Registering Bed Load Impacts on the Riverbed for Surrogate Bed Load Measurement

Quantifying coarse bed load transport rates at fixed cross sections of a riverbed

Problem
Measuring how gravel and rocks move along a riverbed is a critical component for understanding a river’s geomorphology, which is needed to understand the channel morphology for better prediction of sediment transport. This is especially crucial downstream from a dam removal to determine how channels form—and where very little sediment measurement data exist.

Quantifying the movement of bed sediment in a river (the bed load) is difficult because bed load moves only during high flow events, perhaps once a year under normal conditions. Measuring bed load transport using classical means, with pressure difference bed load samplers, only provides snapshots (1 to 2 minutes) of data at discrete times and locations across the channel and is dangerous during floods. To truly understand bed load transport, a reliable way to continuously measure its movement is needed.

To perform continuous measurements, a series of bed load impact plates have been installed on the Elwha River for measuring bed load during and after dam removal. Each plate is instrumented with either a geophone (46 plates) or accelerometer (26 plates). Either sensor can be used to quantify bed load. These instrumented steel plates are mounted adjacent to one another and span the active channel.

While these plates can measure the signals generated as bed load moves across them, the signals need to be interpreted. Characterizing bed load based on these signals requires understanding these signals—which signals indicate what amount and type of sediment movement?

Bottom Line
This research project will help determine the appropriate signal processing from impact plates instrumented with an accelerometer to provide an alternate means to measure bed load on the Elwha River using plates. The impact plate system is currently measuring bed load with geophones.

Better, Faster, Cheaper
Physical measurements of bed load are dangerous and expensive. This technology could provide continuous, safe measurements critical for designing and protecting infrastructure and habitat.

Solution
To date, the impact plate system has had a preliminary calibration for the impact plates instrumented with geophones. In 2015, this Reclamation Science and Technology Program research project performed flume experiments with a full-scale two-plate system instrumented with accelerometers. These experiments were done in cooperation with the U.S. Department of Agriculture’s Agricultural Research Service and the University of Mississippi’s National Center for Physical Acoustics. These experiments will provide valuable information regarding the best method to process the accelerometer signals to quantify bed load transport and possibly determine particle size.

Future Plans
Future efforts include additional physical bed load measurements (spring 2016) for in situ calibration of the accelerometer plates and additional calibration information for the geophone plates.
