

RECLAMATION

Managing Water in the West

Site Inventory and Hydropower Energy Assessment of Reclamation Owned Conduits

*Supplement to the “Hydropower Resource
Assessment at Existing Reclamation Facilities
Report”*

U.S. Department of the Interior
Bureau of Reclamation
Power Resources Office
Denver, Colorado

March 2012

Mission Statements

The mission of the Department of the Interior is to protect and provide access to our Nation's natural and cultural heritage and honor our trust responsibilities to Indian Tribes and our commitments to island communities.

The mission of the Bureau of Reclamation is to manage, develop, and protect water and related resources in an environmentally and economically sound manner in the interest of the American public.

Site Inventory and Hydropower Energy Assessment of Reclamation Owned Conduits

*Supplement to the “Hydropower Resource
Assessment at Existing Reclamation Facilities
Report”*

Acknowledgments

This report was sponsored by the Bureau of Reclamation's Power Resources Office; however several individuals were instrumental in developing the data and analysis for this study. We wish to acknowledge the following Reclamation staff for their support: Robert Ross, William Cole, Tom Ryan, Don Bryce, Neil Anderson, Clark Bishop, Talmadge Oxford, and Brian Campbell. We would also like to acknowledge staff at Idaho National Laboratory (INL) who played a critical role in providing guidance, analysis, and review of the site assessments. The INL staff that contributed to this report were: Doug Hall, Todd Haynes, and Joseph Petersen.

Background

On March 24, 2010, the Department of the Interior, the Department of Energy, and the Department of Army entered into a Memorandum of Understanding (MOU) with the purpose of enhancing the coordination of their efforts to provide the Nation with affordable, reliable, and environmentally sustainable hydropower. This Hydropower MOU consists of numerous initiatives including an action item to conduct Federal facility energy resource assessments, and under this direction Reclamation conducted a study called the *Hydropower Resource Assessment at Existing Reclamation Facilities* (Resource Assessment) that gauged hydropower development potential at existing Reclamation facilities. This study was published in March 2011, and is available for download at (<http://www.usbr.gov/power>).

The Resource Assessment updated the Reclamation portion of the “Potential Hydropower Development at Existing Federal Facilities” study completed in May 2007 under Section 1834 of the Energy Policy Act of 2005 (1834 Study). While the 1834 Study satisfied the requirements of Sec. 1834, it did not include many small and low head sites due to several screening processes.

The updated Resource Assessment utilized the 530 identified sites in the 1834 Study, but analyzed the hydropower potential of all of those sites regardless of size. Additionally, the Resource Assessment incorporated updated economic and technical analyses including detailed turbine selections, green incentives, proximity to transmission, and analysis of regulatory/environmental constraints. Of the 530 identified sites, 191 were determined to have some level of hydropower potential, and 70 of those sites showed some economic potential to be developed.

The Resource Assessment shows that approximately 268 MW and 1.2 million MWh of energy could be produced annually at existing Reclamation facilities if all 191 sites with the technical potential for development were developed. A total of 225MW of installed capacity and 1.0 million MWh of energy could be produced annually at existing Reclamation facilities if all sites with a benefit cost ratio greater than 0.75 were developed.

The Resource Assessment, however, did not fully capture the hydropower potential of all Reclamation conduits. For example, a large portion of the canals that were listed in the 1834 Study did not identify a specific drop or drops in the canal and simply listed the head differential along the entire stretch of the canal (sometimes over tens of miles). Elevation changes in canals and tunnels can occur over short or long distances and field investigations were needed to determine net head. Additionally, not all canal drops were identified in the 1834 Study, and the scope of the Resource Assessment did not include site visits for evaluating new sites. Further study outside of the scope of the Resource Assessment was necessary to clearly identify canal sites and their hydropower

potential. As a result, Reclamation embarked on a phase II study called the “Site Inventory and Hydropower Energy Assessment of Reclamation Owned Conduits, a Supplement to the Hydropower Resource Assessment at Existing Reclamation Facilities”, (“Supplemental Assessment Report”).

Concurrent to Reclamation’s study of hydropower potential on conduits, Idaho National Laboratory’s Water Energy Program (INL) was tasked with identifying hydropower potential on conduits across the Nation. Under the auspices of the 2010 Hydropower MOU, Reclamation and INL worked together to produce this report.

Purpose

This Supplemental Assessment Report builds off of the Resource Assessment, and identifies potential hydropower sites on Reclamation owned conduits and determines those sites’ capacity and energy potential. In addition, this study identifies proximity to distribution/transmission lines, and provides site maps for the identified sites.

Considerations for Developers

Although Reclamation reserves the right to develop hydropower at non-powered Reclamation sites, this report can aid irrigation districts, cities, municipalities, cooperatives and other nonprofit organizations financed through the Rural Electrification Act of 1936 in their decision making process to determine whether further analysis of a site’s hydropower potential may be warranted. As with any non-federal hydropower development on Reclamation facilities, existing project water deliveries must not be negatively impacted by a proposed hydropower project. Protections to ensure that water deliveries would not be negatively impacted would be addressed in either a Lease of Power Privilege or a Federal Energy Regulatory Commission (FERC) License and would at a minimum include requirements that the project be designed to ensure continued water delivery in the event of a powerplant outage. Since Reclamation owned conduits are often operated and maintained by local irrigation districts, it is highly recommended that developers involve those stakeholders in the project.

Licensing jurisdiction for hydropower development at Reclamation facilities is held with either Reclamation through its Lease of Power Privilege process or FERC through its licensing and exemption procedures. Licensing jurisdiction is dependent on the authorizing legislation for the respective project, and jurisdiction for any particular project would be determined in accordance with procedures established pursuant to an existing Memorandum of Understanding between Reclamation and FERC. In some cases existing statutes, contracts or agreements grant power development rights or preference to entities at a specific project.

Data Collection

Hydropower sites on conduits consist of elevation drops in canals, pipelines and tunnels where head can be captured to generate power; or at a turnout or siphon used to move water from a larger canal into laterals or smaller canals for delivery. Since Reclamation owns approximately 47,336 miles of canals, laterals, drains, pipelines and tunnels, many of them with little head or flow, it was determined that the first step was to create feasibility guidelines on hydropower potential. Based on discussions with low-head turbine manufacturers, hydropower developers, and Reclamation staff a reasonable minimum head for a technically feasible micro-hydropower project was determined to be 5 feet. Additionally, it was determined that only sites with at least 4 months of operations per year that could produce 50 kW of capacity based on gross head and the maximum flow capacity of the canal (design flow) would be identified in this report. To calculate the necessary design flow to produce 50 kW at each head range a power calculation of $\text{Flow [cfs]} = \text{Power [kW]} * 11.8 / \text{Head [feet]}$ was used.

To locate and identify potential drops on Reclamation owned conduits, Reclamation staff researched project drawings, aerial imagery, utilized expertise from local area officials, and in some cases physically visited the canals. While an attempt was made to identify all sites, it is possible that additional unidentified conduit sites exist. Sites identified in this report consist of a variety of structure types, including:

- Check Structures - Check structures are used to raise the upstream water surface elevation to permit flow diversion through upstream turnouts. Some check structures can be used to measure the flow rate within a canal. When a check structure is introduced into a canal a unique relationship between the upstream water surface and the downstream water surface is established as a function of the channel geometry and flow rate through the canal.
- Vertical Drops - Vertical drops are used to describe a structure that enables a change in elevation over a very short length of canal alignment.
- Chutes - Chutes are usually used where water is conveyed over long distances and along grades that may be flatter than those for drops but steep enough to maintain sufficient velocities.
- Series of Drops - This categorization is used to describe multiple vertical drops structures located in series. The head listed is the difference from the highest point in the alignment to the lowest point.
- Pipelines - A pipeline is a closed conduit structure used to convey water.
- Check drops - Check drops are used to describe a vertical drop structure with a check structure integrated on the upstream end.

Report Content

To identify the available flows at each site, Reclamation and irrigation district personnel provided seasonal, monthly or daily flow information when available. Actual flows occurring in Reclamation conduits are variable, and while the design flow was useful in screening for possible sites, it is not very reliable when looking for the actual energy and capacity potential of a site because it may significantly overestimate a site's potential.

Flow records through canals and tunnels are often recorded and monitored by Reclamation or U.S. Geological Survey (USGS) gages, but Reclamation also contacted local irrigation districts, local authorities or irrigation districts for additional flow data. In some instances local districts had electronic or hard copy flow data, and these flow data were used for the analysis. In other cases, local officials provided monthly or seasonal estimates for average flow at these sites.

Since the availability of flow data varied per site, it is important to understand the level of precision of the data used to calculate the capacity and energy potential at each site. For many sites, historical daily data were available, and in these cases there was a high level of confidence in its accuracy because the daily, seasonal and annual variability of flows were clearly captured. For sites where historic daily data were not available it was necessary to rely on local knowledge for typical flows. When monthly average flows were used there was less precision in the data, but some of the annual variability in the canal operations were still captured. For sites where local area knowledge of seasonal averages was used, the data confidence level and the corresponding confidence in the capacity and energy results are lower. The level of data utilized for each site is provided in the tables below.

In many cases, site visits to the canals were conducted to confirm the site location, available head, and whether any distribution lines were in the immediate vicinity. It should be noted that while proximity to distribution lines is identified, it is outside of the scope of this report to make a determination regarding whether these distribution lines were sufficient to interconnect to a new hydropower facility.

Every site that was sent forward by the Reclamation field offices was assigned an Object ID to easily track the data; however not all of the sites that were sent forward had the necessary head or design flow to be included in the final results. Additionally, some sites that were sent in as individual sites were combined into a single site after discussions with the area offices. 128 sites were removed from the report for these reasons but are catalogued in Appendix A.

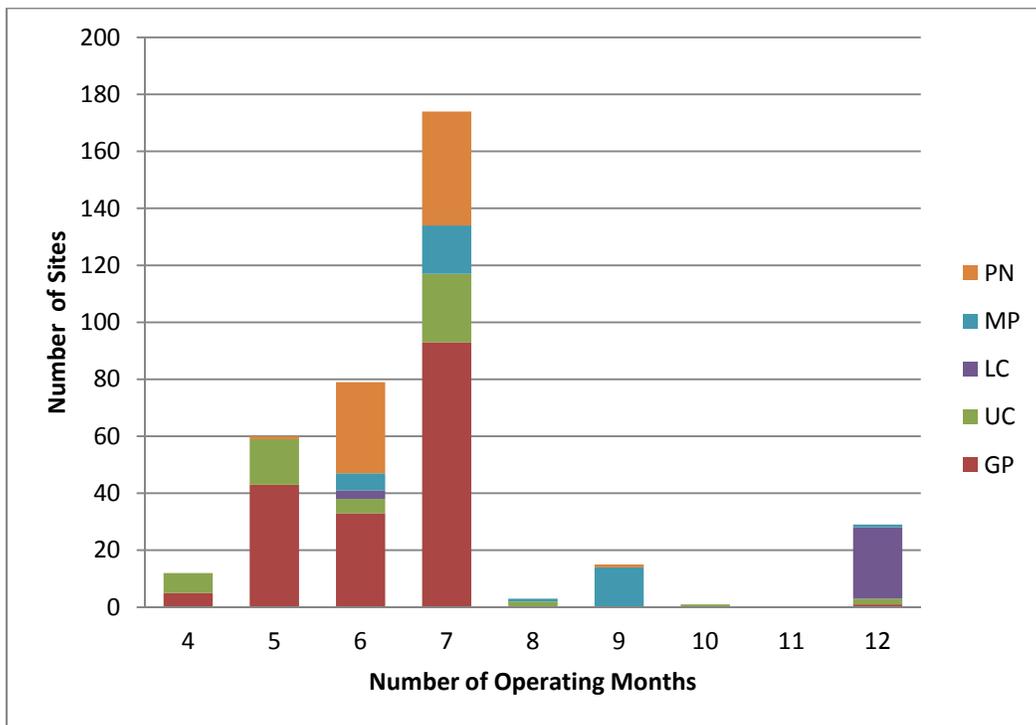

Additionally, flow estimates were not available for 44 of the identified sites. For these sites the capacity and energy potential were not able to be calculated. These sites, including the available information on head and the maximum canal design flow, are catalogued in Appendix B.

Data Analysis

When sufficient data were collected on site location, head, flow and access to distribution lines these data were processed utilizing the Hydropower Assessment Tool and site maps were created.

The Hydropower Assessment Tool is designed to size a plant by utilizing a 30% flow exceedance to eliminate unusual flow events and to act as a first cut at sizing a plant economically to capture the most constant flow. Different exceedance percentages can be selected for sizing the hydropower plant, which could increase or decrease the plant capacity. Changing the plant capacity would effectively change the amount of energy the plant can generate and also change the costs to develop, operate, and maintain the plant. This 30% exceedance is appropriate as a first cut for the majority of hydropower sites, but Reclamation conduits are primarily operated for irrigation purposes and most of these conduits only have seasonal flows. Graph 1 below displays the breakdown of the identified sites and their typical number of operating months and indicates that the vast majority of sites identified in this report operate for 7 months or less. Due to this seasonality, it was determined through discussions with INL and Reclamation staff that it would be appropriate to lower the flow exceedance for this analysis to 15%. This allowed for the capture of more of the seasonal flow, and captured more of the available energy and capacity at all sites.

Graph 1: Seasonality of Sites by Region

As was demonstrated in the Resource Assessment, most sites that operate seasonally do not have positive benefit cost ratios for hydropower development since the generators sit idle for large periods of time during the year. Since the Hydropower Assessment Tool was designed using broad economic assumptions associated with developing hydropower using conventional technologies it may not necessarily capture all of the site specific benefits of developing seasonal small hydropower on a conduit. For instance, in remote locations where pumping plants are needed to move water, transmission expenses can be very large and hydropower development may decrease the costs of providing power for these pumping loads. Additionally, new technologies are being developed and deployed specifically for small conduit hydropower. This could significantly decrease the costs of development, operation and maintenance at these sites and subsequently increase their economic viability.

As a result of the factors listed above, the Supplemental Assessment Report focuses on identifying the technical potential of hydropower development based on each site's available head, flow, and proximity to transmission/distribution lines, but does not provide an economic benefit cost analysis. The report identifies capacity and generation potential; as well as site maps, the number of months of potential generation for each site¹, and their proximity to transmission or distribution lines.

Data Quality Assurance

After INL and Reclamation processed data through the Hydropower Assessment Tool, Reclamation conducted a thorough review of the data and model results, including a review of the site maps, reported head, reported flow, modeled capacity and modeled energy results of each identified site. A listing of site specific head and flow notes for each site is included in Appendix C.

Results

The results of this study show that 103,628 kW of potential capacity and 365,218,846 kWh of potential generation are available at 373 identified sites on Reclamation canals.

As shown on Table 1, although sites were identified in every Reclamation region, the sites identified in this report with the highest energy generation potential are in the Great Plains, Upper Colorado and Pacific Northwest regions.

¹ "Number of months of potential generation" counts a month if more than 2% of the potential annual generation occurs in that month.

Table 1: Energy and Capacity by Region

Region	Canal Sites	Potential Installed Capacity (kW)	Potential Annual Energy (kWh)
GP	175	38,525	122,204,196
LC	28	5,239	29,283,867
MP	39	4,392	17,550,289
PN	74	22,755	85,385,703
UC	57	32,717	110,794,792
Total	373	103,628	365,218,846

Sites were identified in 13 of the 17 western states, but as shown on Table 2 approximately 70% of the capacity and energy potential on Reclamation owned conduits is located in Colorado, Wyoming and Oregon.
