

# Project L: Overflight Remote Sensing in Support of Long-Term Monitoring and LTEMP

Joshua Caster, Joel B. Sankey,  
Nathaniel Bransky and David Dean

*GCDAMP Annual Reporting Meeting*

*This information is preliminary and is subject to revision. It is being provided to meet the need for timely best science. The information is provided on the condition that neither the U.S. Geological Survey nor the U.S. Government shall be held liable for any damages resulting from the authorized or unauthorized use of the information.*

# Talk Outline

1. Project L Update
2. Research Application (*Caster Dissertation*)

# Project L Goals

## Project Element L.1. Analysis and Interpretation of Overflight Remote Sensing Data

- GCMRC Triennial Workplan (TWP) Project L FY2024/25/26/27  
Budget \$352k/\$291k/\$315k/\$332k
- *Imagery and derivative data products from overflight remote sensing are used either directly or indirectly by every science project proposed in the TWP to address every resource goal of the LTEMP*

# Project L Goals

## Project Element L.1. Analysis and Interpretation of Overflight Remote Sensing Data

### Science Questions (FY25 – 27 TWP):

- How have the system-wide area and volume of high elevation sand (LTEMP performance Metric 7.3) changed?
- Do system-wide remote sensing measurements provide a comprehensive metric of dam-related changes influence
  1. Riparian vegetation cover (LTEMP performance Metric 11.1)
  2. Other land covers
  3. Management activities, climate, or other environmental factors in the ecosystem

# Project L Science Activities

## Land cover classification for 2021 imagery

- ◇ ~8,000 ft/s discharge stage (base flow conditions during May 2021 imagery)
- ◇ Total riparian cover
- ◇ Sand and other river sediment

# Talk Outline

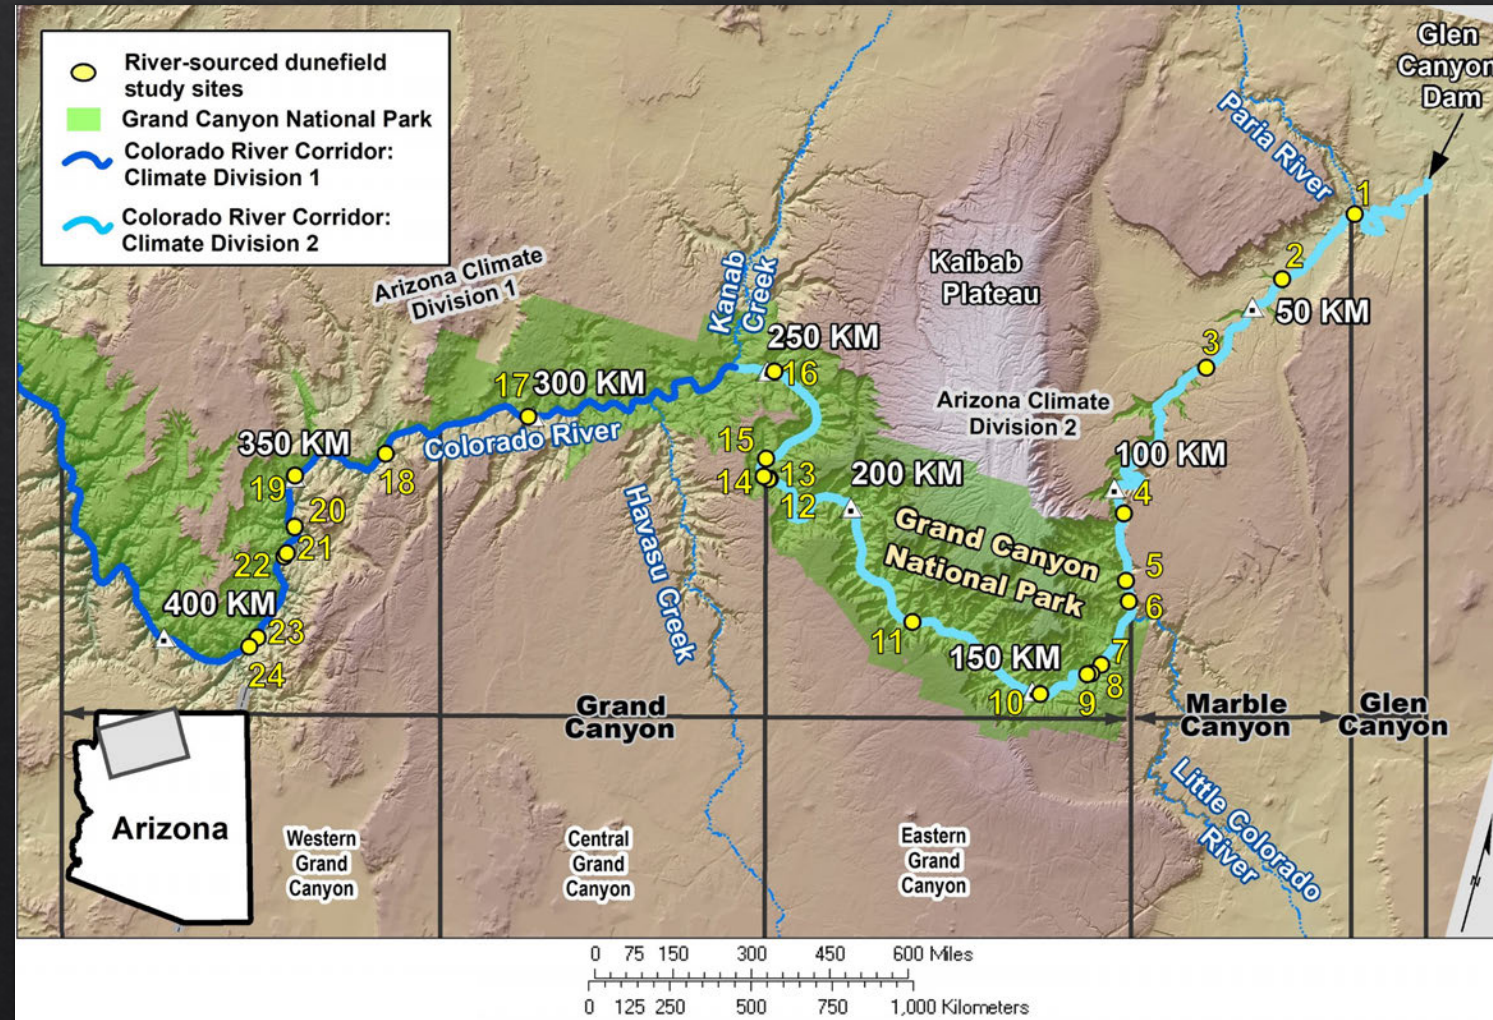

1. Project L Update
2. Research Application (Caster Dissertation)

# Evaluating long-term topographic changes in river-sourced aeolian sand (*Caster, 2024*)

PhD Dissertation (not funded by GCDAMP) using overflight remote sensing data:

How are high-elevation sands within aeolian dunefields changing over decades of river management?

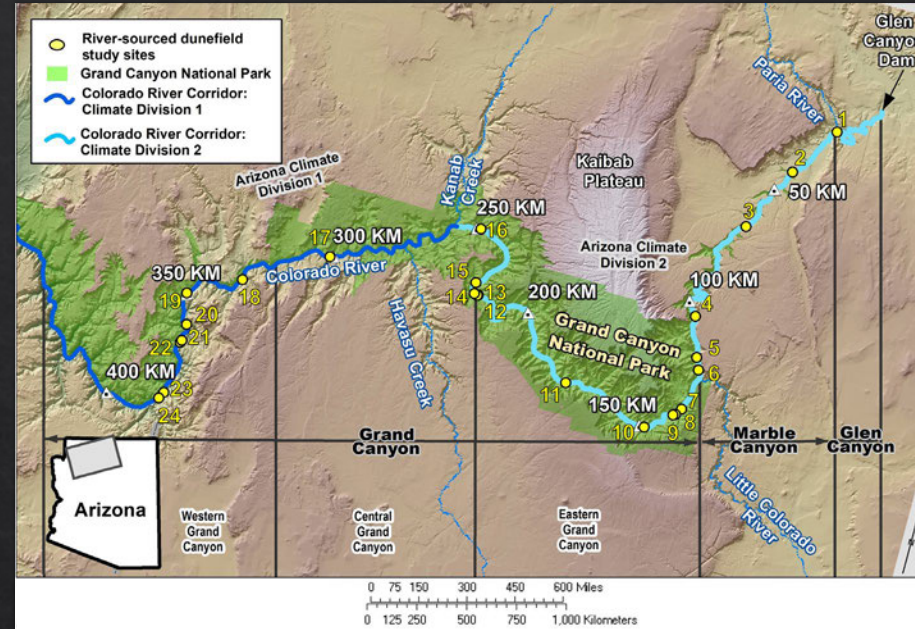

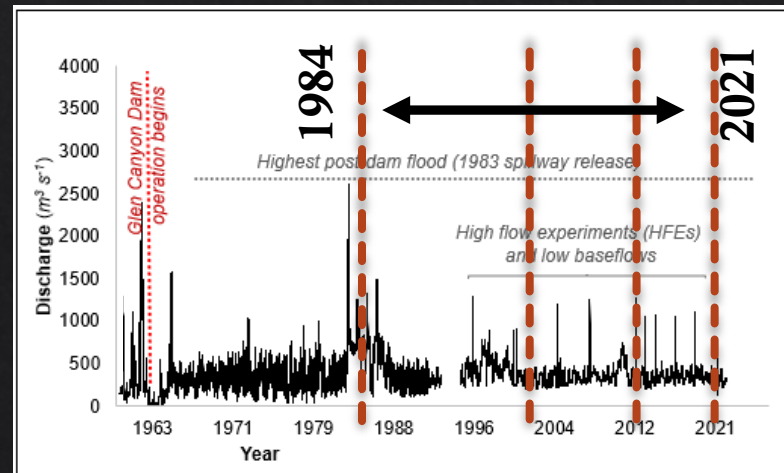

# Evaluating long-term topographic changes in river-sourced aeolian sand (*Caster, 2024*)

How are high-elevation sands within aeolian dunefields changing over decades of river management?

- 2002 -2021 Digital surface models (*Published by Project L*)
- Produced new topographic dataset from 1984 imagery

24 locations  
(All of which are monitored as part of either Project B or D)

Almost 4 decades of changing river operations and topography

# Changes between 1984 – 2021: In context

# Changes between 1984 – 2021: In context

# Changes between 1984 – 2021: In context

# Changes between 1984 – 2021: In context

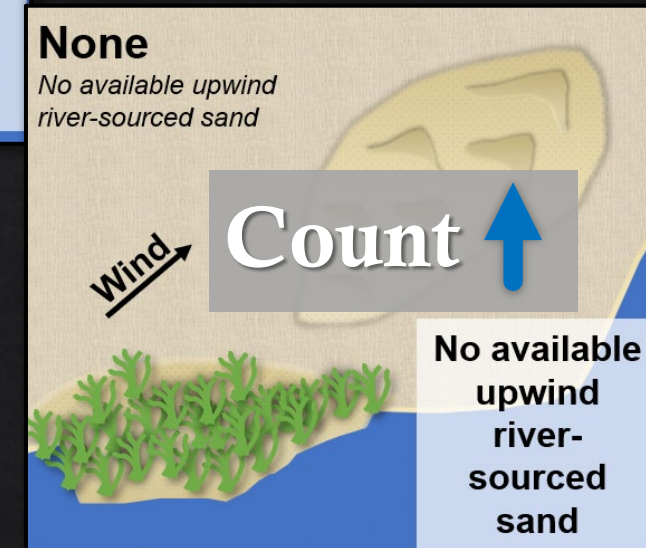

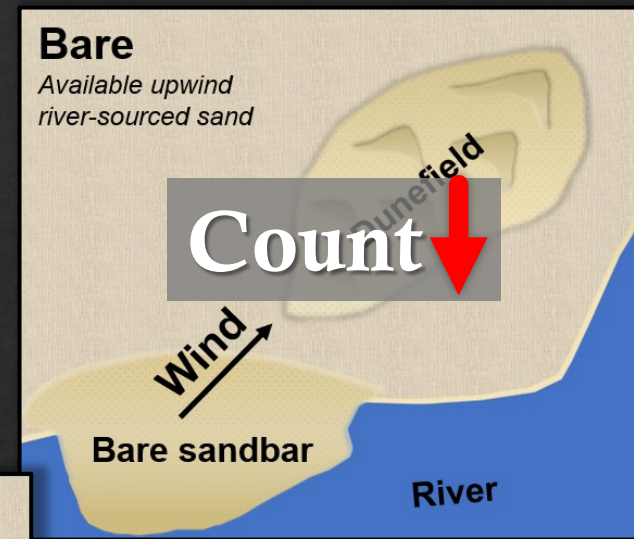

# Research Question (*Caster Dissertation*)

As the river and adjacent landscape become disconnected...

...do river-sourced sands in dunefields above the active channel measurably respond?

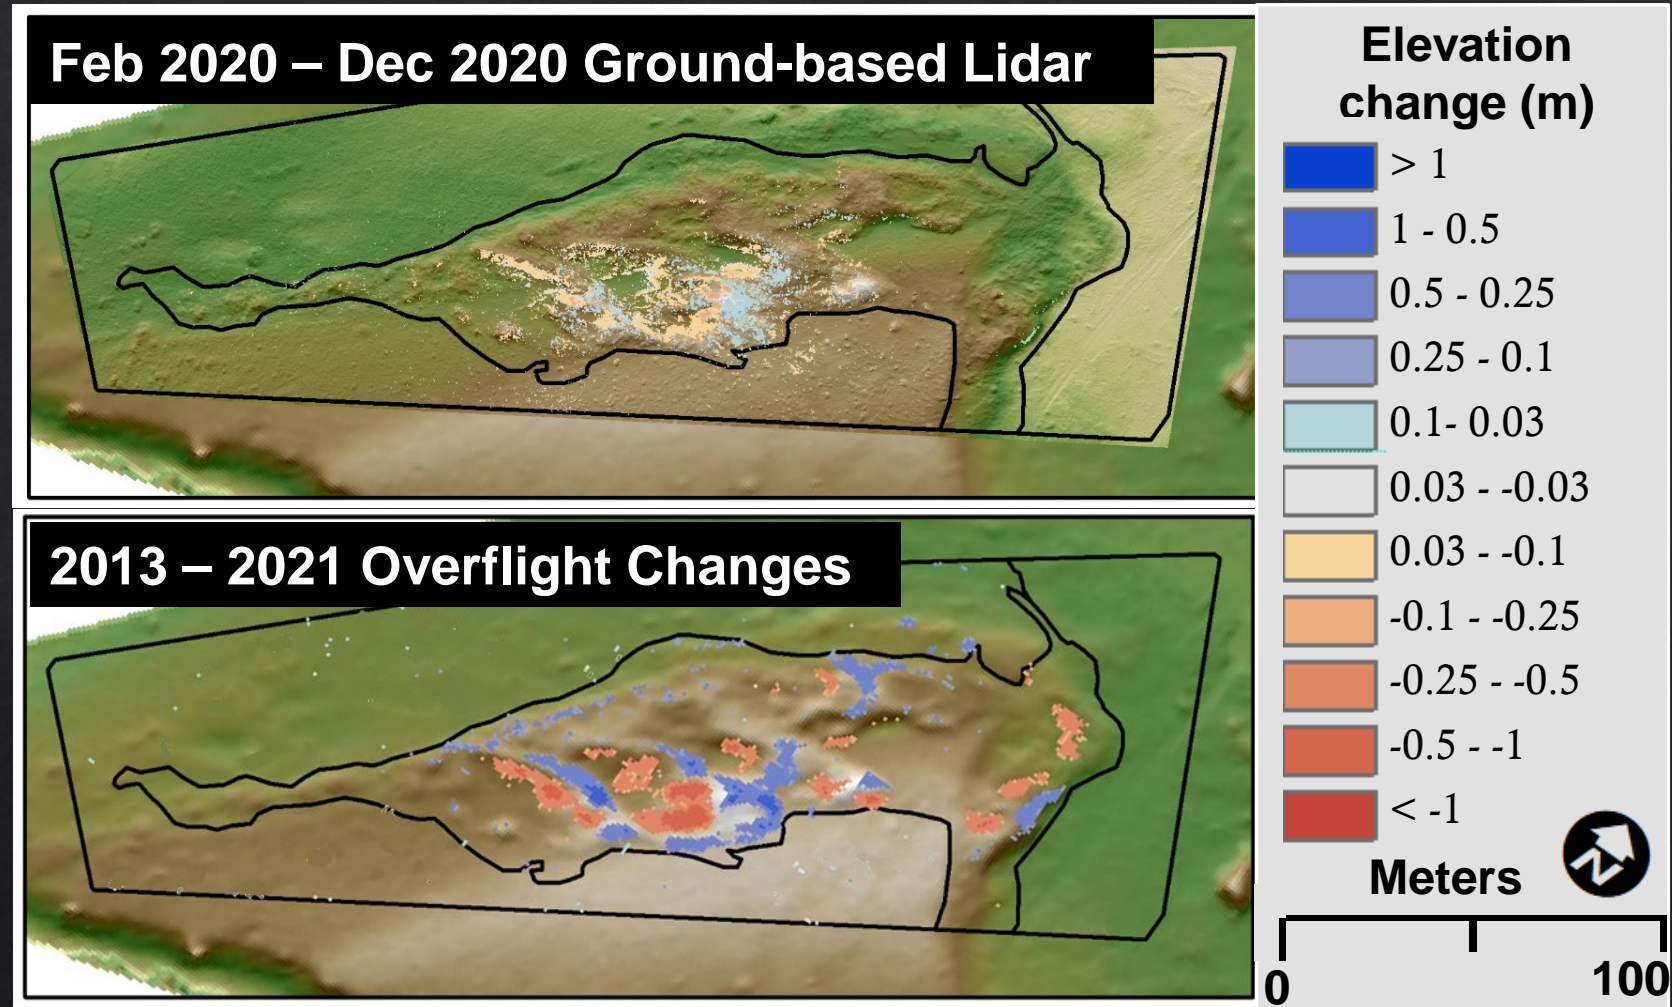

# What change is “measurable” from these data?

Compared to the higher-resolution lidar remote sensing:

- Overflight DSMs have less detail
- Changes need to be larger to be detectable
- Common “patterns” do emerge

# What do change “patterns” mean for river-sourced sand?

## Measure 1: Net Changes

- *In sand, the net surface differences relates to sediment storage*

$$\begin{array}{c} \text{Deposition} \\ - \\ \text{Erosion} \\ = \\ \text{Net Change} \end{array}$$

# Results: River Corridor Landscape Change

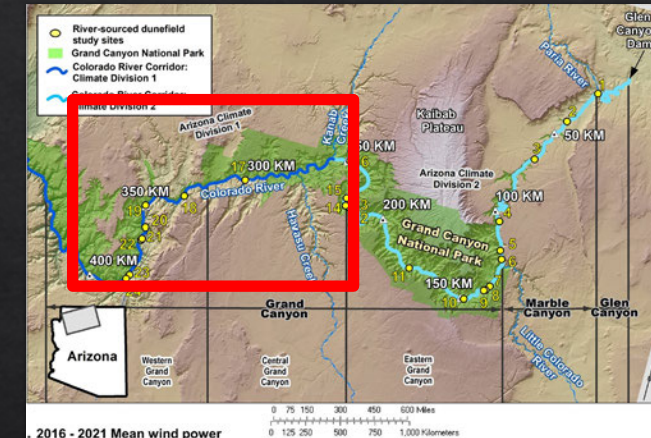

- In general, the dunefield study sites are eroding
  - *Note: ~5 mm change for a football field sized area is over 38 tons of sediment per year!*

# Results: River Corridor Landscape Change

- In general, the dunefield study sites are eroding
- Western Grand Canyon sites are eroding at a higher rate...

# Results: River Corridor Landscape Change

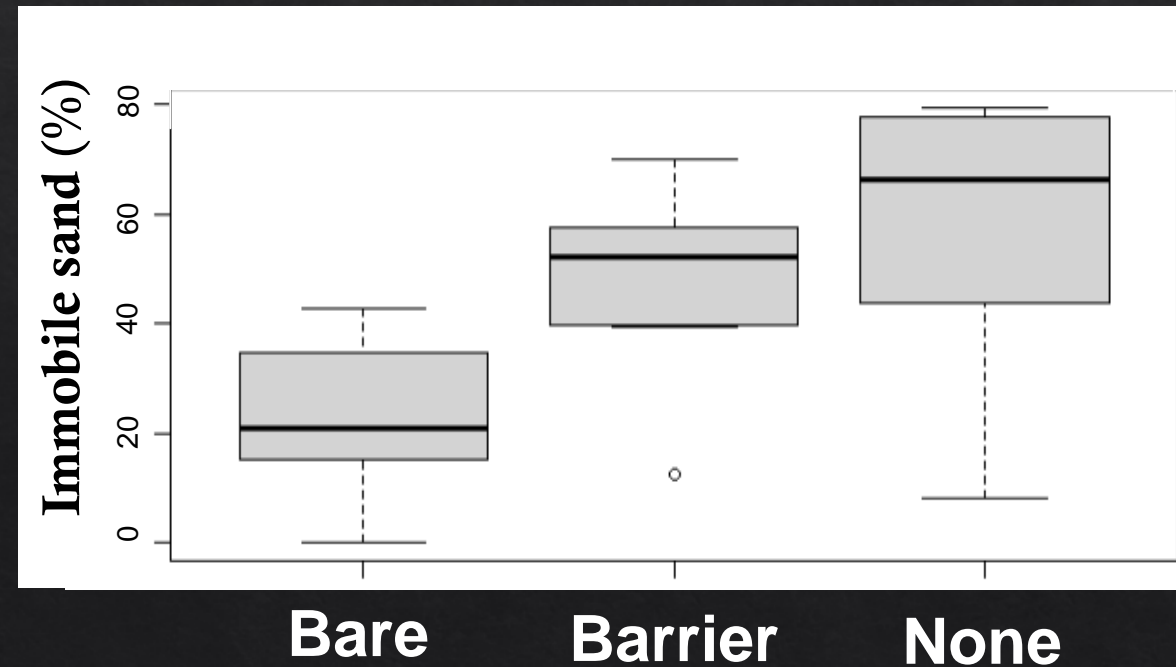

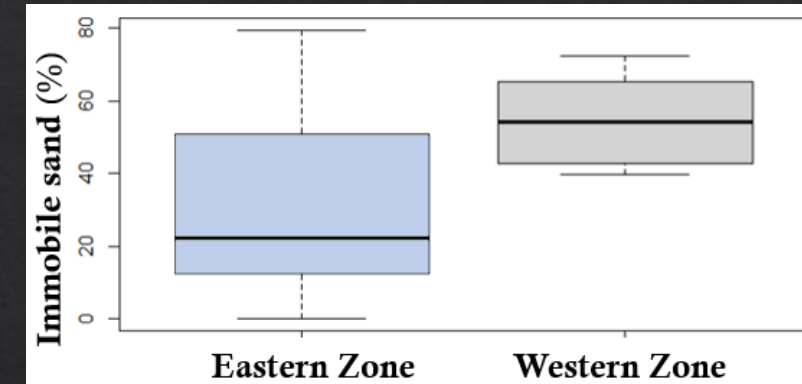

- In general, the dunefield study sites are eroding
- Western Grand Canyon sites are eroding at a higher rate
- The western sites tend to have less “mobile” sediment

# Results: River Corridor Landscape Change

- In general, the dunefield study sites are eroding
- Western Grand Canyon sites are eroding at a higher rate
- The western sites tend to have less “mobile” sediment

# How would less mobility mean more erosion?

- Net volume of sand lost  $\neq$  the total volume of sand moving

- More mobile sand
- Higher total change
- More immobile sand
- Lower total change

# How would less mobility mean more erosion?

Net change is partially driven by changes in supply

Low change imbalance

- High total change
- Low net change

$$\text{Erosion} \approx \text{Deposition}$$

# How would less mobility mean more erosion?

Net change is partially driven by changes in supply

## Low change imbalance

- High total change
- Low net change

$$\text{Erosion} \approx \text{Deposition}$$

## High change imbalance

- Low total change
- Moderate net change

$$\text{Erosion} > \text{Deposition}$$

# Results: River Corridor Landscape Change

- In general, the dunefield study sites are eroding
- Western Grand Canyon sites are eroding at a higher rate
- The western sites tend to have less “mobile” sediment...  
...meaning changes might be smaller, but more is erosional

# Research Question (*Restated*)

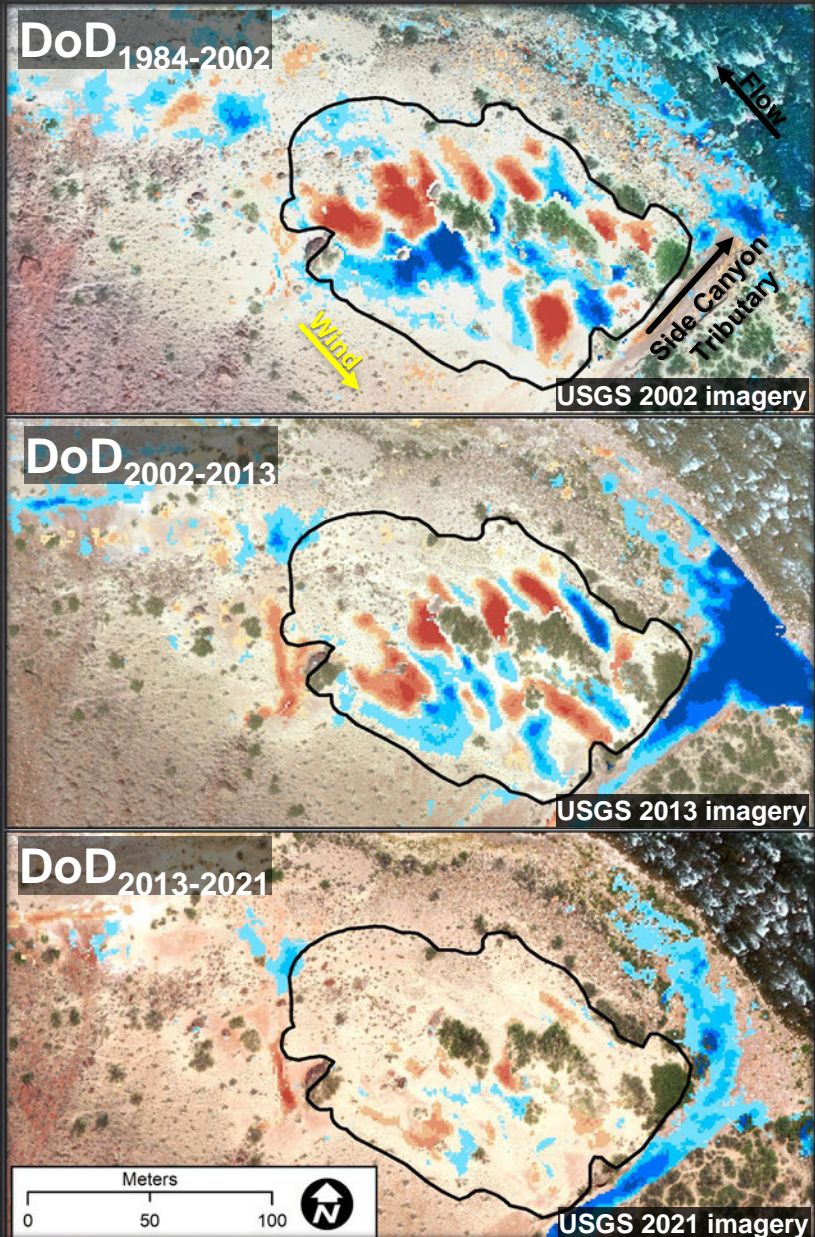

As the river and adjacent landscape become disconnected...

...do river-sourced sands in dunefields have **less total change?**

# Results: Landscape Change 1984 - 2021

*Survey interval and total elevation change*

# Results: Landscape Change 1984 - 2021

## *Survey interval and total elevation change*

# Results: Landscape Change 1984 - 2021

## Survey interval and total elevation change

# Results: Landscape Change 1984 - 2021

## Survey interval and total elevation change

# What's the point?

- River-sourced sand in aeolian dunefields is becoming less “wind mobile”  
...and it is still eroding

# What's the point?

- Where a connection between the river and the adjacent landscape can be maintained, management actions might influence these changes

# Final thought (Finally!)

- The overflight topography can provide useful insight into changes within high elevation river sand

# Thank You
