Figure 1. Screen layout for 20:1 velocity ratio

Figure 2. Screen layout for 10:1 velocity ratio
Test Methods

- Three trials each were conducted with two types of debris (Duckweed and Elodea) for each flow condition tested.
- Five to seven pounds of debris, drained and weighed before each trial, were introduced into the flume for each trial;
- Debris is left in flume for an additional 10 minutes before the flow was shut down.
- At the completion of each trial, debris collected from the return channels was weighed and documented. Video and photos were also used to document each trial.
Wedgewire and Perforated Plate Screens Tested at a 20:1 Ratio

$V_{sweep} = 4 \text{ ft/s}$, $V_{approach} = 0.2 \text{ ft/s}$

Wedgewire screen tested with Elodea at a velocity ratio of 20:1.

Perforated plate screen tested with Duckweed at a velocity ratio of 20:1.
Perforated Plate Tested at a 10:1 Ratio
$V_{sweeping} = 4.0 \text{ ft/s}$, $V_{approach} = 0.4 \text{ ft/s}$

Figure 5. Perforated plate screen is covered by a thin mat of Duckweed at a velocity ratio of 10:1.

Figure 6. Perforated plate screen tested with Elodea at a velocity ratio of 10:1.
Perforated Plate Tested at a 10:1 Ratio

\[ V_{\text{sweeping}} = 2.0 \text{ ft/s}, \quad V_{\text{approach}} = 0.2 \text{ ft/s} \]
Large Debris Removal from Positive Barrier Screens

Leslie Hanna
Water Resources Research Laboratory
Debris removal

- Vertically rotating conveyor (with fingers) is positioned between screen panels to remove large debris along positive barrier screens

Model Study Objectives

- Determine most effective finger configuration (i.e. geometry, positioning and material) and conveyor speed for removing large debris, while not interfering with fish migration
