the relationship of the AMAT to the Principals and other groups; and
- Define the core membership and the roles and responsibilities of the AMAT.
III. SMP Objectives

The SMP objectives may be summarized as follows:

1. Restore 5,000 to 7,000 acres of tidal marsh to contribute to the recovery of threatened and endangered species.
2. Protect and enhance 40,000 to 50,000 acres of managed wetlands to benefit waterfowl and other resident and migratory wildlife species.
3. Improve ecological processes and reduce stressors, such as invasive species and contaminants.
4. Maintain waterfowl hunting heritage and expand opportunities for hunting, fishing, bird watching, and other nature-oriented recreational activities.
5. Maintain and improve Marsh levee system integrity.
6. Protect and, where possible, improve water quality for beneficial uses in the Marsh.

(For the full description of the SMP objectives, see the SMP Final EIR/EIS, Volume II, Appendix E, Page E-5.)

IV. Definition of Adaptive Management in the Context of the SMP

The SMP Adaptive Management Plan (SMP Implementation Strategy, Appendix A) defines adaptive management as “the process of learning by doing and then using the results to improve management actions (Walters and Holling, 1990).” The SMP Adaptive Management Plan further states that adaptive management “involves ongoing, real-time learning and knowledge creation. In an adaptive management approach, resource management and restoration policies are viewed as scientific experiments.” (SMP Final EIR/EIS, Volume II, Appendix E, Page E-5)

The SMP Implementation Strategy calls for passive and active adaptive management (SMP Final EIR/EIS, Volume II, Appendix E, Page E-6), described as follows:

- Through passive adaptive management, the Principals will learn how to ensure better attainment of the SMP objectives based on monitoring the effectiveness of management actions.
- Active adaptive management will involve the Principals encouraging project proponents to carry out targeted studies to resolve uncertainties related to the best approach to achieving specific objectives.

The Principals will, where appropriate, use the adaptive management framework presented in the Draft Delta Plan. The Draft Delta Plan describes the adaptive management process as shown in Figure 1. This process will be applied, as appropriate, at both the landscape scale and the project scale.
V. AMAT Mission Statement

The mission of the AMAT is to support the Principals in using adaptive management, including use of best available science, to achieve the SMP objectives. This will be accomplished by staffing the AMAT with technical experts who will provide guidance to project proponents and the Principals. The members of the AMAT are discussed later in Section VII below.
VI. Relationship of the AMAT to the Principals and Other Groups

The Principals will:

- Establish the AMAT by drafting and signing a memorandum of understanding among participating agencies and directing their technical staff to participate in the AMAT;
- Review projects for consistency with the SMP goals and objectives (SMP Final EIR/EIS, Volume II, Appendix E, Page E-16);
- Determine whether a proposed habitat restoration project in the Suisun Marsh can be expected to help achieve the habitat goals of the SMP based on input from the AMAT;
- Request that the agencies with responsibility for issuing permits for tidal restoration projects in the Suisun Marsh facilitate permit coordination by convening regular meetings with permit applicants;
- Facilitate coordination of monitoring for regulatory compliance and to support adaptive management, with guidance from the AMAT; and
- Use the information, analysis and synthesis provided by the AMAT to adapt implementation to better achieve the SMP objectives.

Project proponents will:

- Seek review of project design and the adaptive management plan from the AMAT, If the project proponent intends to tier from the SMP environmental documents and the Principals determine that the project will help achieve the objectives of the SMP;
- Apply for all necessary permits from the regulatory agencies; and
- If applicable, request habitat mitigation credits from the appropriate groups, such as the Fisheries Agency Strategy Team (FAST), which handles habitat crediting for the Fish Restoration Program Agreement (FRPA) and the Bay Delta Conservation Plan early implementation projects.

(Coordination with the AMAT does not preclude project proponents from their regulatory due diligence. Each AMAT participating agency retains its own regulatory authority. No habitat mitigation crediting authority has been delegated to the SMP Principal Agencies or the AMAT.)

Revised SMPA Agencies. To track the progress of restoration and managed wetland activities, the Revised Suisun Marsh Preservation Agreement agencies (Reclamation, SRCD, DWR, and DFW) will submit implementation status reports no less frequently than every other year to DFW, NMFS, and USFWS, and other regulatory agencies that would describe the implemented restoration activities, monitoring, application of adaptive management, results of adaptive management, and any activities that are being planned (SMP Final EIR/EIS, Volume II, Appendix E, Page E-20).

Delta Science Program. The Delta Science Program (DSP) will support the AMAT by working with others to develop a landscape-scale conceptual model for the Suisun Marsh, building upon existing resource specific conceptual models developed for the SMP (SMP Final EIR/EIS, Volume II, Appendix E, Page E-8). The Delta Science Program will coordinate with the SMP to:
• Identify uncertainties associated with the conceptual model and assist in seek funding and in-kind contributions to accomplish studies and analysis to reduce uncertainties.
• Determine how information gained from project-specific monitoring can be used to reduce uncertainties in the landscape-scale conceptual model.
• Use the landscape-scale conceptual model to inform implementation of the SMP and serve as the repository for what is learned.

The DSP will assist project proponents by providing early consultation on project design and adaptive management plans for restoration projects that are covered actions under the Delta Plan. The DSP will also support SMP implementation through the development of the Delta Science Plan, which will be a shared plan that organizes and integrates ongoing scientific research, monitoring, analysis, and data management for the Delta science community. The Delta Science Plan will recommend approaches for an integrated monitoring approach, data management and accessibility, shared computer models, and synthesis of scientific knowledge.

ECAT. The Principals and the AMAT will coordinate with other programs with jurisdiction in or focus on the Suisun Marsh, such as the Environmental Coordination and Advisory Team (ECAT). The ECAT’s responsibilities include: (1) ensuring compliance with mitigation and monitoring requirements of the Revised SMPA, related permits, and biological opinions, and (2) provide technical guidance and oversight of Suisun Marsh monitoring, management, and restoration programs conducted as part of the SMPA (page 26 RSMPA). Monitoring data collected and reports generated by the ECAT may provide useful inputs to the performance measures that will be used to track progress toward achieving the SMP objectives.

VII. Membership, Roles and Responsibilities of the AMAT

The AMAT will be comprised of technical staff from DFG, DWR, SRCD, Reclamation, USFWS, NMFS, and the Delta Stewardship Council, with invitations to other technical experts (i.e., Delta Science Program staff) to participate as appropriate. These seven agencies serve as the Core AMAT Members and have primary responsibility for implementation of the AMAT Charter. The other technical experts may be drawn from public agencies, academia, research institutes, non-profit organizations and the private sector.

The AMAT will guide adaptive management at the landscape and project scale.

LANDSCAPE-SCALE ADAPTIVE MANAGEMENT

For the purposes of this Charter, landscape-scale adaptive management refers to adaptive management at the scale of the geographic area covered by the Suisun Marsh Plan.

Roles of the AMAT in Landscape-Scale Adaptive Management

1. **Coordinate with the Delta Science Program in its Development of a Landscape-Scale Conceptual Model for the Suisun Marsh.** During preparation of the SMP, conceptual models were developed for several resource categories, including managed wetlands, tidal marsh and aquatic habitat, levees, scalar transport and geometry, and water quality. These conceptual models have been developed to assist projects with information regarding the current scientific understanding of the Marsh, and identify
uncertainties and potential actions. The models can be used to assist with selecting, designing, and predicting outcomes of project-specific design and objectives (SMP Final EIR/EIS, Volume II, Appendix E, Page E-8). Coordinating with the AMAT and building upon the existing conceptual models, the Delta Science Program will work with others to develop and continually refine a landscape-scale conceptual model for Suisun Marsh based on the best available science (Draft Delta Plan, Ecosystem Chapter, Science Needs section). During the development of the landscape scale conceptual model, the AMAT will proceed with project review using existing conceptual models.

2. **Pursue Research to Address Key Issues.** Conduct research and pilot projects to address key issues, such as fish and wildlife recovery, subsidence reduction and reversal, and water quality, as ecologically appropriate opportunities and associated funding become available.

3. **Advise Principals in Using Performance Measures to Track Plan Implementation.** Advise the Principals in developing performance measures to track progress toward achieving the SMP objectives such as acreage of tidal marsh restored, abundance of waterfowl and listed species, water quality, etc.
   - Advise in the development of standardized monitoring protocols.
   - Advise in data management to facilitate easy access to the full range of existing monitoring data, including ECAT data.
   - Report, at a minimum, yearly to the Principals, other resource managers and stakeholders, on progress in implementing the SMP, based on the performance measures. Include a synthesis of whether the restoration projects are producing the outputs and outcomes expected and a status update on the progress made toward the SMP objectives.

4. **Advise in Adaptive Management of the Suisun Marsh Plan.** As appropriate, advise the Principals of the need for changes to the SMP objectives and/or implementation strategy based on new information (SMP Final EIR/EIS, Volume II, Appendix E, Page E-20).
   - Work with the Delta Science Program to facilitate periodic independent scientific review of SMP implementation (SMP Implementation Strategy, page 66).

**PROJECT-SCALE ADAPTIVE MANAGEMENT**

As described above, before the AMAT becomes involved in guiding the adaptive management of a proposed restoration project, the Principals must determine whether the project will fall under the purview of the SMP. The screening process consists of the following steps:

1. The project proponent determines whether s/he intends to use the SMP environmental documents rather than developing project-specific environmental documents.
2. The project proponent will be required to consult with the AMAT in the development of a monitoring and adaptive management plan for the project. The AMAT will also provide project design review.
3. The Principals may also request that agencies with permit authority convene a regulatory group to facilitate coordination of permit requirements for restoration projects. The group may request input
from the AMAT on monitoring parameters and adaptive management actions to include in permit conditions.

Roles of the AMAT in Restoration Projects

1. Review tidal restoration project designs and advise project proponents on how to increase chances of achieving project objectives and minimize adverse effects, based on lessons learned from ongoing and completed projects.

2. Review monitoring and adaptive management plans. Advise on the use of standardized monitoring protocols where possible. Help each project proponent develop a monitoring program tailored to the purpose of the project in order to enable evaluation of project success, and designed to address scientific uncertainties in order to help inform future restoration projects. Provide input to regulatory agencies on monitoring needed to track project performance.

3. Review project monitoring reports and evaluations of project success. Draw conclusions regarding success or failure of projects. Determine lessons learned and conditions under which those lessons are applicable for future restoration actions and updating the landscape-scale conceptual model.

VIII. AMAT Operations

The AMAT will meet quarterly, at a minimum, and it may hold additional meetings as appropriate. The AMAT will have an appointed chairperson from one of the core member agencies, as defined in Section VII above, and the position will rotate to a different agency every two years. Notes from each AMAT meeting will be prepared, and will include a summary of the meeting discussions, record any decisions made, and identify action items with schedules. The AMAT will utilize an internet-based data portal for information sharing and progress tracking.

IX. Updates to the Charter

The AMAT Charter may be updated as necessary.
General Adaptive Management Process

1. Define/redefine the problem
2. Establish goals & objectives
3. Model linkages between objectives & proposed action(s)
4. Select action(s): research, pilot, or full-scale
5. Design & implement action(s)
6. Design & implement monitoring plan
7. Analyze, synthesize & evaluate
8. Communicate current understanding
9. Adapt

Evaluate and respond

Plan

Implement
Once a site specific project is identified the project proponent would define or redefine the problem and goals and objectives would be established for that site.

#### Noise

Comply with local noise regulations by limiting construction to the hours specified by Solano County when construction activities occur near residences.

When it is determined through site-specific analysis that construction has the potential to occur near residences, the following noise-reduction practices will be implemented:

- use electrically powered equipment instead of internal combustion equipment where feasible;
- locate staging and stockpile areas and supply and construction vehicle routes as far away from sensitive receptors as possible;
- establish and enforce construction site and haul road speed limits;
- restrict the use of bells, whistles, alarms, and horns to safety warning purposes;
- design equipment to conform to local noise standards;
- locate equipment as far from sensitive receptors as possible;
- equip all construction vehicles and equipment with appropriate mufflers and air inlet silencers;
- restrict hours of construction to periods permitted by local ordinances; and
- locate redirected roadways away from sensitive receptors.

If any areas with pickleweed or vegetation within 50 feet of the edge of pickleweed need to be cleared for project activities, vegetation shall be removed only with non-mechanized hand tools (i.e., trowel, hoe, rake, and shovel). No motorized equipment, including weed whackers and lawn mowers, shall be used to remove this vegetation. Vegetation shall be removed under the supervision of a qualified biologist approved by DFG and USFWS. If a mouse of any species is observed within the areas being removed of vegetation, DFG and USFWS shall be notified. Vegetation removal may begin when no mice are observed and shall</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
RESTORATION ACTIVITIES

- start at the edge farthest from the salt marsh or the poorest habitat and work its way toward the salt marsh or the better salt marsh habitat;
- Removal of vegetation in wetland habitat will be conducted with a qualified biological monitor present. This monitor will watch for special-status wildlife species and temporarily stop work if special-status species are encountered. Wildlife will be allowed to escape before work is resumed. Monitors with the appropriate qualifications to handle special-status species will be allowed to move special-status species to safe locations as permitted by their authorizations; and
- Temporarily affected wetlands will be restored by removing construction-related debris, and trash. Affected areas will be seeded with a seed mix of local native wetland species.

Prepare and implement an environmental resources worker training program.

Project proponents will provide training to field management and construction personnel on the importance of protecting environmental resources. Communication efforts and training will be done during preconstruction meetings. Construction personnel will be educated on the types of sensitive resources located in the project area and the measures required to avoid impacts on these resources. Materials covered in the training program will include environmental rules and regulations for the specific project and requirements for limiting activities to the construction right-of-way and avoiding demarcated sensitive resources areas. Training seminars will educate construction supervisors and managers on:

- the need for resource avoidance and protection;
- construction drawing format and interpretation;
- staking methods to protect resources;
- the construction process;
- roles and responsibilities;
- project management structure and contacts;
- environmental commitments, and
- emergency procedures.

If new construction personnel are added to the project, the contractor will ensure that the personnel receive the mandatory training before starting work. A representative will be appointed during the employee education program to be the contact for any employee or contractor who might inadvertently kill or injure a listed species or who finds a dead, injured, or entrapped individual. The representative’s name and telephone number will be provided to the USFWS before the initiation of ground disturbance.

<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Perform preconstruction surveys for California clapper rail and California black rail if construction activities are necessary during the breeding season as follows:

- Surveys will be conducted at and adjacent to areas of potential tidal and managed wetlands habitats for California clapper rail and black rail;
- Surveys will focus on potential habitat that may be disturbed by construction activities during the breeding season to ensure that these species are not nesting in these locations. Survey methods will follow the protocols used by DFG during previous rail surveys in Suisun Marsh (California Department of Fish and Game 2007). The specific project proponent will implement the following survey protocols:
  - Surveys should be initiated sometime between January 15 and February 1. A minimum of four surveys should be conducted. The survey dates should be spaced at least 2 to 3 weeks apart and should cover the time period from the date of the first survey through the end of March or mid-April. This will allow the surveys to encompass the time period when the highest frequency of calls is likely to occur;
  - Listening stations will be established at 150-meter intervals along road, trails, and levees that will be affected by plan implementation;
  - California clapper rail and California black rail vocalization recordings will be played at each station;
  - For California clapper rails, each listening station will be occupied for a period of 10 minutes, followed by 1 minute of playing California clapper rail vocalization recordings, then followed by an additional minute of listening;
  - For black rails, each listening station will be occupied for 1 minute of passive listening, 1 minute of “grr” calls followed by 30 seconds of “ki-ki-krrr” calls, then followed by another

</tbody>
</table>

- **3.5 minutes or passive listening:**
  - Sunrise surveys will begin 60 minutes before sunrise and conclude 75 minutes after sunrise (or until presence is detected);
  - Sunset surveys will begin 75 minutes before sunset and conclude 60 minutes after sunset (or until presence is detected);
  - Surveys will not be conducted when tides are greater than 4.5 National Geodetic Vertical Datum (NGVD) or when sloughs and marshes are more than bankfull; and
  - California clapper rail and California black rail vocalizations will be recorded. A GPS receiver will be used to identify call location and distance. The call type, location, distance, and time will be recorded on a data sheet.

If California clapper rail or black rail is present in the immediate construction area, the following measures will apply during construction activities:

- To avoid the loss of individual California clapper rails or black rails, activities within or adjacent to California clapper rail or black rail habitat will not occur within 2 hours before or after extreme high tides (6.5 feet or above, as measured at the Golden Gate Bridge), when the marsh plain is inundated, because protective cover for California clapper rails is limited and activities could prevent them from reaching available cover;

- To avoid the loss of individual California clapper rails or black rails, activities within or adjacent to tidal marsh areas will be avoided during the California clapper rail breeding season from February 1 through August 31 each year unless surveys are conducted to determine California clapper rail locations and California clapper rail and black rail territories can be avoided. Figure 2–5 shows the areas of known clapper rail breeding habitat;

- If breeding California clapper rails or black rails are determined to be present, activities will not occur within 700 feet of an identified calling center. If the intervening distance across a major slough channel or across a substantial barrier between the California clapper rail calling center and any activity area is greater than 200 feet, it may proceed at that location within the breeding season.

- **Exception:** Only inspection, maintenance, research, or monitoring activities may be performed during the California clapper rail or black rail breeding season in areas within or adjacent to California clapper rail breeding habitat with approval of the USFWS and DFG under the supervision of a qualified biologist.

### Power Production and Energy

None

### Visual/Aesthetic Resources

For projects that have the potential to affect views or create a new source of light or glare, identify sensitive view receptors for site-specific analysis and ensure that contractors minimize fugitive light from portable sources used for nighttime operations. In addition, a visual barrier will be installed to prevent light spill from truck headlights in areas with sensitive view receptors.

### Cultural Resources

Immediately cease work within 100 feet inadvertent discoveries of cultural resources, including human remains. All construction personnel will leave the area. Vehicles and equipment will be left in place until a qualified archaeologist identifies a safe path out of the area. The on-site supervisor will flag or otherwise mark the location of the find and keep all traffic away from the resource. The on-site supervisor immediately will notify the lead state or federal agency of the find.

Comply with Native American Grave Protection and Repatriation Act (43 CFR 10) if inadvertent discovery of Native American remains occurs on federal lands.

Comply with state laws relating to the disposition of Native American burials (Public Resources Code [PRC] 5097 and California Health and Safety Code 7050.5[b]) for human remains discoveries on non-federal lands.

If human remains of Native American origin are discovered during ground-disturbing activities on non-federal land, the lead state or federal agency must comply with state laws relating to the disposition of Native American burials, which fall within the jurisdiction of the Native American Heritage Commission (NAHC) (PRC 5097). If human remains are discovered or recognized in any location other than a dedicated cemetery, the lead state or federal agency will not allow further excavation or disturbance of the site or any nearby area reasonably suspected to overlie adjacent human remains until:

- the Solano County coroner has been informed and has determined that no investigation of the cause of death is required; and
- if the remains are of Native American origin,

- Pipe replacement as well as repair, replacement, or installation of exterior water control structures will not change the existing use or diversion capacity;
- All pipes will be pre-assembled before installation to minimize work time;
- All material shall remain on the crown or interior side of the levee during the repair of exterior existing levees, the coring of existing exterior levees, and the installation of drain pumps and platforms;
- All bulkheads will be in place prior to backfilling the bulkhead during installation, repair, or re-installation of water control structures;
- Installation of drain pumps and platforms will be done entirely within the managed wetland; although discharge pipes will comply with permit terms and conditions for exterior discharge pipe installation;
- All work to be performed on the exterior side of levees shall commence and be completed within a 6-hour period, from 3 hours prior to low tide to 3 hours after low tide;
- Construction equipment used for projects will be checked each day prior to work and, if necessary, action will be taken to prevent fluid leaks. If leaks occur during work, the Corps, its permittee, or the contractor will contain the spill and remove the affected soils;
- All contractors must have a supply of erosion and pollution control materials on site to facilitate a quick response to unanticipated storm events or emergencies;
- No in-water work will occur during the repair of existing exterior levees; the coring of existing levees; pipe replacement at the exterior flood or dual-purpose gate; pipe replacement at the existing exterior drain gate; installation, repair, or re-installation of water control bulkheads; installation of drain pumps and platforms; or installation of new exterior drain structures;
- Emergent vegetation will not be disturbed during the following activities: repair of existing exterior levees, replacement of existing riprap on exterior levee, or installation of the new exterior drain structure; and
- No fresh concrete, cement, silts, clay, soil, or other materials will be discharged to Marsh waters.

Prepare and submit monthly work reports to the Corps, NMFS, State Lands Commission, and the RWQCB.

Prepare and submit an annual activities summary report to the Corps, U.S. Environmental Protection Agency, NMFS, USFWS, State Lands Commission, and the RWQCB.

### MANAGED WETLAND ACTIVITIES

- Suisun thistle (*Cirsium hydrophilum* var. *hyrdophilum*);
- Suisun Marsh aster (*Aster lentus*);
- alkali milk-vetch (*Astragalus tener*);
- heartscale (*Atriplex cordulata*);
- brittlescale (*Atriplex depressa*);
- valley spearscale (*Atriplex joaquiniana*)

If a special-status plant is found during a survey, it should be avoided, and a map showing the location of the plant should be provided to DFG, the Corps, and USFWS no later than 7 calendar days after the survey is completed. If a special-status plant cannot be avoided during the proposed work and it is not listed as threatened or endangered, the plant will be carefully transplanted to the nearest suitable habitat provided this action and the proposed transplantation site are determined by DFG to be adequate to offset any impact. If approved by DFG, a qualified representative of Suisun Resource Conservation District (SRCD) or DFG may conduct the transplantation. If DFG does not determine that transplantation will offset the impact, a restoration plan will be prepared and implemented, after DFG approval, that will be able to ensure that impacts on the plant population are offset. This determination by DFG will include an assessment of species distribution, the abundance in the Marsh, and the level of proposed impact.

If a federally listed threatened or endangered plant is found that cannot be avoided during the proposed work, the qualified representative of SRCD or DFG will notify the Corps immediately so it can consult with the USFWS. If determined necessary by USFWS and if a federally listed plant cannot be avoided during the proposed work, the plant will be carefully transplanted to the nearest suitable habitat provided this action and the proposed transplantation site is determined by USFWS to be adequate to offset any impact. If approved by USFWS, a qualified representative of SRCD or DFG may conduct the transplantation. If USFWS does not determine that transplantation will offset the impact, a restoration plan will be prepared and implemented, after USFWS approval, that will be able to ensure that impacts on the plant population are offset. This determination by USFWS will include an assessment of species distribution, abundance in the Marsh, and the level of proposed impact.
